mineral, and many boats find constant employment in bringing a course anthracite from Kaichau in Liautung to Tientsin. One locality of the mine in Liautung is about lat. 39° 10' N., and long. 121° 25 E. Several kinds, both of anthracite and bituminous, have been seen in marts at the north; and coal dust and refuse is mixed with a little moistened clay at Peking, and made into cakes for the fires of the poor: that which is brought to Canton is hard, and leaves a large proportion of ashes after combustion; during ignition, it throws off a suffocating sulphureous smoke, which prevents the natives using it for cooking. It is employed in the manufacture of copperas from hepatic iron pyrites, according to Du Halde, but is less frequently employed in the arts than it would be if the people knew better how to use it.—*William's Middle Kingdom, p.*242. Coal (Fossil), in Malay, Arana-tanah, literally, "earth-charcoal," has been found in the Malay peninsula, Sumatra, Java, and Luzon, and in Borneo of good quality and suited to economical uses. A seam of the Bornean coal was first discovered in one of the islands in the river of Brunai, where it crops out. It was afterwards found in the mainland, near the banks of the same river, and subsequently in the island of Labuan, about 12 miles from its embouchure. In these places it is at present mined by European skill and capital, and been found, on ample trial, superior to any Asiatic coal hitherto tried. The coal on the left bank of the Borneo river has been traced for several miles into the interior. On the southern coast of the island, coal has been found in the territory of Banjarmasin, and mined by the Dutch. This, from all accounts, is of the same quality as the coal of the northern side, and may be a continuation of the same field, which would make the Bornean coal-fields the largest in the world, after those of North America. Steam navigation has given a value to the coals of Borneo, which, without it, in a country inhabited by rude people and covered with forest, might have lain for ages as useless as the lime and sand-stones in which it is imbedded.—*Crawford Dictionary, page* 195. The Mergui coal was regarded by the Coal Committee as true mineral coal, but of inferior quality. A similar coal is found on the banks of the Tenasserim north of the latitude of Tavoy; but Capt. Tremenheere regards both as superior varieties of lignite. "Lignite or brown coal," says Hitchcock, "appears to be peat which has long been buried in the earth, and has undergone certain chemical changes, whereby bitumen has been produced. Bituminous coal is probably the same substance, which has been longer buried in the earth, and has undergone still further changes." The coal of the great Tenasserim valley appears to have been so long buried in the earth, that the best parts of it are better than ordinary lignite and equal to the inferior portions of bituminous coal, which is true of beds of lignite in other parts of the world. On the banks of the Little Tenasserim, coal of a superior quality is said to exist, and in that direction further examination ought to be made. Of that section of country I have no knowledge from personal observation, but the Coal Committee say: "Eighty miles from Mergui inexhaustible beds of coal of an uniformly good quality occur on the Thian Khan, one of the main branches of the Little Tenasserim. The various beds appear to be what is called cannel coal, remarkable for consisting of upwards of 50 per cent of bitumen, which, to use the words of Mr. James Prinsep, shews it to be a superior blazing material, which is the main point in getting up steam." Coal has also been found on the banks of the Lenhea river, south of Mergui; but of these nothing is known. It is a field for examination.—*Mason.* No indications of bituminous coal have been found in Maulmain Province, but there is reason to believe that anthracite exists under the town of Maulmain itself. In digging a well in one of the Baptist Mission compounds, beneath several alternating beds of sandstone and slate, or shale, more than twenty feet below the surface, beds of carbonaceous matter were reached. One thin bed contained Tremenheerite, which, from Mr. Piddington's analysis is nearly allied to anthracite. Another thin stratum consisted principally of sand and carbonaceous matter, and similar beds are said to accompany the anthracite of America. Below this, is a stratum of shale and carbon containing fossil plants. One was decidedly an impression of a part of a leaf belonging to the palm tribe; and others unquestionably fern leaves, such as indicate the anthracite coal formation in America. One of the ferns, and apparently the most numerous one, cannot be distinguished from specimens of *Neuropteris Scheuchzeri* from the anthracite coal mines of Rhode Island, and Massachussetts in my possession, and others bear a strong resemblance to *Neuropteris Odontopteris* of the American anthracite coal fields that have been figured, but not described. These are the only impressions of ferns that have ever been discovered in the Provinces; but from the bottom of a well deepened last dry season on the margin of the north west corner of Mr. Paterson's compound, an abundance of Tremenheerite was brought up, and it is very probable that the fossiliferous strata are below it; though not the same as those in my compound, the inclination of the strata showing that they are above them. I have also noticed indications of Tremenheerite in the old piles of rocks brought up from a well within Mr. Paterson's grounds at the same corner; and from Mr. Hough's description it would seem that he came to similar strata at the bottom of his well.—*Mason.* The coal of Churra is excellent for many purposes. Dr. Hooker found it generally used by the Assam steamers, and was informed on board

that in which he traversed the Sunderbunds, some months afterwards, that her furnaces consumed 729 lbs. per hour; whereas the consumption of English coal was 800 lbs., of Burdwan coal 840 lbs., and of Assam 900 lbs.—*Hooker Him. Jour. Vol.* II. *page* 303. The coal of the Damoodah valley, adds Dr. Hooker, crops out at the surface at Taldangah; but the shafts worked are sunk through thick beds of alluvium. The age of these coal-fields is quite unknown, and I regret to say that my examination of their fossil plants throws no material light on the subject. Upwards of thirty species of fossil plants have been procured from them and of these the majority are referred by Dr. McClelland in his Reports of the Geological Survey of India, Calcutta, 1850, to the inferior oolite epoch of England, from the prevalence of species of *Zamia*, *Glossopteris* and *Tæniopteris*. Some of these genera, together with *Vertebraria* (a very remarkable Indian fossil,) are also recognised in the coal-fields of Sind and of Australia. I cannot, however, think that botanical evidence of such a nature is sufficient to warrant a satisfactory reference of these Indian coal-fields to the same epoch as those of England or of Australia; in the first place the outlines of the fronds of ferns and their nervation are frail characters if employed alone for the determination of existing genera, and much more so of fossil fragments: in the second place, recent ferns are so widely distributed, that an inspection of the majority affords little clue to the region or locality they come from: and in the third place, considering the wide difference in latitude and longitude of Yorkshire, India, and Australia, the natural conclusion is that they would not have supported a similar vegetation at the same epoch. In fact, finding similar fossil plants at places widly different in latitude, and hence in climate is in the present state of our knowledge, rather an argument against than for their having existed contemporaneously. The *Cycadeæ* especially, whose fossil remains afford so much ground for geological speculations, are far from yielding such precise data as is supposed. Species of the order are found in Mexico, South Africa, Australia, and India, some inhabiting the hottest and dampest, and others the driest climates on the surface of the globe; and it appears to him rash to argue much from the presence of the order in the coal of Yorkshire and India, when we reflect that the geologist of some future epoch may find as good reasons for referring the present Cape, Australian, or Mexican Flora to the same period as that of the Lias and Oolites, when the *Cycadeæ* now living in the former countries shall be fossilised. Specific identity of their contained fossils may be considered as fair evidence of the contemporaneous origin of beds, but amongst the many collections of fossil plants that I have examined, there is hardly a specimen, belonging to any epoch, sufficiently perfect to warrant the assumption that the species to which it belonged can be again recognised. The botanical evidences which geologists too often accept as proofs of specific identity are such as no botanist would attach any importance to in the investigation of existing plants. The faintest traces assumed to be of vegetable origin are habitually made into genera and species by naturalists ignorant of the structure, affinities and distribution of living plants, and of such materials the bulk of so-called systems of fossil plants is composed.—*Hooker Him. Jour. Vol.* I. *page* 7 and 9. In conlusion, we place collectively a list of all the sites of coal at present known to exist on the continent of India.

Burdwan,—Ranigunje. the principal Colliery,...	Discovered by Jones.
Chinakooree, the best quality of coal,	Mr. Betts.
Various other beds have been occasionally opened.	
Adjai Seedpoorie,...	Opened by Mr. Erskine.
Pariharpoor,	
Darbadanaghat, in boring,	By Jones.
Benares road, 149th mile stone, and other places,	Everest.
Hazareebagh,	Colonel Shelton.
Rajmahal,—Patsandeh Baghelpoor,	By Captain Tanner.
Skrigully,	
Hurra,	
Palamoo,—Two principal beds,	Discovered by Mr. A. Prinsep.
Amarath,	In Mr. Homfray's Survey.
Bidjegurh,	By Mr. Highland.
Nerbudda,—Towar river,	Captain Ousely, Lt. Finnis and Dr. Spilsbury.
Hoshungabad,	
Jubulpoor	
Sohagpore,	
Amerkanta,	Captain Jenkins.
Chanda,	Specimens from natives.
Warda nala,	
Cuttack, —Mahanadi,	By Lieutenant Kittoe.
Assam, —Deuphapance, near Bramakoond,	Discoverd by Capt. Wilcox.
Namroop river,	Lieutenant Bigge and Mr. Griffiths.
Suffry or Disung river, near Rungpore,	Mr. Bruce.
Dhunsiree river...	Mr. Scott.
Jumoona river,	
Kossila river, near Gowahate.	
Chilmari and Doorgapoor.	Mr. Scott.
Silhet, — Laour and other sites,	Mr. I. Stark 1815—Jones.
Kasya hills, Chirrapunjie,	Mr. Furnell. Mr. Cracroft.
Sarrarim,	Ditto.
Manipur.—near capital....	Captain Pemberton.
or boundary, Gendah, on Kuenduan river,	Dr. Richardson.
Arracan, —Sandoway District,	Mr. H. Walters.
Kyook Phyoo Island,	Captain Foley.
Moulmein—Anthracite at Bothoung,	Captain Foley.
Southern India,—Travancore Fossil seeds carbonized	Colonel Cullen.
Himalaya, —Kamoan lignite,	Captain Herbert.
Moradabad, lower range,	Mr. Ravenshaw.
Indus, — Cutch,	By Captain Burnes.
Peshawar,	

To these may be added the indications of coal discovered in boring at a depth of 400 in Calcutta and 300 feet at Goga in Guzerat. "In the foregoing situations coal has been traced from Burdwan to the westward, across the Valley of Palamow, and from thence through the district of Sohagpore to Jubulpore, and the neighbourhood of Saka, and the Towa river in the Nerbudda territories, 420 miles distant from Burdwan. Observing nearly the same parallel of

latitude, it is found in the province of Cutch, whilst it is extended in the same line across the centre of India to the N. E. extremity of Assam, forming a zone that stretches from 69° to 93° E. longitude, embraced in an opposite direction between the 20° and 25° N. latitude. Chanda on the Warda river, Cuttack, and Arracan being its southern boundary, whilst the Vale of Callinger west of Allahabad, the Teesta river at the base of the Sikim Mountains, and Upper Assam, from the northern limit. There are however, two situations in which coal has been found distinct from this extensive and well defined belt, namely, Hurdwar and Attok; the first near the source of the Ganges. and the second near that of the Indus. Although situated in the plains, yet both these situations appear to be too closely connected with the Himalaya, and too much detached from the tract now under consideration, to allow of their being considered in common with it. In the infancy of researches of this nature, for such we must as yet consider the state of our information upon the subject of coal, it would be wrong to attach exclusive importance to the peculiar distribution of the mineral just noticed, farther than to observe, that this distribution appears to be highly favourable to all those objects for which coal is desirable. Cutch, the extreme western limit of what here might be named the carboniferous zone, is placed in the most favourable situation for yielding supplies for the navigation of the Indus, the coast of Malabar, and the Red Sea. The Nerbudda river extends 700 miles along the very centre of this zone, and coal in three situations is already found on its banks. 'By minute surveys which have been made of its course, it appears the Nerbudda is navigable for small craft from the sea to eleven miles above Tulluckwarrah, a distant of more than one hundred miles. Here comes a wild and hilly tract which extends to a distance of ninety miles, in some parts of which the breadth of the river is so diminished and its current so obstructed by rocks and shallows, that its navigation is altogether impossible. Above *Hurn-Pahl* or Deer's Leap, it is narrow and rapid, but becomes again navigable above fifteen miles below Chiculdah, and with the exception of a few places where short land carriage might be established, continues so for some distance to the eastward of Hoshingabad.'—(Vide Cent. Ind. vol. 1, p. 5.) The Soane, the Ganges, and the Hooghly, are each intersected by it, and the Bramaputra and probably the Irrawaddy, are extended parallel to it throughout their navigable extent. Now, if on the other hand, this belt had been extended from the Punjab towards the south, scarcely a navigable river but the Indus alone would in such case be approached by it, and the interests of navigation would be as little benefited by the presence of a carboniferous zone, as if the valuable production by which it is distinguished, were buried beneath the table lands of the Himalaya. It is therefore sufficiently encouraging to find the general distribution of coal so favourable, nor need we, as is evident from the Attok and Hurdwar coal, despair of finding supplies available for the navigation of the northern portions of the Ganges and Indus as soon as inquiries are directed in those remote quarters to the objects here in view." The third section of the Report treats of the geological features of that portion of India in which the coal measures occur, and of the difference of level observed therein. At Cherra Ponji a bed of coal is raised on an insulated summit 300 feet above the level of the sea; the accompanying rocks are identical in character with those having a similar relative position to other beds of coal of the same formation, whether above or below the level of the sea. "The insulated situation of the coal measures at Cherra Ponji affords an excellent opportunity for their examination, owing to the great extent of surface which is free from soil and alluvium, so that the geologist has no obstacle to encounter but the dense vegetation peculiar to the climate. The great sandstone composing here as elsewhere the base of the coal measures, forms the lofty front of the mountains facing the plains. The lower beds consist of a coarse conglomerate, resting on greenstone after the manner of similar conglomerates in nearly all countries in which their fundamental rocks have been observed. When we consider that this is not merely the case with the sandstone of the Kasya mountains, but that the whole series of sandstones throughout Central India rest on the flanks of ranges of sienite, greenstone, and basalt, we cannot apply more appropriate language in elucidation of this general feature in our geology, extending as it does over an area of 1,800 geographical miles in length, and 300 in breadth, than the following remarks of De la Beche :—'As we can scarcely conceive such general and simultaneous movements in the interior strata immediately preceding the first deposit of the red sandstone series, that every point on which it reposes was convulsed and threw off fragments of rocks at the same moment; we should rather look to certain foci of disturbance for the dispersion of fragments, or the sudden elevation of lines of strata, sometimes perhaps producing ranges of mountains in accordance with the views of M. Elie de Beaumont.' Had this idea resulted from observations in India, rather than in Europe, it could not have been more appropriate, or formed so as to convey a more accurate notion of the nature and connexions of our red conglomerates. Ascending through the series of beds of this rock in the Kasya mountains, we find the coarser strata occasionally reappear, succeeded again by the normal beds which are fine, durable, and grey coloured. In some places, but especially

when approaching the upper third of the series, the colours become variegated, and ultimately the whole, or nearly so, assume a brick red colour. The higher strata form a barren table-land with lengthy sloping summits extending to the distance of ten miles towards the interior of the mountains. The limestone and coal about to be described, repose in an elevated position on either side of the adjoining summits; whether the rocks of which these last are composed, occupy a superior geognostic position with regard to the coal or not, is somewhat doubtful; but as far as it is safe to determine from inquiries of a partial nature, we may consider the sandstone from the base of the mountains to the higher peaks along their flanks as an uninterrupted series of beds, and consequently, that the coal is a newer rock than the sandstone composing adjacent summits. In the sandstone upon which the coal and limestone immediately rest at Cherra, a bed of boring shells occur composing a considerable portion of the rock in certain places. The shells were of the size and form of the Teredo navalis, but they are mineralized so unfavourably as to render it doubtful to what genus they really belonged. Reposing on the teredinite sandstone near Cherra, a detached accumulation of limestone with alternating beds of sandstone, coal, and shale, disposed in horizontal strata form a precipice about a hundred feet high from the base. Coal, to a thickness of fifteen feet in place, occupies a middle position in these strata. A bed of loose, coarse and sharp sand, five feet deep, forms the roof of the coal, and a layer of soft sandstone, about two feet in thickness, rests directly under the soil upon a bed of clay about twenty feet deep. The clay holds an intermediate position between the roof of the coal and the superincumbent sandstone, it is of yellow colour, but dark in some places, and intersected horizontally with thin layers of gravel, coal, and an iron pyrites of little value, and in small quantity. From their softness these beds are easily, though not uniformly, acted upon by surface water, which peculiarity may have given rise to that waved appearance observed by Mr. Jones and Captain Sage in the Burdwan and Palamow coal fields. "*Silhet Coal District*—The existence of Coal at Burdwan had been known as early as 1804, when it was observed by the officers of a regiment marching across the district. This discovery was communicated to the late Major General Hardwicke, and although the country was at the time depending for supplies of coal on England and New Holland, no farther attention appears to have been directed to the subject until 1809, when the Military Board, having been called upon for information, appears to have reported unfavourably of the quality of the coal in question. "*Arracan.*—Coal has been discovered at Kyuk Phyu in the Arracan district near Oogadong, close to the anchorage of ships. It was first observed by Lieutenant Foley in 1833, and afterwards described by that gentleman and Captain Margrave (vol. II. Asiat. Jour. p. 595). The quality of this coal is good, but the quantity so far as it has yet been discovered is deficient. "At Sandowy, in the same district, Lieut. Mackintosh found coal in the Kingtellie neighbourhood; one specimen of this coal mixed up with silicious matter is said by Mr. Walters to form the substance of an entire hill (vide Jour. Asiat. Soc. II, p 264); iron ores are also said to occur here in considerable quantity. "*Burdwan and Adji Coal Districts.*—The Burdwan coal district is certainly next in importance to that of Silhet. That part of it in which the Collieries are situated is 140 miles N. W. of Calcutta and is traversed by two rivers, the Damuda and and the Adji; the first enters the Hoogley about 25 miles below Calcutta, and the second enters that branch of the Hoogley called Bhagarutty about 70 miles above that city. The point at which the Damuda forms a junction with the Hoogley is 160 miles from the site of the coal mines: whereas Cutwa, the town at which the Adji joins this river is only 110 miles from the mines, while it is 70 miles nearer the great line of navigation on the Ganges, making a difference of 120 miles in favour of the Adji compared with the Damuda, as a line of conveyance to that part of the Ganges for the navigation of which the provision of coal is now chiefly required to be made. As a drawback however from this very marked advantage, there would be a land carriage of 10 miles across the country from the present mines on the Damuda to the Adji; but as these rivers extend parallel to each other for the distance of 40 miles (according to Arrowsmith's map), the most favourable portion of this space might be selected for the construction of a rail road from the present mines on the Damuda to boats on the Adji. "The advantage of the Adji compared with the Damuda as a line of conveyance, has here only been considered with reference to coal already worked; but the assistance which the Committee is receiving from the communications of Captain Forbes with Mr. Erskine, a gentleman residing on the spot, leaves scarcely a doubt as to the existence of good workable coal close to the Adji itself; and in a letter received from Mr. E. dated 6th July 1837, four situations are pointed out in which good coal may be raised, and delivered into boats at an expense of from ¼ to ½ an anna per maund. He moreover announces the dispatch of 2,000 maunds which will be delivered at Cutwa, at the rate of 3 annas per maund including all contingent charges. "The first situation in which Mr. Erskine points out coal is, Mamamudpore, two coss south of the Adji Ghat at Seedpooria;—land carriage per maund ⅛ths of an anna, but this coal as it appears on the surface of a ravine in which there is a stream of water is somewhat heavy and hard. The quality may

probably improve by pursuing the vein to a distance from the surface, or by sinking a shaft, better beds may be reached. "The second locality pointed out by Mr. Erskine, is a little to the west of the first, and 2½ coss from the same Ghat,—carriage per maund ¼ of an anna, quality better than that of the first. "The third place, and that from which Mr. Erskine himself has been in the habit of taking coal is Pariharpore, a good deal west of the other situations and only two coss, Mr. Erskine thinks, from the Damuda, and four coss in south-westerly direction from Durbadanga, the nearest Ghat on the Adji, which is one coss above Seedpore,—carriage 1½ anna per maund. This is a lighter and more brittle coal than either of the others, presenting a glistening and resinous lustre, and on exposure is inclined to crumble. "Mr. E. says that to the eastward of Mammudpore, all traces of coal or indeed any rocks disappear, while on the contrary the quality of the mineral improves on advancing towards the west. Mr. Erskine adds, that the last time the late Mr. Jones visited Elambazar, he said that in his borings about Beerkoolthee, near the Seedpore and Durbadanga Ghats on the Adji, he had met with coal even superior to that on the Damuda, and wished much to open a mine in that situation in conjunction with the late Mr. D. Erskine. "*Palamow Coal-field.*—The coal field of Burdwan is connected by means of what would seem to be the shattered remnants of coal measures with another principal coal field in the valley of Palamow on the opposite side of the Mongyr mountains. To the notice of this, as next in importance, we may at once proceed. "Coal has been known to exist in Palamow still earlier than the period at which it was brought to notice at Burdwan, as appears from a spot marked coal mine on Arrowsmith's map, but it was not till after the introduction of steam navigation that the fact excited any interest, when the late Mr. A. Prinsep, then the principal civil officer of the district had the merit of first directing attention to its importance; since that period, Palamow has been frequently visited by scientific and practical men, from whose reports the following particulars are gleaned. "The coal fields of Burdwan and Palamow are separated from each other by the prolongation to the eastward of the Vindhya chain, to which they bear a similar relative position, both reposing in low hills of sandstone, the one at the southern, and the other at the northern foot of the chain. "The valley of Palamow, situated at the source of one of the great branches of the Soane, is scarcely raised at its outlet above the general level of the plains of India, but is inclined with a slight ascent to the granitic mountains by which it is surrounded, except towards the north, at which side the Caile or Palamow river joins the Soane. The length of the valley from north to south may be about 70 miles, but its breadth is much contracted by the approximation of steep granitic hills on opposite sides, between which small diversified valleys are extended laterally. *Sakar river.*—Captain Ousely has recently brought to light a third site of coal in the Nerbudda, of excellent quality and inexhaustible quantity, within eight miles of Chukeli and twelve or fourteen from Gorahwarah proper on the Sakar. "What has been said in another section regarding the navigation of the Nerbudda, from Baug to Hoosingabad, a distance of three degrees, may enhance the value of the two last mentioned discoveries, but the great difficulty is the rapids of the Nerbuddah. "*Rajmal.*—At Rajmal, coal has been found by Captain Tanner in two situations, viz. at Sicrigully on the banks of the Ganges, and at Hurrah, twenty five miles distant. With regard to Sicrigully this place has been recently visited by Lieutenant Don, who reports to the Committee that as far as he and Lieutenant Egerton who accompanied him, could determine, no coal exists at the foot of the Mootee Jarma waterfall where it was supposed to have been observed by Captain Tanner."—*Report of Coal Committee.*

(2726) COBÆA SCANDENS. This is a fast growing creeper, the flowers of which are purple, and the stems attach themselves to any rough surface, like some of the Cereus species, and is well adapted for screening walls.—*Riddell.*

(2727) COBÆACEÆ, a small natural order of Plants.—*Engl. Cyc. Vol.* II. *page* 40.

(2728) COBITIS, a genus of Fishes belonging to the Abdominal *Malacopterygii* and family *Cyprinidæ.* This genus includes the Loaches.—*Engl. Cyc. page* 41.

(2729) COCCIDÆ, (of Leach) the *Gallinsecta* (of Latreille), a family of Insects placed by Latreille and others at the end of the *Homoptera.* The insects belonging to this family live upon trees or plants of various kinds: they are of small size, and in the larva state have the appearance of oval or round scales, hence they are called Scale Insects. They are closely attached to the plant or bark of the tree they inhabit, and exhibit no distinct external organs. At certain seasons, when about to undergo their transformation, they become fixed to the plant, and assume the pupa state within the skin of the larva. The pupa of the males has the two anterior legs directed forwards, and the remaining four backwards; whereas in the females the whole six are directed backwards. When the males have assumed the winged or imago state they are said to issue from the posterior extremity of their cocoon. In the spring time the body of the female becomes greatly enlarged, and approaches more or less to a spherical form. In some the skin is smooth, and in others transverse incisions or vestiges of segments are visible. It is in this state that the female receives the embraces of the

male, after which she deposits her eggs, which are extremely numerous. In some, the eggs are deposited by the insect beneath her own body, after which she dies, and the body hardens and forms a scale-like covering, which serves to protect the eggs until the following season, when they hatch. The females of other species cover their eggs with a white cotton-like substance, which answers the same end.—*Eng. Cyc. Vol.* II. *page* 43.

(2730) COCCOLOBA, a genus of plants belonging to the natural order *Polygonaceæ*.—*Eng. Cyc. Vol.* II. *page* 45.

(2731) COCCOTHRAUSTES, a genus of Insessorial Birds belonging to the family *Fringillidæ*.—*Eng. Cyc. Vol*, II. *page* 45.

(2732) COCCULUS, a genus of Plants belonging to the natural order *Menispermaceæ*, consisting of climbers, whose leaves are usually more or less heart-shaped, and the flowers small, and either white or pale green, in loose panicles or racemes; in most cases they are diœcious, and are always very minute. The species are usually powerful bitter febrifuges.

(2733) COCCULUS ACUMINATUS, Coromandel and Bengal. Syn. M. polycorpon, (Rox. vol. iii. p. 816.) Tiliacora racemosa, Colebrooke, Trans. Lin. Society, xiii. 67.—*O'Shaughnessy, page* 202.

(2734) COCCULUS BAKIS, Senegal Root, diuretic and very bitter, used in intermittents and gonorrhœa.—*Ibid.*

(2735) COCCULUS CRISPUS, a twining plant found in Sumatra and the Moluccas, with a tubercled or warted stem, it is employed by the Malays for the cure of intermittent fevers. Owing to its intense bitterness and twining habit it was called *Finus felleus* by Rumf. Another plant, the *Menispermum fenestratum* of Roxburgh, is in great repute among the Cingalese, who slice it, steep it in water, and swallow it along with the infusion as a stomachic.—*Engl Cyc. page* 46.

(2736) COCCULUS CINERASCENS, Rio Janeiro. Root, used in intermittent and liver diseases.

(2737) COCCULUS CORDIFOLIUS, Menispermum cordifolium, see *Fl. Ind.* iii. *p.* 811.

Guluncha, Gudancha, Hind. | **Goolwail,** Duk.

This is one of the most common and valuable plants in India. The stem is twining, perennial, succulent, running over the highest trees. The root is large, soft, and spongy, and when fresh is used extensively by the natives of Bengal, being mixed with sour rice gruel, and sugar, for the cure of heat of urine of gonorrhœa. On the mode of preparing the guluncha in its various forms, and its uses in disease, some very curious information is given by the Dewan Ramcomul Sen, in a paper published in the Trans. Medical and Physical Society of Calcutta, 1827, vol. iii. p. 294. An extract called *Palo* is procured from the stem, and is used dissolved in water for the same purpose. The stems, roots and leaves are bitter, and afford a decoction called *Pachana*, much used as a bitter tonic, in convalescence from fevers and acute diseases generally. The *Palo* is prepared by cutting the stem into small pieces, which are cleaned and bruised in a mortar, then soaked in water for 24 to 48 hours. The mass is then squeezed between the palms of the hands, and the woody particles separated from the fluid, which is strained through a cloth. The solution is evaporated to dryness before the sun, and when dry the residue resembles sugar; the dose is half a rupee to one rupee weight, taken with sugar, milk, and rice gruel. The decoction *Pachana* is made from 2 to 5 rupees weight of the stem cut into small pieces, bruised in a mortar, and boiled with a pound (½ a seer) of water down to two ounces; this is then strained and drunk with honey. An infusion in cold water is also prepared, and is much employed in the treatment of cutaneous diseases. The species employed by Mr. Piddington, he names the *Menispermum verrucosum* and *glabrum*, neither of which properly refers to our article. The *M. verrucosum*, though cultivated in the Botanic Garden, is not indigenous, it is a native of Java and Amboyna, and is now known to be the *Funis felleus* of Rumphius. It is a much more powerful bitter than the guluncha. The alcoholic extract Mr. Piddington described as likely to prove of great value in the treatment of intermittent fever. The highly satisfactory effects of *M. verrucosum* in Java and Manilla promised indeed similar advantages from the use of guluncha here. Dr. Hardie of Oudepore and Dr. Stewart of Calcutta used the extract in several cases of intermittent fever in 1829, and reported on it very favourably. Our article, in common with all the order, should be collected during the hot season, when the bitter principle is most abundant and concentrated. Dr. O'Shaughnessy, in several trials made at the Calcutta College Hospital, found the guluncha to be a very useful tonic, but could scarcely attribute to it any very decided febrifuge effect. The decoction, or cold infusion used in the same manner as sarsaparilla was of very great utility in the treatment of several cases of chronic rheumatism, and of secondary venereal affections. Its action is decidedly diuretic and tonic in a very high degree. The Roots and Stems are the officinal part given in the form of Extract, tincture, infusion, and decoction.—*O'Shaughnessy, pages* 198—200. The heart-leaved Cocculus is a twining shrub with scabrous corky bark, and broad cordate leaves. The flowers are mostly whitish green and the berries scarlet. This plant possesses febrifuge properties. The Cocculus Cordifolius or Goluncha Creeper is found especially on neem trees, whence it is called also nim gilo ka

sath, its roots and stem are intensely bitter. Mr. Piddington found that the bitterness varied according to the season when the plant was gathered. No later analysis has been made of Goluncha than that of Mr. Piddington, whose experiments indicated starch, mucilage, extractive and a crystalline substance. Dr. H. H. Goodeve considered extract of Goluncha, if not equal to Quinine as a febrifuge, at least as good as the common Cinchona bark and much better than Chiretta. Some of the dispensaries in the North-West report very favorably of this substance. There are however no good recent accounts of it, and the substance certainly demands further examination as also does Cocculus Crispus, the Menispermum Verrucosum of Roxburgh, to which Mr. Piddington called attention in 1829. The extract is undoubtedly a useful tonic and its decoction has a great reputation among native practitioners in old intermittents, when the dose is about 1½ oz. thrice daily. A tincture is prepared from the stems, 8 oz. and spirits one pint. The dose of it is 2 drams to half an ounce. That of the extract is one dram to three drams daily.—*Ind. Ann. Med. Sci. for Apl.* 1856. *p.* 392. The Extract of Gulaucha is a very valuable bitter tonic; the preparation given by Dr. O'Shaughnessy is the Palo of the native physicians. Dose, one drachm and a half or three drachms, in divided portions daily, diffused through milk, and the taste disguised by sugar.—*Beng. Phar. p.* 290.

(2738) COCCULUS CRISPUS. Syn. *Menispermum verrucosum*, grows in Java and Amboyna. The whole is extremely bitter, and is used with complete success by the Malays as a febrifuge remedy.—*O'Shaughnessy.*

(2739) COCCULUS FIBRAUREA, Cochin-China, and China; used by the Malays in agues and liver diseases.—*O'Shaughnessy.*

(2740) COCCULUS INDICUS, Indian Berry.

Kakmari kee-beenge, Jermaee, Hind.	Kakichempoo vittiloo, Tel.

Anamirta Cocculus: this is a kind of seed imported from the East Indies under the name of Cocculus Indicus Berries, which possess a powerful bitter poisonous principle, that, according to Goupil, exists principally in the kernel. The plant is found in the forests of Malabar, and when transplanted to the botanic garden, Calcutta, grew in a few years so as to extend over a large mango-tree, with a stout woody stem as thick as a man's wrist, covered with deeply cracked, spongy, ash-coloured bark. The leaves were very exactly cordate, entire, obtuse, or emarginate, of a hard texture, shining on the upper surface, and from 4 to 12 inches long, by from 3 to 8 inches broad. This plant is the *Menispermum Cocculus* of Linnæus, the *Cocculus suberosus* of De Candolle; but according to Messrs. Wight and Arnott, it does not properly belong to the latter genus, having the stamens combined into a central column and no corolla. They call it *Anamirta Cocculus*, under which head it will be found described. The *Cocculus Indicus* berries are never used internally in the practice of medicine, but an ointment formed of the powdered berries is very efficacious in some cutaneous diseases, such as *Porrigo Capitis* and *Sycosis Menti*. It speedily allays the inflammatory state; but its employment requires great care. Creosote will probably supersede it in such cases.—*Eng. Cyc. p.* 48. Dr. Royle tells us that Cocculus Indicus, is the fruit of a climbing plant common in the mountainous parts of the Malabar coast, whence our supplies, and they are large, are now all derived through Bombay, Madras, and Ceylon. But formerly these berries reached Europe by the Red Sea and the Mediterranean, whence they were called Grana Orientis by Ruellius, 1536, Coque du Levant, by Pomet, &c. There is no proof, though it is probable, that they were known to the Arabs. The Mahizuhra (Fish-poison) of Rhases, Serapion, and Avicenna, and referred by Sprengel to these berries, seems to have been a plant and its bark, "qua juvat in doloribus juncturatarum et contortione digitorum." (Serapion.) Plempius coined the name *Icthyoctonum*, to indicate "fish-poison." The plant yielding these berries was ascertained by Dr. Roxburgh. It was named *Anamirta paniculata* by Colebrook, and subsequently *A. Cocculus* by Wight and Arnott; the latter name has been adopted by the Edinburgh Pharmacopœia. It was the *Menispermum Cocculus* of Linnæus. The name Cocculus is probably derived from the Tamul *Kukacollie*, which signifies *crow-killing*, as does the Sanscrit *kakmare*. The Cocculus plant is a powerful climber, with ash-coloured, deeply cracked, corky bark, whence the plant was called Cocculus suberosus. The leaves are stalked, large, broad-ovate, or rather roundish, truncated or somewhat cordate at the base, acute at the apex, firm in texture, soft and downy when young, with 5 digitate ribs,—petioles a little shorter than the leaves, tumid at both ends. Flowers diœcious, in lateral compound racemes. Calyx of 6 sepals in a double series with 2 close pressed bracteoles. Corolla none. Cocculus berries were described by Dale as being kidney-shaped and something like bay-berries, but somewhat smaller. They are blackish-brown, and wrinkled externally, with the outer coat thin and dry, and within it is a white, woody, bivalvular shell, enclosing the whitish, semilunar, oily, and very bitter-tasted seed; which never fills the whole of the cavity, but, this in old seeds, is sometimes entirely empty. "The kernels should fill at least two-thirds of the fruit." E. P. *Chem.* The kernels of Cocculus indicus were analysed by Boullay, most recently by Couerbe and Pel-

letier, who obtained *Picrotoxine*, Resin, Gum, Fatty acid, and a Waxy matter, Malic acid, Mucus, Starch, and Salts. In the shell they obtained two alkaloids, but in small quantity, which they called Menispermia and Paramenispermia. But the nucleus being the part used, it is necessary to notice only its active principle. *Picrotoxine* is colourless, crystallizes in needles, sometimes in silky filaments, in plates, and in rhombic prisms. Its taste is intensely bitter. It is soluble in 150 parts of water at 75° F., and in 25 of boiling water, in 2 of Ether, and in about 3 parts of Alcohol. It is insoluble in both the fixed and the volatile oils. It does not combine with acids, but it is soluble in Acetic acid, and as it forms combinations with alkalis, it is therefore considered to be of the nature of an acid. It consists of C_{12}, H_7, O_5. To obtain it, Dr. Christison recommends, to separate the oil first from the kernels by expression, then to exhaust the residuum by percolation with rectified spirit, which is then to be distilled off. The residue is agitated with boiling water and a little H Cl. The dissolved Picrotoxine may be obtained, on the water cooling after moderate concentration. *Action. Uses.* Poisonous; used for taking fish and game, and employed by unprincipled brewers for adulterating porter, being unblushingly recommended by Childe and by Maurice in their books "on Brewing." It is used chiefly in the form of a bitter extract, known by the name of B. E., *black extract*, which is ostensibly prepared for tanners. (*v.* Cycl. of Pract. Receipts.) It produces giddiness, tetanic convulsions, and coma: applied externally, in powder, it destroys vermin, and is useful in scabies, ringworm, and porrigo.—*Royle.*

(2741) COCCULUS PALMATUS. *Syn.* Menispermum palmatum. Cocculus colomba.

Colombo ke jur, HIND. | Colombo root, ENG.

A native of the shores of Oizo and Mozambique, introduced into Madras, and now successfully cultivated in the Calcutta garden. The root is common in the bazars, being brought from Ceylon, whither it comes from Africa. Colombo having been long the intermediate stage in the traffic, has given its name to the root. In commerce, Colombo root is met in slices of one to two inches diameter, half an inch thick, often perforated in the centre, much wrinkled, greyish externally, bright yellow within; the taste is excessively bitter, smell heavy, powder of a greenish grey colour, and very apt to attract moisture from the air. The commerical parcels are often adulterated with the roots of the *Costus indicus, C. speciosus and C. arabicus*, (Kust, Kushmut, Putchuk, Keemooko, *Vern.*) with *Bryony* dyed with turmeric, and with the root of another species of *Cocculus*. Colombo root is one of the most valuable tonics we possess; it seldom occasions any unpleasant sensation in the stomach or alimentary canal; it improves the appetite and digestive powers, does not costipate, and though destitute of absolute febrifuge qualities, is one of the best remedies for persons convalescent from fevers. The dose of the powdered root is fifteen grains to one drachm. The tincture is the best form, as the spirit dissolves all the active, and removes none of the inert ingredients; the dose of the tincture is from one to three drachms. The watery infusion is very apt to spoil, on account of its containing a large proportion of starch. A root called American Colombo is very commonly met with. It is the root of the *Frasera Carolinensis*, or *Walteri*, a native of North America, of the natural order Gentianeæ. It may be at once distinguished by the absence of starch, in consequence of which it does not give a blue colour with tincture of iodine. It also contains tannic acid, which may be detected by the deep black colour struck with the permuriate of iron. The true Colombo contains no astringent principle. Another spurious Colombo arrives in Europe from Algiers, and may also be distinguished by the tests above-mentioned. The Costus speciosus and Arabicus are at once known by their very different appearance, and violet smell. The adulteration by *bryony* is rare. This root is white, and cold water will remove the turmeric employed to dye it yellow. But even to the eye of an inexperienced person the characters of true Colombo once carefully examined, are so decided that no mistake can be apprehended. It is not improbable that the roots of other species of Cocculus may resemble the Colombo sufficiently to be substituted for the latter, not only in trade, but in medicine. Experiments with this family are however peculiarly dangerour, on account of the presence in some of the bitter and very poisonous picrotoxic acid. The root is used in infusion, tincture, and compound tincture.—*O'Shaughnessy, pages* 196-198.

(2742) COCCULUS PLATYPHYLLUS, Brazil.

(2743) COCCULUS VILLOSUS, a plant common in the hedges of Bengal, with variable downy leaves and axillary solitary female flowers, succeeded by deep purple berries the size of peas, is a species of considerable importance to the Hindoos. The juice of its ripe berries makes a good durable bluish-purple ink, according to Roxburgh, who adds some further particulars concerning its uses;—"A decoction of the fresh roots, with a few heads of long pepper, in goat's milk, is administered for rheumatic and old venereal pains; it is reckoned heating, laxative, and sudorific. The fresh leaves taste simply herbaceous; rubbed in water they thicken it into a green jelly, which is sweetened with sugar, and drank, when fresh made, to the quantity of half a pint twice a day, for the cure of heat of urine in gonorrhœa. If suffered to stand for a few minutes, the gelatinous or mucilaginous parts separate,

contract, and float in the centre, leaving the water clear, like Madeira wine, and almost tasteless. Curry is made of the leaves, for people under a course of its roots, or jelly of the leaves." —*Engl. Cyc. Vol.* II. *p.* 47.

(2744) COCCUS, *Linn.* Order *Hemiptera.* The entire insects are the Cochineal. Several of the genus Coccus are used as dyes; as the Kermes insect, or *Coccus Ilicis*, found on the Ilex Oak; the *Coccus Lacca*, or Lac insect, found in various trees and shrubs in India, much used as a substitute for Cochineal and its Resin (Shell-Lac) for various purposes; the *Coccus polonicus*, found on the root of *Soleranthus perennis*. Something similar is found on the roots of a plant in the marshes of Herat. (*Burnes.*) The true *grana fina* of the Spaniards, is found in the cool parts of Mexico, as near Oaxaca, whence one kind of Elemi is obtained. The *grana sylvestra*, an inferior species, is found in hot parts, as near Vera Cruz, and in Brazil. The female of the Cochineal insect is alone collected from off the Cactus plant where the impregnated females have previously been placed by the natives of Mexico to produce their numerous young. These, when matured, are brushed off, and killed by artificial heat. Three harvests are annually collected. The *Silver* and *Black* varieties of the *Grana fina* are known. The insects are oblong, roundish, plano-convex, from one to two lines in length, wrinkled, the former of a colour resembling silver-paper, owing to fine down with which they are covered, and by which the genuine may be distinguished from any imitation of the colour with powdered Talc, &c. They are of a purplish-grey colour, while the *black* variety is without bloom, and of a dark-reddish colour. An inferior kind (granilla) made up of smaller insects, and broken fragments is also sold. Cochineal, when powdered, is of a carmine colour, without odour, but having a slightly-bitter taste. It contains some fatty matters, with a brilliant colouring principle which has been called *Cochenilline*, making it valuable as a dye. It is used for giving colour to some tinctures.—*Royle.* This insect feeds upon a particular kind of Indian fig, which is cultivated for the express purpose of rearing it.—*Eng. Cyc. Vol.* II, *page* 44. The Cochineal insect was introduced into Java a few years ago, as a Government experiment, and apparently with more success in its production than in British India, for as long ago as 1844 it was exported from Batavia to the estimated value of 93,319 guilders.—*Crawfurd Dict. page* 112. After prolonged efforts on the part of Dr. James Anderson and Berry of Madras in 1795, the Sylvestre or wild species of the Cochineal insect was introduced into Bengal by Capt. Neilson of H. M. 74th Regt., and throve rapidly on the Cactus indica, the indigenous opuntia, the country Nopal, and between 1800 and 1807, 74,366½ lbs. of the Cochineal amounting to Rs. 142,916 in value was shipped to England, but at a loss, as the wild species was greatly inferior to the true.—*Royle Prod. Re. page* 57.

(2745) COCCUS LACCA. But we are not alone indebted to the Coccus tribe for the dyes they yield; the substance called Lac is also procured from one of these insects, the *Coccus Lacca*. This species inhabits India, where it is found on various trees in great abundance. "When the females of this Coccus have fixed themselves to a part of the branch of the trees on which they feed (*Ficus religiosa* and *F. Indica*, *Butea frondosa*, and *Rhamnus Jujuba*), a pellucid and glutinous substance begins to exude from the margins of the body, and in the end covers the whole insect with a cell of this substance, which when hardened by exposure to the air becomes lac. So numerous are these insects, and so closely crowded together, that they often entirely cover a branch; and the groups take different shapes, as squares, hexagons, &c. according to the space left round the insect which first began to form its cell. Under these cells the females deposit their eggs, which, after a certain period, are hatched, and the young ones eat their way out." (Kirby and Spence, Vol IV, p. 142.) —*Eng. Cyc. Vol.* II, *page* 44.

(2746) COCCUS POLONICUS is another species which is used in dyeing, and imparts a red colour. It is now chiefly employed by the Turks for dyeing wool, silk, and hair, and for staining the nails of women's fingers. (Kirby and Spence, vol. I, p. 320).—*Eng. Cyc. p.* 44.

(2747) COCHINEAL.

Conchenilje, Dut.	Kermij, Pers.
Cochenille, Fr.	Cochenilha, Port.
Koschenilje, Ger.	Konssenel, Rus.
Kermij Guz, & Hind.	Cochinilla, Grana, Sp.
Coccinigliia, It.	Cochineel poochie, Tam.

Cochineal is met with in small rugose inodorous grains, commonly of a deep mulberry colour, and covered more or less with a whitish down. They are the female of a small insect (*Coccus cacti*), a native of Mexico, and feed on the leaves of the *Cactus cochinellifera*. This article, although yielding a crimson solution, is generally used for dyeing scarlet. Cochineal is imported into Bombay from England; two sorts are distinguished, *Silver* and *Black* cochineal: the former is considered of superior quality to the latter. Cochineal is extremely rich in the finest red colouring-matter, and has been long employed in scarlet dyeing and in the manufacture of carmine. The chief use of Cochineal is the dyeing of scarlet: the fine colour which it yields being converted to this tint by means of chloride of tin usually called Muriate of Tin, and by the dyer Tin Spirits. The insect which constitutes Cochineal feeds chiefly upon the *Cactus cochinellifera* but also on *C. opuntia* and other species. The female insect only is collected. Several varieties are distinguished in commerce, and have different degrees of value attached to them, dependent chiefly upon the dif-

ferent methods employed to kill and dry the insects. When dried they resemble small grains scarcely so large as a pepper-corn, ovate, convex above, plane below, transversely furrowed, externally blackish-brown, but as if dusted with a white powder, light, friable, the internal substance consisting of extremely small grains, obscurely purple, but when reduced to powder of a rich purple. Inodorous, but with a bitter-sweet acrid taste. They impart to water or alcohol by digestion an intensely red colour. The colouring principle is termed Carmine. Adulterations are effected either by mixing old insects consisting of the mere skin or grains artificially prepared with the genuine. Cochineal has hitherto been employed mostly as a colouring material either of tinctures or of other things the nature of which it is wished to disguise; but lately it has been stated to possess diuretic and antispasmodic powers, and to be useful in pertussis, or hooping-cough. Its claim to this character requires yet to be established by further evidence.—*Engl. Cyc. page* 48. At the Madras Exhibition of 1857, the *Cochineal* exhibited from *Chittledroog* was from "*Coccus cacti.*" The cochineal exhibited was "silver grain." It forms a very fine and permanent dye in red, crimson, scarlets. It answers on wool and silk, but not on cotton. It is a most expensive colour, and is rarely in the hands of the dyer, but if supplied to him, he understands the method of using it. The attention of the East India Company was for many years directed to the production of this dye, but with little success. Insects were with much difficulty procured, and introduced about 50 years ago, and a large quantity was produced under the superintendance of Dr. Anderson, and encouragement held out by the Madras Government, but unfortunately the insect turned out to be the wild species. What was exported, proved to be small and deficient in colouring matter, and very inferior to any brought from new Spain. The Court of Directors offered £2000 for the introduction of the true Mexican Cochineal, but this never was accomplished.—*M. E. J. R.*

(2748) COCHLOSPERMUM, a genus of Plants placed by Lindley in the natural order *Cistaceo*, found in Asia, Africa, and South America. Botanists usually place it amongst the Theads (*Ternströmiaceæ*); but its parietal placentæ, acrisomerous flowers, and curved embryo lying in the midst of albumen, seem fatal objections to that association.—*Engl. Cyc. page* 49. Dr. Hooker, in his Himalayan travels, writes that these trees have curious thick branches which spread out somewhat awkwardly, each tipped with a cluster of golden yellow flowers, as large as the palm of the hand, and very beautiful: it is a tropical Gum-Cistus in the appearance and texture of the petals, and their frail nature. The bark abounds in a transparent gum, of which the white ants seem fond, for they had killed many trees. Of the leaves the curious rude leaf-bellows are made, with which the natives of the Assam valley hills, smelt iron.—*Hooker Him. Jour. Vol.* I, *page* 53.

(2749) COCHLOSPERMUM GOSSYPIUM. Yellow-flowered cotton tree. *Syn.* Bombax Gossypium, L. *Off-product.* Kutira gum of the bazars. Dr. Roxburgh describes this tree as common on the Arracan mountains. It is a large tree with downy shoots. It occurs also in Bundlecund, on the hills round and near Adjigurh and Kalingur, as well as on those near Hurdwar, and the Kheree pass.—*O'Shaughnessy, page* 225. Leaves 5-6 inches long, 5-lobed; ovary beneath on cylindrical downy stalks. Panicle terminal. Flowers large, and bright yellow, and appear in March and April, when the tree is destitute of leaves. Capsules large, containing a silky cotton, used merely for stuffing pillows. The trunk yields the gum Kuteera, which in the North-Western Provinces of India, is substituted for Tragacanth. —*Engl. Cyc. p.* 49.

(2750) COCHLOSPERMUM SERRATIFOLIUM.—A tree resembling the gossypium, but with the lobes of the leaves serrated.

(2751) COCK. One species of the genus Gallus is found in the wild state in the Malay Peninsula, two in Sumatra, two in Java, and one in the Philippine Islands. It is remarkable, however, that no bird of the genus in the wild state is to be found in Borneo, Celebes, or any island of the Molucca Sea. Several of these supposed species are probably the same. The two of Java are distinct species; they will pair, but the progeny is a male, a beautiful bird kept by the wealthy Javanese as an ornament of their poultry-yards, under the name, well known to them, of Pakiser. The wild fowl of the Philippines is sometimes tamed, and by the courage it displays, shows that it is of the true game breed, and probably identical with the domesticated bird. This is what the authors of the Spanish Geographical Dictionary say of it in their introduction:—"In the woods there are beautiful wild cocks. These are very brave in the combat and always come off victors with the large but cowardly cocks of China, and not with these alone, for they will contend with the famous gallant band of the Laguna." Most of the advanced nations of the Asiatic Islands are gamblers, and the favourite shape which gaming takes with them is cock-fighting. This includes the people of Bali, Lamboc, Celebes and all the Philippine islands, the only material exception being the Javanese. The passion for cock-fighting is impressed on the very language of the Malays. Thus there is a specific name for cock-fighting, one for the natural spur of the cock, and another for the artificial; two names for the comb, three for the crow, two for a cock-pit, and one for a professional cock-fighter. The passion is no where carried further than in the

Spanish dominions in the Philippines. There, it is licensed by the government, which derives from it a yearly revenue of about 40,000 dollars, or about £10,000.—*Crawfurd Dic. p.* 118.

(2752) COCKS-COMBS. These flowering plants are little better than weeds in Madras, unless planted in well manured soil and watered with good water, they are not worth pot cultivation : raised from seeds in September and October.—*Jaffrey.*

(2753) COCOA. CACAO.

Cacao, Fr. | Cocao, It., Port., and Sp.
Kakao. Ger.

This has already been described at some length under the heads cacao and chocolate. The bruised seeds or nuts of the cacao, or chocolate tree (*Theobroma cacao*). The seeds or *nibs*, of which there are several varieties, more or less esteemed, are oval, about as large as an olive, and covered with a violet or ash-gray skin, which encloses two cotyledons of a fatty nature. When simply bruised, they constitute the cacao of the shops ; reduced to a paste, mixed with sugar, and flavoured with vanilla, cinnamon, &c. they become chocolate. The tree is a native of Mexico, but is extensively cultivated in the West India Islands.—*Faulkner.* At the Madras Exhibition of 1855 the Cocoa seeds sent by General Cullen from his gardens near Oodagherry, 1,800 feet above the sea, were the only samples ; they were of good quality, the beans being plump, ripe and clean, but small, not well cured and without colour. The jury considered them deserving of honorable mention. Considering how much of this article is employed daily in private life, it is of great consequence to get good Cocoa grown in India. The climate and soil of the Western coast would appear peculiarly favorable. For the cultivation of the tree, from which this valuable nut is produced, the Cocoa flourishes best in the alluvial soil of mountain vallies, though it will grow well at some elevation on mountain sides. Great care should be taken in the selection of plants, as the varieties are numerous, some producing very superior fruit to the others ; judgment on this point must chiefly be acquired by experience. Considerable diversity of opinion exists as to the distance at which the plants should be placed ; some authorities considering that from 12 to 16 feet apart is sufficient, others maintaining that 30 feet is not too much. It is clear that a free ventilation of air should be insured to the tree, after it has come to its full growth, and this cannot well be attained with a smaller space than 30 feet. The Cocoa plant requires large forest trees of favourable sorts to be scattered amongst them, to protect them—the e used for this purpose in the West-Indies and uth America is one of the Bombaceæ. The erage return of Cocoa per tree, when the trees planted close together, is from 1 to 3 lbs. re being two crops in the year, but as much from 9 to 16lbs may be procured by proper planting and cultivation. The plants begin to bear at from 5 to 7 years of age : during this period, the interspaces between the rows of trees can be rendered productive by planting Yams and Vegetables in them. Great care is required in curing the Cocoa, after it is separated from the pod, and on the method of fermenting and drying depends very much the production of a good or bad article.—*M. E. J. R.*

(2754) COCOS or EDDOES, Arum esculentum. The various species of Arum in Southern Asia, have already been noticed under that head, and our present observations are confined to one, very suitable for the food of man. This root has not hitherto been considered of sufficient importance to demand particular care in its cultivation, except by those who are engaged in agricultural pursuits, and derive their subsistence from the productions of the soil. But though the cultivation of the root is almost unknown to the higher classes in society, and little regarded by planters in the colonies, it is a most valuable article of consumption. Amongst the laboring population of the West Indies it is the principal dependance for a supply of food and it well merits to be more extensively cultivated than it now is, in Eastern and Southern Asia. Long droughts may disappoint the hopes of the yam crop, storms and blight may destroy the plantain walks, but neither dry for wet weather materially injure the coco ; it will always make some return, and though it may not afford a plentiful crop, it will yield a sufficiency until a supply can be had from other sources. For this reason the laborer in the West Indies always takes care to put in a good plant of cocos into his provision ground as a stand by, and knowing their value, is perhaps the only person who bestows any degree of care or attention upon them. Previous to their emancipation, whole families of negroes lived upon the produce of one provision ground, and the coco formed the main article of their support. Where the soil is congenial to the white and black Bourbon coco, the labor of one industrious person once a fortnight will raise a supply sufficient for the consumption of a family of six or seven persons. The coco begins to bear after the first year, and with common care and cultivation the same plant ought to give annually two or three returns for several years. In Jamaica, a disease something similar to that affecting the potato, has been found injurious to the coco root. This disease, which has baffled all inquiry as to its origin, affects the plants in and after the second year of their being planted. The first institution of it is the change in the leaves, which gradually turn to a yellow hue, have a sickly appearance, and at length drop off at the surface of the earth. The stock or "coco head," as it is called, below ground, having become rotten, nothing but a soft pulpy mass remains. In some fields every third or fourth root is thus af-

fected, in others much greater numbers are destroyed, so much so that the field requires to be almost entirely replanted, by which not only an expense is entailed, but a heavy loss sustained, from the field being thrown out of its regular bearing. The black coco seems to suffer less than the white. Another species, the Taro (*Arum colocasia, Colocasia esculenta* and *macrorhizon*), is an important esculent root in the Polynesian islands. In the dry method of culture practised on the mountains of Hawaii, the roots are protected by a covering of fern leaves. The cultivation of taro is hardly a process of multiplication, for the crown of the root is perpetually replanted. As the plant endures for a series of years, the tuberous roots serve at some of the rocky groups as a security against famine. It is also extensively cultivated in Madeira and Zanzibar, and has even withstood the climate of New Zealand. It is grown also in Egypt, Syria, and some of the adjacent countries, for its esculent roots. A species is cultivated in the Deccan, for the sake of the leaves, which form a substitute for spinach. Farina is obtained from the root of *Arum Rumphii* in Polynesia.—*Simmonds, p.* 364.

The Cocoa-nut Palm, little if at all known to the Ancients, was particularly noticed by the Arabs, being by them called *Jouz hindee* or Indian nut; but at much earlier periods, in Sanscrit works, by the name of Nari- and Nali-kera. It is, no doubt, the "great nut of India," which Sir John Maundeville mentions among the trees of that country, as producing nuts as large as men's heads. In the East, where it is indigenous, it must from the earliest times have attracted the attention of the inhabitants. But it would be impossible in the present day to distinguish the trees which have been introduced from those which are now growing apparently wild, on the various tropical coasts and islands where they are found in such vast abundance. As, for instance, in the Maldive and the Laccadive Islands; also, on the Malabar coast and in Ceylon, as well as on the eastern side of the Bay of Bengal, whence it ascends both the Burrampooter and Ganges Rivers to considerable distances. Likewise, in most of the islands of the great Archipelago forming the *India aquosa* of old authors, from the Sunda Isles to Molucca, and in those of the Pacific Ocean. It is, moreover, cultivated in various tropical parts of the New World. The Cocoa-nut (*Cocos nucifera*) and the Oil Palm (*Elæis guineenis*) have been remarked by a distinguished botanist, Mr. Brown, as the only two of their group (*Cocoinæ*) found in the Old World. The Cocoa-nut Palm is one of the great ornaments of the shores of tropical countries. The cylindrical stems, with a diameter of about two feet, attain an elevation of from sixty to one hundred feet, and are surmounted with their crowns of numerous, wavy, and which, from their appearance may almost be said to be, feathery leaves. These are by botanists often called fronds, and by travellers their footstalks are often called branches. They are gigantic in size, being about twenty feet in length, with a strong, tough stalk, which forms the midrip, and has a number of narrow and long leaflets ranged along the two sides. The fruit is borne in bunches, of which there are from eight to twelve, each bearing, on trees growing in favorable situations, from five to fifteen nuts, so that each tree may produce from eighty to one hundred nuts annually. Mr. Bennett has well observed that the tough and thick (and it may be added, light) covering of the nut protects the germ while it floats even on salt water, and it is thus borne to barren spots, where it germinates, and causes even the smallest islets, just appearing above water, to become covered with clumps of Cocoa-nuts, as the fruit falling springs up and forms young trees around the original tree. Thus the Cocoa-nut is found on barren, uninhabited islands, as well as in populous districts; and though it attains the greatest perfection on the coast, it may yet be seen at considerable distances in the interior, and even at some elevation, as 800 feet in Ceylon. The Singalese have a saying, that the Cocoa-nut trees only flourish where you can walk and talk among them. This evidently

means that the trees must not be planted too close together; nor should any undershrubs be allowed to grow about their roots. The Laccadive Islands are famed for the good quality of the coir which is made there and exported to the Malabar coast. The cocoa-nut tree is almost the sole object of culture and the chief means of subsistence, each person consuming about four nuts per diem. The principal inhabitants generally own considerable numbers of trees, and the custom prevails of marking trees with certain house marks, in the same way that sheep are marked in other countries. Taxes are levied on these trees, according to immemorial usage; and mortgages are secured on them at the rate of one rupee per tree of good quality. The soil and climate of these islands is so well adapted to the cocoa-nut, that they require to be looked after only for the first year; after which they are transplanted, and watered for a few weeks, until they take root, when they are left entirely to themselves, and come into bearing at periods varying from eight to twenty years, and will continue to bear for seventy or eighty years. In the island of Kiltan, it is said that a nut buried with a knife will grow, requires no attention, and comes into bearing early. The tree is not so large and strong as that of the coast, and the nut about two thirds of the size only, and rounder in shape. The husk is smaller and less woody, and the fibre finer and more delicate, but stronger than that of the coast nut. The nut is also said to be more compact and oily, and to keep better than the coast nut, although, for the sake of the coir, the nut is cut before being quite ripe. Many of the trees are cut for their sap, there called *neara*, which the islanders drink in its unfermented state. The juice is drawn frequently, and fermentation checked by the addition of lime or chunam. "They are still so strict in the abstinence from all fermented liquors, that the manufacture of toddy would not be tolerated in the islands." (Robinson on 'Laccadives,' 1846.) Of the extent of the cultivation, we are informed that in the islands under British protection—that is, in Amendeevy, Kadamat, Kiltan, and Chetlat, containing in 1844 a total population of 3609—there were 122,153 Cocoa-nut trees. Of these, 8129 were chouk or unproductive, 45,070 young trees, and plants, and 69,254 were fully productive. Of the abundance of the Cocoa-nut tree on the Malabar coast, we may form an idea from the description of the chief town, Cannanore; as the topes or clumps of Cocoa-nut are said "to be seen between the officers' houses, surrounding the cantonments in every direction, and extending in the distance as far as the eye can reach; and the cantonment may be said to be imbedded in a forest of these trees." But it is abundant everywhere, and in many places forms a belt along the whole coast. The majority of the houses on the Malabar coast are roofed with

Cadjan—that is, with the dried leaves of the Cocca-nut—which resist the rain better than tiles; but the roofs should be fresh thatched before the accession of the rainy season. The average produce of Cocoa-nuts in the whole of Malabar is estimated at from 300 to 400 millions annually, which are valued at half a million of rupees; but in addition to this, from 20,000 to 25,000 candies of Copra (or the dried kernels) are exported, valued at 400,000 rupees. The Cocoa-nut flourishes on the coasts of the southern provinces of the Indian peninsula, and succeeds on many parts of the western coast of the Bay of Bengal, as well as in the southern parts of that province. It also succeeds well on the eastern coasts of that bay, though the cultivation has not been carried on in the former Burmese territories to the extent of which the coasts are susceptible, nor even to the degree which the people require for their own consumption, as considerable quantities have long been imported from the Nicobar Islands. The trees are said to begin to produce fruit in the eighth, and to be in full bearing in the twelfth year after planting, and yield from eighty to a hundred nuts annually. But this is probably above the average. Mr. Baumgarten, in a paper on the agriculture of Malacca ('Journ. Indian Archipelago,' iii, p. 710), while considering what kinds of cultivation are most inviting, states that those of an indigenous kind claim a preference, such as the Cocoa-nut, Betel-nut, Sago, and Kabong, with the usual variety of fruit trees found in the Dusans of Malacca. All these are Palms; and of them, *Cocos nucifera* and *Areca Catechu* are no doubt the first two. The Sago tree is probably *Sagus lævis*, and the Kabong, *Arenga saccharifera*. He further states, that, "Supposing a planter purposes opening a Cocoa-nut plantation, he should choose a gently sloping or level surface, with a portion of swampy land in its vicinity for a paddy-field for food for the labourers." "The Malays," he says, "bestow little care on their Cocoa-nut gardens. The Cocoa-nut there begins to bear at the end of the seventh year, but full crops cannot be expected until the ninth year, During this interval the utmost average quantity that can be expected will not exceed twenty-five nuts annually. But the fruit-bearing power of the trees may be considerably improved by extracting toddy from the blossom-shoots for the manufacture of jaggery, during the first two years of its productiveness; after which it may be discontinued. The subsequent annual produce may be safely reckoned at fifty nuts per annum; and forty may be considered the average number obtained from trees that are crowded to within fifteen feet of each other. The Cocoa-nuts sell for about eleven dollars per thousand." Mr. Baumgarten also recommends, that during the first four or five years, Millets, Chillies, Kechong (pulse), Sweet

Potatoes, Yams, and Pumpkins, be cultivated in the intervals of the Cocoa-nut plantation. Dr. Buchanan, in his journey across Mysore and down to the Malabar coast, in 1803, observes that in some places he found the green Cocoa-nuts sold for making ropes, at the rate of 2000 for about 8*d.*; but the husk of the ripe Cocoa-nut was not fit for the purpose (i, 156). These are commonly burnt for fuel (ii, 50). The green husks of the nuts which have been cut for their juice are steeped in water for six months. They then beat them on a stone with a stick, and rub off with their hands the rest of the adhering substance. The fibres, or Coir, are then fit to be twisted into yarns. In South Malabar (ii, 401), he says, a little bad Coir is made from the husks of the nuts that are used green in the country; a few of the nuts are exported with the husk on, but in general they are sent to the north inclosed in shell only. The Cocoa-nut tree is valued not only as applicable to many of the same purposes as other Palm trees, but for the sap procured by cutting the spathes, of the flower-stalks, which is either drank in its fresh state, boiled down to a coarse sugar or jaggery, or allowed to ferment into spirit and vinegar: The milk of the nuts also forms a wholesome drink, while the kernel is used as an article of diet or in cookery in its fresh state, or dried and exported by the name of Copra. In both states it is well known to abound in oil, which is used in the East for anointing the body, for the lamp, and for culinary purposes, and is now exported in such enormous quantities to Europe. The nut, besides, yields large quantities of a fibre which will be more especially the object of our attention. That the Cocoa-nut is one of the most valuable trees of tropical regions has long been known. It is therefore well worthy of cultivation in such situations as are suitable to it; as it abounds in products useful as articles of diet, as well as for commerce and manufactures.—*Royle Fib. Plants.* Though the common Cocoa-Nut Palm, is found all over the tropical parts of the world, especially in the vicinity of the sea, growing within reach of salt-water, and establishing itself upon reefs and sandbanks as soon as they emerge from the ocean, nevertheless its principal range is said by Mr. Marshall to be between the equator and the 25th parallel of latitude, and in the equinoctial zone, to an altitude of about 2900 feet. Its great importance to man has caused it to be cultivated wherever the climate is favourable to its growth; and accordingly it is sometimes found occupying extensive tracts to the exclusion of all other trees: the whole Brazilian coast from the river San Francisco to the bar of Mamanguape, a distance of 280 miles, is, with few breaks, thus occupied; and it was estimated that in the year 1813 no fewer than 10,000,000 trees were growing on the south-west coast of Ceylon.—*Eng. Cyc. p.* 54. This palm is one of the most useful

of the extensive family to which it belongs, supplying food, clothing, materials for houses, utensils of various kinds, rope and oil; and some of its products, particularly the two last, form important articles of commerce. An old writer, in a curious discourse on palm trees, read before the Royal Society, in 1688, says, "The coco-nut palm is alone sufficient to build, rig, and freight a ship with bread, wine, water, oil, vinegar, sugar, and other commodities. I have sailed (he adds) in vessels where the bottom and the whole cargo hath been from the munificence of this palm tree. I will take upon me to make good what I have asserted." And then he proceeds to describe and enumerate each product. Another recent popular writer speaks in eloquent terms of the estimation in which it is held, and the various uses to which it is applied. "Its very aspect is imposing. Asserting its supremacy by an erect and lofty bearing, it may be said to compare with other trees, as man with inferior creatures The blessings it confers are incalculable. Year after year the islander reposes beneath its shade, both eating and drinking of its fruit: he thatches his hut with its boughs, and weaves them into baskets to carry his food; he cools himself with a fan plaited from the young leaflets, and shields his head from the sun by a bonnet of the leaves: sometimes he clothes himself with a cloth like substance which wraps round the base of the stalks, whose elastic rods, strung with filberts, are used as a taper. The larger nuts, thinned and polished, furnish him with a beautiful goblet; the smaller ones with bowls for his pipes; the dry husks kindle his fires; their fibres are twisted into fishing-lines and cords for his canoes. He heals his wounds with a balsam compounded from the juice of the nut; and with the oil extracted from its pulp embalms the bodies of the dead. The noble trunk itself is far from being valueless. Sawn into posts, it upholds the islander's dwelling; converted into charcoal, it cooks his food; and, supported on blocks of stone rails in his lands. He impels his canoe through the water with a paddle of the wood, and goes to battle with clubs and spears of the same hard material. In Pagan Tahiti, a cocoa-nut branch was the symbol of regal authority. Laid upon the sacrifice in the temple, it made the offering sacred; and with it the priests chastised and put to flight the evil spirits which assailed them. The supreme majesty of Oro, the great god of their mythology, was declared in the cocoa-nut log from which his image was rudely carved. Upon one of the Tonga Islands there stands a living tree, revered itself as a deity. Even upon the Sandwich Islands the coco palm retains all its ancient reputation; the people there having thought of adopting it as the national emblem." Besides the foregoing and following uses, I am aware of several scents and spirituous liquors being procur- from the flowers and pulp of the coco-nut. This

palm tree is one of the finest objects in nature. Its stem is tall and slender, without a branch; and at the top are seen from ten to two hundred coco-nuts, each as large as a man's head; over these are the graceful plumes, with their green gloss, and beautiful fronds of the nodding leaves. Nothing can exceed the graceful majesty of these intertropical fruit trees, except the various useful purposes to which the tree, the leaf, and the nut are applied by the natives.

1. The stem is used for—bridges, posts, beams, rafters, paling, ramparts, loop-holes, walking sticks, water butts, bags (the upper cuticle), sieves in use for arrowroot

2. The coco-nut is used for—milk, a delicious drink; meat from the scraped nut, for various kinds of food; jelly, *kcra*, pulp, nut, oil, excellent and various food for man, beast, and fowl. The shell for vessels to drink out of, water pitchers, lamps, funnels, fuel, *panga* (for a game). The fibre for sinnet, various cordage, bed stuffing, thread for tying, combs, scrubbing-brushes, girdle (ornamental), whisk for flies, medicines, various and useful.

3. The leaf is used for—thatch for houses, lining for houses, *takapau* (mats), baskets (fancy and plain), fans, *palalafa* (tor sham fights), combs (very various), bedding (white fibre), *tafi* (brooms). *kubatse* (used in printing), *mama* (candles), screen for bedroom, waiter's tray. Here are no less than forty-three uses of which we know something; the natives know of others to which they can apply this single instance of the bounty of the God of the nature. For house and clothes, for food and medicine, the coco-nut palm is their sheet anchor, as well as their ornament and amusement, who dwell in the torrid zone.—*Simmonds' Com. Products.* In hot countries indeed the uses to which the Cocoa-nut tree is applicable are innumerable. The roots are chewed in place of the areca-nut; gutters, drums, and the posts of huts are formed from the trunk; the young buds are a delicate vegetable; shade is furnished by the leaves when growing, and after separation from the tree their large size and hard texture render them invaluable as thatch for cottages; they are moreover manufactured into baskets, buckets, lanterns, articles of head-dress, and even books, upon which writing is traced with an iron stylus. Their ashes yield potash in abundance; their midrib forms oars; and brushes are formed by bruising the end of a leaf with a portion of the midrib adhering to it. The sap of the tree during the time of blossoming ascends in large quantities: it is very sweet, and flows freely on the stem being punctured. In Ceylon it is daily collected by a class of people known as 'toddy-drawers', who get up early to procure it for the use of the inhabitants. If allowed to stand, this toddy ferments, and forms palm-wine, from which an ardent spirit called arrack is distilled. By further distillation sugar is procured from this spirit, which is called 'jaggery sugar.' This sugar, mixed with lime, forms a powerful cement, which resists moisture, endures great solar heat, and will take a fine polish. A farinaceous matter contained in the stem is a good substitute for sago. The ripe fruit is a wholesome food, and the milk it contains is a grateful, cooling beverage; indeed these together form the principal sustenance of the poor Indians in many countries. The nuts are inclosed in an outer husk, which has three flat sides terminating at the top in a blunt point. This peculiar form seems to be a special provision for the dissemination of the species; growing, as it does, near the shores of seas and rivers, its large seeds drop into the water, and their shape particularly adapts them for sailing; one edge, being downwards, forms the keel, while the upper surface being flat, is acted upon by the wind, and so propelled along on the surface until it reaches some coral reef or shore, where, when stranded, it vegetates and rises to be a magnificent palm, affording food and shelter in abundance. The shell of the Cocoa-nut is enclosed in a fibrous husk, which has now become a considerable article of commerce on account of the strength and durability of the fibre. Its preparation is very simple, consisting of little more than beating the husks to separate the fibres, which are dry and but loosely held together, and afterwards drawing them through a coarse comb or heckle, by which the refuse is cleaned out; it is then spun into yarns of different thickness, and is now extensively manufactured in Europe into ropes and matting: it is also used to stuff mattrasses and cushions. In India it is very generally used as cordage for vessels, and for fishing-nets; its lightness recommends it specially for the latter purpose. Its durability is surprising; perhaps no other vegetable-fibre will resist so long the action of alternate dryness and moisture. The hair-like fibre is made also into scrubbing-brushes; and the poorer classes in many places use the entire husk for the same purpose. The imports of cocoa-nut yarn and rope into England are greatly increasing: in the year 1851 (as nearly as can be ascertained) 10,661 tons were brought into Liverpool from Ceylon and Bombay. The oil of the Cocoa-nut is valuable as an export: it is used largely in Europe for burning, in the manufacture of torches, and in the composition of pharmaceutical preparations. Mixed with dammer (the resin of shorea robusta), it forms the substance used in India for paving the seams of boats and ships.—*Eng. Cyc. page* 54. The celebrated Rumphius has given a very elaborate account of the Cocoa-nut Palm, and of its uses, under the name of *Palma indica major*, or Calappa, in his 'Herb. Amboin.,' i, pp. 1—25, Mr. G. Bennett, in his 'Wanderings,' has also given a very interesting

account of it (vol. ii, p. 295): as also Mr. Robinson, of the Madras Civil Service, in his 'Report on the Laccadive Islands,' published in the 'Madras Literary and Scientific Journal.' From these sources we condense the following notice of the useful products of this "Prince of Palms." See also the 'Wernerian Trans.,' vol. v, for a full account of the uses of this tree; as also Mr. Marshall, in his 'Natural and Economical History of the Cocoa-nut,' 1832. The Cocoa-nut, valued as it is in its ripe state, is probably, in the countries where it is indigenous, most used as an article of diet in its young or green state. It then affords both solid food and a pleasant drink, because it contains an abundance of the fluid, which Mr. G. Bennett says is beautifully clear, and has a sweetness, with a slight degree of astringency, which renders it a very agreeable beverage. Mr. Bennett mentions that in Ceylon, house-plasterers use the water of the green Cocoa-nut as an ingredient in their white-washes, made of pure lime. It is a general practice of the natives of India to add some vegetable matter to their cements. This he always found cooling and refreshing in all his excursions in intertropical countries. The pulp of the young nut is delicate, easily removed with a spoon, and may very well be named a vegetable blancmange. The ripe fruit is also eaten, but it is more frequently employed in cookery; the grated kernel being placed in a cloth, water is poured on it, a white juice is extracted by pressure, which, Mr. Bennett says, "may with propriety be termed 'Cocoa-nut milk.' It is used either with or without the grated kernel in their various curries and muligatawnies." Besides these edible parts, the heart, or the very young leaves of this Palm, as well as of some others, is called the *cabbage*, and, according to all accounts, forms "an excellent vegetable, either cooked or dressed in stews, hashes, or ragouts." The beverage known to Europeans as toddy or palm wine, is obtained from the flower-spathes, before the flowers have yet expanded. These are themselves astringent, and used medicinally. To procure the toddy, the spathe is first tied with the young leaves, and is then cut a little transversely from the top, and beaten either with the handle of the toddy-knife or with a piece of hard wood. After some days, an earthen chatty or vessel, or a calabash, is hung to the spathe, so as to receive the toddy as it exudes. This is collected every morning and evening; the spathe being cut a little every day. If this palm wine is drawn early in the morning, it forms a pleasant drink. But fermentation takes place in the liquor a few hours after it has been collected, and it is then used by the bakers as yeast. The fermented liquor or toddy is much drank by the natives; at other times the spirit is distilled from it, and forms one of the kinds of arrack or *ark* that is, spirit. One hundred gallons of toddy produce by distillation, it is said, twenty-five of arrack. Or it may be allowed to undergo the acetous fermentation and produce very good vinegar. Or instead of being allowed to ferment, the toddy may be made to yield *jaggery* or sugar. For this purpose, a supply of sweet toddy is procured mornings and evenings, particular care being taken that the vessels employed have been well cleaned and dried. Eight gallons of sweet toddy, boiled over a slow fire, yield two gallons of a lusciously sweet liquid, which is called *jaggery* or *sugar-water*; which quantity being again boiled, the coarse brown sugar called jaggery is produced. The lumps of this are separately tied up in dried banana leaves. Cocoa-nut oil is one of the best-known products of this Palm, from its extensive employment in Europe especially for making the excellent candles known as Stearine. In the East, it is employed as a lamp-oil, and for anointing the body, especially after it has been rendered fragrant by mixture with such aromatic oils as those of sandal wood and of jessamine. The oil is obtained by first removing the kernel from the shell, which is boiled in water for a short period; it is then pounded in a large mortar, taken out, and pressed. The milk, as it is called, is then boiled over a slow fire, when the oil floats on the top, which being skimmed off, is afterwards boiled by itself. Two quarts of oil, it is said, may be procured from fourteen or fifteen Cocoa-nuts. "The Malabar method of extracting the oil, is by dividing the kernel into two equal parts, which are ranged on shelves made of laths of the Areca Palm or of split bamboo, spaces being left between each lath of half an inch in width; under them a charcoal fire is then made, and kept up for about two or three days, in order to dry them. After this process they are exposed to the sun on mats, and when throughly dried (then called Koppera or Copra), are placed in an oil-press, or siccour." These form articles of export to Bombay and elsewhere. Cocoa-nut oil is liquid at the ordinary temperature of the countries where it is produced, but becomes solid at lower temperatures, as about 70°, and has a specific gravity of 892. It is one of the fixed or fatty oils, of which such large quantities are now imported into this country, and, like them, consists of both solid and fluid constituents; the latter, or Oleine, being separated by pressure from the solid parts called Stearine. The solid fat of the Cocoa-nut is by others distinguished by the name of Cocein, which has been so largely employed in making Stearine candles, but which, from the chemical changes taking place in the process, are now called Stearic, and which are made in such enormous quantities and of such excellent quality under Mr. G. Wilson's intelligent superintendence at Belmont, Vauxhall. In consequence of this increased demand, and the facilities afforded by the establishment of a Go-

vernment steam-engine at Colombo for separating the oil with greater facility, as well as to the duty having been taken off, we may account for the great increase in the importation of this oil. Cocoa-nut oil was sent to the Exhibition of 1851, from different parts of the Madras territories, and of very fine quality, by Messrs. Sainte, of Cossipore—for these a Prize Medal was awarded. The refuse or oil-cake is stated to be excellent food for fattening pigs and poultry. The imports, which were in 1838, 32,666 cwt., had risen to 85,463 cwt. in 1848, and have since continued to increase.

	Cwt.		Cwt.
1848 - - -	85,463	1851 - - -	55,915

Cocoa-nuts, from the quantity of fibre on their exterior and oil in their interior, are necessarily well suited for burning. Hence they are sometimes fixed on stakes, and used to illuminate roads, &c. The shell itself, when burnt, yields an excellent kind of charcoal. In their entire state they are used for a variety of purposes, such as hooqas, vessels to hold water, cups to drink out of; and with handles fixed into them, they serve as ladles and spoons. We sometimes see them brought home as curiosities, highly polished on the outside; sometimes scraped so thin as to be semitransparent; at other times, stained black, elaborately carved, and mounted in silver. Flowers and ornaments are made from the Cocoa-nut fruit dried, and are meant to represent the garlands given to visitors of distinction on visits to the palace. They are worn by Tanjore ladies at a particular festival. Besides these various products, the wood of the Cocoa-nut tree, one of the Porcupine woods of commerce, is used for various purposes, as among the Singalese, when it has become old and the tree has ceased to bear, for making small boats, frames for houses, rafters, &c.; also for spear-handles, furniture, and fancy articles of different kinds. It is also exported to European markets, where it is known by the name of *porcupine wood*. The Singalese split the fronds in halves, and plait the leaflets neatly, so as to make excellent baskets, and, under the name of *cadjans*, they form the usual covering of their huts, as well as of the bungalows of Europeans; and are exported to northern parts, where the Cocoa-nut does not flourish so well: 149,500 were imported into Bombay in the year 1850-51. The dried fronds are sometimes used as torches or for fuel; their midribs, tied together, are sometimes used as brooms for the decks of ships, as the fibres of the stalk are woody, brittle, and difficult to clean. The leaves are also in other places plaited into baskets; and combs are said by Mr. Bennett to be made of the midrib of the leaflets in the Friendly Islands. In the Laccadive Islands mats are made of the Cocoa-nut leaf, cut out of the heart of the tree just before the unfolding of the leaf, though this involves the loss of the bunch of fruit which comes out with each leaf. It is probable that the leaves of the *chouk* or unproductive trees are chiefly employed. These mats are, however, of fine quality, and much esteemed when exported. In this Island they are employed for the sails of the smaller boats.—*Royle Fib. Plants.*

This fine palm, which always forms a prominent feature in tropical scenery, is a native of Southern Asia, but it is cultivated nowhere so abundantly as in the Island of Ceylon, and those of Sumatra, Java, &c. On the shores of the Red Sea it advances to Mokha, according to Niebuhr; but it does not succeed in Egypt. It is cultivated in the lower and southern portions of the Asiatic Continent, as on the coasts of Coromandel and Malabar, and around Calcutta. In the island of Ceylon, where the fruit of this tree forms one of the principal aliments of the natives, the nuts are produced in such quantities that in one year about three millions were exported, besides the manufactured produce in oil, &c. According to Marshall it requires a mean temperature of 72 deg. Its northern limit, therefore, is nearly the same as the southern limit of our cereals. Rumphius enumerates thirteen varieties of this palm, but many of these have now been placed under other genera, and Lindley resolves them into three species—*C. nucifera*, the most generally diffused species, a native of the East Indies; and *C. flexuosa* and *plumosa*, natives of Brazil. The trunk, which is supported by numerous small fibrous roots, rises gracefully, with a slight inclination, from forty to sixty feet in height; it is cylindrical, of middling size, marked from the root upwards with unequal circles or rings, and is crowned by a graceful head of large leaves. The terminal bud of this palm, as well as that of the cabbage palm (*Euterpe montana*), is used as a culinary vegetable. The wood of the tree is known by the name of porcupine wood. It is light and spongy, and, therefore, cannot be advantageously employed in the construction of ships or solid edifices, though it is used in building huts; vessels made of it are fragile and of little duration. Its fruit, at different seasons, is in much request; when young, it is filled with a clear, somewhat sweet, and cooling fluid, which is equally refreshing to the native and the traveller. When the nut becomes old, or attains its full maturity, the fluid disappears, and the hollow is filled by a sort of almond, which is the germinating organ. This pulp or kernel,

when cut in pieces and dried in the sun, is called copperah, and is used in curries throughout Eastern and Southern Asia; and from it a valuable species of oil is expressed, which is in great demand for a variety of purposes. The refuse oil cake is called Poonac, and forms an excellent manure. A calcareous concretion is sometimes found in the centre of the nut, to which peculiar virtues have been attributed. The most favorable situation for the growth of the coco palm is the ground near the sea-coast, and if the roots reach the mud or salt water, they thrive all the better for it. The coco-nut walks are the real estates of India, as the vineyards and olive groves are of Europe. I have seen these palms growing well in inland situations, remote from the sea, but always on plains, never upon hills or very exposed situations, where they do not arrive to maturity, wanting shelter, and being shaken too violently by the wind. The stems being tall and slight, and the whole weight of leaves and fruit at the head, they may not unaptly be compared to the mast of a ship with round top and topmast without shrouds to support it. Ashes and fish are good manures for it. The coco-nut is essentially a maritime plant, and is always one of the first to make its appearance on coral and other new islands in tropical seas, the nut being floated to them, and rather benefiting than otherwise by its immersion in the salt water. Silex and soda are the two principal salts which the coco-nut abstracts from the soil, and hence, where these do not exist in great abundance, the tree does not thrive well. Salt is very generally applied to the coco nut when planted. Far in the interior of Brazil Dr. Gardner states, he has seen as much as half a bushel applied to a single tree, and that too when it cost about 2s. a pound, from the great distance it had to be brought. That the application, therefore, of salt, of seaweed, and saline mud, does more than supply soda, must be very evident, if we only recollect how difficult it is to dry any part of our dress that has been soaked in salt water, and what effect damp weather has on table salt, which, in a balance, has often been made use of as an hydrometer. Moisture is always attracted by salt, and the more sea mud and other such little matters that coco-nut planters can apply round the roots of their trees, there will most assuredly be the less occasion for watering them in the dry season. Sea weed contains but very little fibrous matter, being chiefly composed of mucilage and water; and the experiments of Sir J. Pringle and Mr. C. W. Johnson, prove that salt in small quantities assists the decomposition of both animal and vegetable substances. Decomposed poonac, or oil-cake, is one of the best manures that can be applied, as it returns to the soil the component parts of which it has been deprived to form the fruit. The primary direction of the planter's industry will be to the establishment of a nursery of young plants. In Ceylon, for this purpose, the nuts are placed in squares of 400, covered with one inch of sand, or salt mud; are watered daily till the young shoots appear, and are planted out after the rains in September. Sand and salt mud are to be found on almost all the coasts where it would be desirable to plant nuts, and if they are put into the ground at the commencement of the rainy season, artificial watering will scarcely be necessary. Any period, when there are showers, would answer for transplanting them. I should say from the middle to the end of January would be best, when they are placed in the nursery in October and November; and in October when they are planted in June. It is said that they should be allowed from 20 to 30 feet space apart, but I will calculate their return when planted 27 feet apart every way. This will give 51 coco-nut trees per acre. If manured, for the first two years, with seaweed and salt mud, and supplied with water in dry weather, there need be no loss, and the plants will thrive the better. The land must be kept clear of weeds till the plants are matured, in order to permit them abundance of air and light. In five years, when well cared for, the flower may be expected, but the plants, will not be in full bearing before the seventh or eighth year. From 50 to 80 nuts are the annual crop of a tree; but I will calculate at the lowest rate. One hundred nuts will yield, when the oil is properly expressed, at least two gallons and a half. I shall not take into account the making of jaggery sugar and toddy, or spirit from the sap, as I do not consider that the manufacture would be remunerative; and it must be attended with much trouble, besides requiring a great deal of care and some skill. Take the case now of a plantation of 100 acres in extent. This would give us 5,800 trees, which, at 50 nuts per tree, 290,000 nuts, at 2½ gallons of oil per hundred would yield 7,250 gallons of oil, the value of which any person may calculate, but which, at the low rate of 3s. over charges, would furnish, as the gross plantation return in oil, a sum of £1,087 10s. sterling. If the cultivator, instead of making his produce into oil, were to sell it in its natural state, his gross return in the West Indies would be nearly £600 sterling, at the rate of ten dollars per thousand. Either of these sums would be a handsome return from 100 acres of any land, *requiring no cultivation or care whatever, after the fourth year and yielding* the same amount for upwards of half a century! But this is not all. An outlay of a few pounds will secure other advantages, and ought to enable the owner of a coco-nut plantation to turn his gross receipts for oil into nett profits. The coir made from the husk of the nut is calculated to realise nearly one-fourth of the proceeds of the oil, but if we put it down at one-fifth, we shall have, in addition to the value of the oil, £217 10s., thus

making a total of £1,305 sterling. If we obtained 60 nuts from each tree, the return would be £1,566 sterling, and if 75, £1,957, 8s. sterling: and this from 100 acres of sea side sand! But even *this* does not exhibit the whole return of this article of culture. Each nut may be calculated to give a quarter of a pound of poonac or oil-cake, being the refuse after expression, fit for feeding all kinds of stock, which may be estimated as worth £10 per ton. We must, therefore, add on this account to our first calculation, the sum of say £325; to the second, £390; and to the third, £485. This would give, in round numbers, the entire returns of the 100 acres planted:—At 50 nuts per tree, £1,630; at 60 ditto, £1,957; at 75, ditto, £2,446. These are striking results, and may appear exaggerated; but I will, to show how very moderate has been my calculation, give two returns, with which I have been favored from Ceylon. These, it will be seen, differ materially, but the latter I can rely on as a practical result, from a plantation in Jaffna, the peninsula of the northern portion of the island. After estimating the expense of establishing the plantation, the first writer sets down his return thus:—"The produce, calculating 90 trees to an acre, and 75 nuts to a tree, sold at £2 per 1,000, would yield 675,000 nuts, worth £1,350; or if converted into oil, calculating 30 to give one gallon, it would produce 22,500 gallons, or about 90 tons from 100 acres." From Jaffna, the following is an abridged estimate of return of 100 acres in full bearing:—"At 27 feet apart, 58 trees per acre, 5,800 trees, at 60 nuts per tree, 3,480 nuts per acre, 100 acres, 348,000 nuts, at 40 nuts per imperial gallon, 8,700 gallons of oil, at 2s. per gallon, netted £8 14s. per acre. The poonac left will pay the expense of making the oil. If shipped to England, at the present time (close of 1848), the selling price there being 55s. per cwt., measuring 12 imperial gallons, say, 4s. 7d. per gallon, and the cost and charges of sending it home and selling it being 23s., it would leave 3s. per gallon, or £13 per acre." This sum is *nett proceeds*. It will be seen by the above, that I have been extremely moderate in my computation of the return which may be anticipated, for there is no doubt that planters can, in favorable localities on the coasts of most of our colonies, cultivate this palm with as much success as attends its culture in Ceylon. By the first of the calculations I have cited from that island, the gross return appears thus:—

22,500 gallons at 4s 7d.	£5,156	5
Coir—one-fifth of value,... ...	1,031	4
Cake from 675,000 nuts, say ¼lb. each, 75 tons at £10.	750	0
Total gross return from 100 acres.	6,937	9

According to the other calculation, the return will stand thus:—

8,700 gallons at 4s. 7d.	£1,993	15
Coir...	398	15
Cake from 348,000 nuts, 34 tons..	340	0
Total gross return from 100 acres.	2,732	10

It will be seen that in my calculation I have set down the return lower than it is rendered in the less favorable statement from Ceylon by a sum of upwards of £1,000 sterling. But even supposing *one-half* of the amount of the lower Ceylon estimate could be realised, we should have a return of £1,366 5s. sterling from 100 acres of sea side sand. I now proceed to point out the very small outlay required to obtain these results. In places where the Cocoa-nut would be grown, there is generally no heavy woodland requiring great labor with axe and fire, and consequently one able-bodied man should get through the felling and clearing away bush, on an acre of the land to be prepared for the plant, in a short period,—say, on an average, four days. I will calculate, that for wages and rations, each hand employed will cost sixteen dollars per month, an outside price. Let us then say that ten laborers shall be at work. They fell two acres and a half per diem. In one month there should be nearly 70 acres felled; but I will say that the 100 acres will occupy them two months in felling and stacking the wood. During this period our planter may be considered to have had the aid of two more hands, engaged in the preparation, planting out, and care of the nursery of young plants. Two more hands must also be occupied in the construction of tanks and sheds, except where there is a stream of fresh water. For grubbing up the roots, if not very large size, the assistance of about a dozen cattle would be required, a labor which would be performed by means of the common grubbing machine, an implement in the form of a claw. We will consider that all hands are occupied another month in this manner, and in removing and re-stacking the wood, and turning up the land. The planting out would require but little time and labor. At the end of three months then, one-half of the hands, besides those engaged in the nursery and tanks, might be discharged. We must make an allowance for provision for the fodder of the cattle. Six thousand nuts would be required. Let us now see what are the planter's expenses; making ample allowance on account of each item:—

	dollars.
6,000 picked nuts at 10 dollars per 1,000,	60
Hire and rations of 12 hands, at 16 dollars, for 8 months, ..	576
Two hands at nursery, for same period,	96
Purchase of 12 cattle at 20 dollars,	240
Foddering cattle one month,	32
Hire of two extra hands, making tanks and sheds, 3 months,	96
Hire of 6 hands for 9 months,	864
Tools (including plough),	100
Total...	2,064

About £415 sterling for expenses for the first year. Where fencing is required, we must add

for making about three miles of fence, say £30 sterling. Two carts would also have to be provided, which will cost, say £20 more. In all we may compute the first year's expenditure at £460 sterling. Second year's expenditure: ploughing land, or hoeing it twice, watering plants, manuring, repairing fences, and supplying plants, say hire of eight men for six months, about £150 sterling. The same for the third. Fourth year's expenditure; hire of six hands for three months, cleaning land, and manuring plants, about £60 sterling, and the like, at the cultivator's option, for the fifth year.

Add for buildings,...	80

And we have a grand total of £960 sterling expended; for what purpose? To secure a net income of *at least* £1,200 sterling per annum for at least 50 years! In the first year's expenses many items might be cut down, but I leave the calculation as one to be considered by a party with small capital, intending to establish a Cocoa-nut plantation. I have allowed nothing for the cost of land, as it is impossible to compute that. In general it would cost next to the nothing mentioned. I have, by careful calculation, arrived at the conclusion that by combining the cultivation of provisions with the gradualbut steadily progressive establishment of a coco-nut plantation, any man of energy and perseverance may, with the aid of but four hands, clear, fence, and plant, in a favorable locality, 50 acres of coco-nuts within the year, yet have a balance in his pocket at its close. Such a person would, ere doing anything beyond putting in his nursery plants, establish a provision ground, of considerable extent, for the purpose of supplying himself and his laborers with bread kind, and vegetables, and of enabling him, by the disposal of the surplus produce in the market, to raise a sufficient sum of money to furnish the wages and rations of the men. I need not enter into a calculation to show how this could be done, as every one must be aware of an easy method of following out so simple a suggestion. Of course he would have to bear in mind that the provision ground is of secondary importance, and limit his exertion in that line accordingly; devoting to the coco-nut plantation the strictest daily attention. The cultivation of this tree deserves much more attention than has hitherto been paid to it, particularly in the East, where it not only forms part of the daily food of all classes of the community, but is an exportable article to neighbouring regions, the oil which

it yields having of late years become in great demand in England,for the manufacture of composite candles and soap, and there is no doubt of its continually extended application to such purposes. Supposing, nevertheless, the result of an increased cultivation of the coco-nut should be such as to cause a fall in price, and sink the nett return in England to 2s. per gallon; this being clear profit, would make this kind of plantation a safe and sure investment for both capital and labor in the Colonies. The coco-nut is usually planted as follows:—Selecting a suitable place, you drop into the ground a fully ripe nut, and leave it. In a few days a thin lance-like shoot forces itself through a minute hole in the shell, pierces the husk, and soon unfolds three pale green leaves in the air; while, originating in the same soft white sponge which now completely fills the nut, a pair of fibrous roots pushing away the stoppers which close two holes in an opposite direction, penetrate the shell, and strike vertically into the ground. A day or two more, and the shell and husk, which in the last and germinating stage of the nut are so hard that a knife will scarcely make any impression, spontaneously burst by some force within; and, henceforth, the hardy young plant thrives apace, and needing no culture, pruning, or attention of any sort, rapidly arrives at maturity. In four or five years it bears; in twice as many more it begins to lift its head among the groves, where, waxing strong, it flourishes for near a century. Thus, as some voyager has said, the man who but drops one of these nuts into the ground, may be said to confer a greater and more certain benefit upon himself and posterity, than many a life's toil in less genial climes. The fruitfulness of the tree is remarkable. As long as it lives it bears, and without intermission. Two hundred nuts, besides innumerable white blossoms of others, may be seen upon it at one time; and though a whole year is required to bring any one of them to the germinating point, no two, perhaps, are at one time in precisely the same stage of growth. Coco-nuts form a considerable article of export from many of the British colonies: 375,770 were exported from Honduras in 1844, and 254,000 in 1845; 105,107 were shipped from Demerara, in 1845; 3,500,000 from Ceylon in 1847. They are very abundant on the Maldive Islands, Siam, and on several parts of the coast of Brazil. Humboldt states, that on the south shores of the Gulf of Cariaco, nothing is to be seen but plantations of coco-nut trees, some of them containing nine or ten thousand trees. Ceylon is one of the localities where the greatest progress has been made in this species of culture. In 1832 several Europeans settled at Batticaloa, expressly for the purpose of cultivating this palm to a large extent. They planted cotton bushes between the young trees, which were found to ripen well, and nurse and shade

them. There are now an immense number of coco-nut topes, or walks, on the coasts of the island, and about 20,000 acres of land are under cultivation with this tree. The value of this product to Ceylon, may be estimated by the following return of its exports in 1847, besides the local consumption:—

	£
Declared value of nuts,.....	5,485
Ditto of Coir,.....	10,318
Kernels, or Copperah,..	6,503
Shells,...	210
Oil, ...	19,142
Arrack,.....	11,657
Total...	£53,315

The annually increasing consumption of the nuts holds out a great inducement to the native proprietors to reclaim all their hitherto unproductive land. The fruit commands a high price in the island, (ranging from ¾d. to 3d. per nut), owing to the constant demand for it as an article of food, by both Singhalese and Malabars; there is not so much, therefore, now converted into copperah for oil making. In the maritime provinces of the island, it has been estimated that the quantity of nuts used in each family, say of five persons, amounts to 100 nuts per month' or 1,000 per annum. It needs only a reduction in the cost of transit, to extend the consumption in the interior of the island to an almost unlimited extent. In 1842, Ceylon exported but 550 nuts, while in 1847 she shipped off to other quarters three millions and a half of nuts, valued at £5,500. The average value of the nuts exported may be set down at £7,000. In Cochin China the cultivation of the coco-nut tree is much attended to, and they export a large quantity of oil. At Malacca and Pinang it shares attention with the more profitable spices. Since the palm has been acclimatised in Bourbon, about 20,000 kilogrammes of oil have been produced annually. About 8,000 piculs of oil are exported annually from Java. A correspondent, under date December, 1849, has furnished me with the following particulars of coco-nut planting in Jaffna, the northern district of Ceylon, in which the culture has only recently been carried on; the facts and figures are interesting:—The Karandhai estate, the property of the late Mr. J. Byles, was sold last month for £2,400, part of it bearing. It consists of 303 acres, of which 229 are planted with coco-nuts—about half the trees six years old. The Victoria estate, in extent 170 acres, planted and part in bearing, and about seventy acres of jungle, was also sold for £1,500. Mr. G. Dalrymple was the purchaser of the latter, and Mr. Davidson of the former. Both lots were cheap. The properties are among the best in the district, the latter, especially, is a beautiful estate. About two-thirds of the estates planted are looking well, and the remainder but

COCOA-NUT PALM.

indifferently, in fact, ought never to have been planted, and I believe will never give any return. About 7,000 acres are now under cultivation here, and clearing is still going on. Estates can now be put in for about one half what they cost formerly, viz., about £4 or £5 per acre, and can be kept in order, inclusive of all charges, for about 15s. to 20s. per acre for the first two years, and about half that afterwards. Estates, in some instances, have been put in for about £3 per acre. Elephants have almost disappeared; now and then a stray one comes. Pigs are still a great nuisance, but the greatest anxiety among planters is regarding beetles. You will be sorry to hear that the first year the trees showed fruit or flowers, one-tenth of them were destroyed by the beetle; the insects still go on destroying, and hardly a tree attacked ever recovers. This is a very serious evil, and upon which the fortunes of those involved in coco-nut planting depend. The trees come into bearing but very slowly, and I consider no estate will give any return over its current expenses under twelve years. It takes twelve months from the formation of the flower, till the fruit ripens. On an estate, perhaps one of the oldest and best in this district, out of 120 acres, part seven and eight years old, about 12 per cent. are in flower or in bearing, and give a return of about twenty-four nuts per tree, on an average, yearly. On the next oldest, the return is not near so great. But few of the estates here will, I think, pay interest on the money laid out, and many will never pay anything over the expense of keeping them up, even after coming into bearing. I doubt if any estate in this district, however economically managed, will ever give a net return of more than £2, or perhaps of £2 10s. per acre, at least without there is a great increase in the consumption of oil in Europe. The consumption of this oil, in Europe, is under 5,000 tons. If the beetles do not destroy half the trees, the estates here when in bearing, if they yield anything, will give half that quantity; and it must be borne in mind that coco-nut oil is not a strong oil, like palm oil, and that soap boilers will never use it to any extent, for it will allow but little admixture of rosin, &c.; its use in Europe will be principally for candles and fancy soaps; but as by refining and compression they can now purify tallow, and make of it candles fully equal to those made from coco-nut oil, the consumption of the latter is not likely to increase. The consumption of candles is always limited on the continent of Europe, liquid oil being preferred, and in many instances gas is now being used where candles formerly were. The return of land planted with coco-nut trees in Ceylon, in 1851, was 22,500 acres; but this refers only to regular estates recently opened and cultivated chiefly by Europeans. Let us suppose that the natives possess besides, twenty millions.

of trees; Butolac in his time estimated the the number at thirteen millions. At 100 trees to the acre, twenty millions of trees give 100,000 acres, so that the total amount of land planted with cocoa nut trees would be 122,500 acres. An hydraulic press, for the manufacture of cocoa-nut oil, 1,200 horse power and weighing twenty-three tons, was cast at the Ceylon Iron Works, in 1850, by Messrs. Nelson and Son. In the island of Singapore there are now many extensive plantations in a very flourishing condition, holding out favorable prospects to the proprietors. Hitherto the island has been supplied almost wholly from abroad with nuts and oil for its consumption, which will, before long, be obtained exclusively from its own soil. In 1846 there were 10,000 coco-nut trees in bearing in Singapore. I have omitted to notice, in the foregoing observations, a very mistaken notion which prevails in many quarters, that it is best to let the trees drop their fruit, and not to pick the nuts when ripe. Nature directs differently. As soon as the husk of the nut is more brown than green it should be picked. It then makes better oil and better coir, than when left to shrivel up and fall from the tree. Colonel Low, in his "Dissertation on Pinang," gives some interesting details and statistics on coco-nut planting:—On a rough estimate—for an actual enumeration has not been lately taken—the total number of *bearing trees* in Pinang may be stated at 50,000, and those in Province Wellesley at 20,000; but very large accessions to these numbers have of late years been made. The tree is partial to a sandy soil in the vicinity of the sea, and Province Wellesley offers, therefore, greater facilities, perhaps, for its cultivation, than Pinang does, as its line of clear beach is longer, and has many narrow slips of light or sandy land lying betwixt the alluvial flats inland. There are several kinds of this tree known here; one has a yellowish color, observable both on the branches and unripe fruit; its branches do not droop much. A second has green spreading branches, more drooping than the former, the fruit being green colored until ripe; this is, perhaps, the most prolific; it also bears the soonest, if we except the dwarf cocoanut, which fruits at the second or third year, before the stem has got above one foot high. This last kind was brought from Malacca; it attains in time to the height of the common sort Its fruit is small and round, and of course less valuable than the other sorts. There is also a cocoanut so saturated with green, that the oil expressed from its kernel partakes of that color. It is a mistaken supposition that the coco-nut tree will flourish without care being taken of it. The idea has been induced by the luxuriant state of trees in close proximity to houses and villages, and in small coves where its roots are washed by the sea. In such circumstances, a tree, from being kept clear about the roots, from being

COCOA-NUT PALM.

shaded, and from occasional stimuli, advances rapidly to perfection; but in an extended plantation, a regular and not inexpensive system of culture must be followed to ensure success. The nuts being selected, when perfectly ripe, from middle-aged trees of the best sort, are to be laid on the ground under shades, and after the roots and middle shoots, with two branches, have appeared, the sooner they are planted the better. Out of 100 nuts, only two-thirds, on an average, will be found to vegetate. The plants are then to be set out at intervals of thirty or forty feet—the latter if ground can be spared—and the depth will be regulated by the nature of the soil, and the nut must not be covered with earth. The plants require, in exposed situations, to be shaded for one and even two years, and no lalang grass must be permitted to encroach on their roots. A nursery must be always held in readiness to supply the numerous vacancies which will occur from deaths and accidents. The following may be considered the average cost of a plantation, until it comes into bearing:—

FIRST COST—100 ORLONGS OF LAND.

	Spanish dollars.
Purchase money of land, ready for planting, ...	1,000
7,000 nuts at 1½ dollars, per 100.	105
Houses of coolies, carts, buffaloes, &c., &c., ...	100
Spanish dollars, ...	1,205

YEARLY COST OF SEVEN YEARS.

First year, 10 laborers at 3 dollars per month, including carts, &c., ...	360
Wear and tear of buildings, carts, and implements, ...	50
Overseer, at 7 dollars per month, ...	84
Quit-rent, average, ...	50
Nursery and contingencies,...	50
Total per annum, ...	594
Seven years at the rate will be, ...	4,158
Total, Spanish dollars, ...	4,752

To this sum interest will have to be added, making, perhaps, a sum total of 6,000 Spanish dollars, and this estimate will make each tree, up to its coming into bearing, cost one Spanish dollar at the lowest. The young tree requires manure, such as putrid fish and stimulating compounds, containing a portion of salt. On the Coromandel coast, the natives put a handful of salt below each nut on planting it. The cultivators of Kiddah adopt a very slovenly expedient for collecting the fruit. Instead of climbing the tree in the manner practised by the natives on the Coromandel coast, by help of a hoop passing round the tree and the body of the climber —and a ligature so connecting the feet as will enable him to clasp the tree with them—the Malays cut deep notches or steps in the trunk, in a zig zag manner, sufficient to support the toes or the side of the foot, and thus ascend with the extra aid only of their arms. This mode is also a dangerous one, as a false step, when near the top of a high tree, generally precipitates the climber to the ground. This notching cannot prove otherwise than injurious to the tree. But the besetting sin of the planter of coco nuts, and other productive trees, is that of crowding. Coco-nut trees,

whose roots occupy, when full grown, circles of forty to fifty feet in diameter, may often be found planted within eight or ten feet of each other; and in the native campongs all sorts of indigenous fruit trees are jumbled together, with so little space to spread in, that they mostly assume the aspect of forest trees, and yield but sparing crops. The common kinds of the coco-nut, under very favorable circumstances, begin to bear at six years of age; but little produce can be expected until the middle or end of the seventh year. The yearly produce, one tree with another, may be averaged at 80 nuts the tree; where the plantation is a flourishing one—assuming the number of trees, in one hundred orlong, to be 5,000—the annual produce will be 400,000 nuts, the minimum local market value of which will be 4,000 Spanish dollars, and the maximum 8,000 dollars. From either of these sums 6 per cent, must be deducted for the cost of collecting, and carriage, &c. The quantity of oil which can be manufactured from the above number of nuts will be, as nearly as possible, 834 piculs of 133¾lbs.

The average price of this quantity, at 7 dollars per picul	5,838
Deduct cost of manufacturing, averaged at one-fourth, and collecting, watching, &c.	2,059
Profit, Spanish dollars	3,779

The Chinese, who are the principal manufacturers of the oil, readily give a picul of it in exchange for 710 ripe nuts, being about 563 piculs of oil out of the total produce of the plantation of 100 orlongs. The price of coco-nut oil has been so high in the London market as £35 per ton, or about an average of ten dollars per picul. It is said that English casks have not been found tight enough for the conveyance of this oil to Europe, but if the article is really in great demand, a method will no doubt be discovered to obviate this inconvenience. So long, however, as the cultivator can obtain a dollar and a half, or even one dollar for 100 nuts, he will not find it profitable to make oil, unless its price greatly rises. Soap is manufactured at Pondicherry from this oil, but it is not seemingly in repute; the attempt has not been made in Pinang with a view to a market. There is scarcely any coir rope manufactured at this island, so that the profit which might (were labor cheaper) arise from this application of the coco-nut fibre, is lost. The shell makes good charcoal; the leaves are scarcely put to any purpose, the nipah or attap being a superior material for thatching. The coco-nut tree is extremely apt to be struck by lightning, and in such cases it is generally destroyed. It is a dangerous tree, therefore, to have close to a house. If the trees are widely planted, coffee may be cultivated under their shade. It is generally believed that the extracting of toddy from this tree hastens its decline. The Nicobar and Lancavi Islands used partly to supply the Pinang market with this indispensable article; but their depopulation has

COCOA-NUT PALM.

greatly reduced the quantity. On the whole it may be said that there is no cultivation which insures the return of produce with so much certainty as that of the coco-nut tree; and as Rangoon, the Tenasserim coast, and Singapore will, probably, always remain good markets for the raw nut, there appears to be every chance of the value of the produce affording ample remuneration to the planter. *Coco-nut beetle.*—The chief natural enemy of this tree is a destructive species of elephant-beetle (*Oryctas Rhinoceros*), which begins by nibbling the leaves into the shape of a fan; it then perforates the central pithy fibre, so that the leaf snaps off; and lastly, it descends into the folds of the upper shoot, where it bores itself a nest, and if not speedily extracted or killed, will soon destroy the tree. At Singapore, on account of the depredations of this beetle, the difficulties have been considerable. In Pinang and Province Wellesley it has only been observed within the last two years, and it is believed to have come from Keddah. A similar kind of beetle is, however, found on the Coromandel coast. The natives of Keddah say that this insect appears at intervals of two, three, or more years. Its larvæ, which are also very formidable insects or grubs, about three inches long, with large reddish heads, are found in decaying vegetable matter. It is when the tree has made considerable progress, however, that the parent insect does most mischief. When they are from one to two years old, throwing out their graceful branches in quick succession with the greatest vigor, and promising in three or four years more to yield their ruddy fruit, this destructive enemy begins to exercise his boring propensities; and, making his horn act as an auger, he soon penetrates the soft and yielding fibre of the young tree, and if not discovered in time, destroys the leading shoot or branch. The only remedy which has been adopted in Ceylon, is the following:—Several intelligent boys are provided each with an iron needle or probe, of about a foot long, with a sharp double barbed point, like a fish-hook, and a ring handle; they go through the plantation looking narrowly about the trees, and when they perceive the hole in the trunk, which indicates that the enemy is at work, they thrust in the barbed instrument and pull him out. Sometimes he may only have just commenced, when his capture is more easily effected, but even should he have penetrated to the very heart of the tree, the deadly needle does not fail in its errand, but brings the culprit out, impaled and writhing on its point. This is the only known way of checking the ravages of this beetle, except destroying its larvæ. Some cultivators, however, think pouring salt water or brine on the top of the tree, so as to descend among the folds of the upper shoots, a good plan to get rid of the larvæ. Nearly two million coco-nuts are shipped annually from Bahia. From Ceylon, 114,000 coco-

nuts were shipped in 1851, and 70,185 in 1852. Coco-nut oil; 98,159 gallons were shipped from Ceylon in 1852; 359,233 gallons in 1851. The prices of Ceylon oil have ranged from £31 to £33 10s. per ton; of Cochin oil, £34 to £35, within the last two years. The price per leaguer in Colombo, without casks, has been £8 10s. to £9. *Copperah* is the name given by the natives to the dried kernel of the ripe nut after it has been exposed to the sun on mats. It has recently been shipped to England in this state for the purpose of converting into oil. The exports of copperah from Ceylon were, in 1842, 115 cwts.; in 1843, 2,194; in 1844, 2,397; and in 1852, 39,174 cwts. The returned value of the copperah or kernels exported from Ceylon, as entered in the Custom House books, is—

1840	£2,508	1847	£6,503
1841	1,460	1848	12,639
1842	3,022	1849	7,819
1843	5,795	1850	4,166
1844	6,194	1851	9,678
1845	3 282	1852	13,325
1846	5,517		

632 cwts. of poonac (being the refuse or cake, after expressing the oil) were exported from Ceylon in 1842. It is worth there about £10 the ton. The oil from the nut is obtained for culinary purposes by boiling the fresh pulp, and skimming it as it rises. That for exportation is usually obtained by pressing the copperah in a simple press turned by bullocks. Recently, however, steam power has been applied in Colombo, with great advantage. About 2½ gallons of oil per 100 nuts, are usually obtained. It is requisite that care should be taken not to apply too great and sudden a pressure at once, but by degrees an increasing force, so as not to check the conducting channels of the oil in the press. In many of the colonies the oil is expressed by the slow and laborious hand process of grating the pulp. The quantity shipped from Ceylon was 2,250 tons, in 1842; 3,985 in 1843; 2,331 in 1844; 1,797 in 1845. The quantity in gallons shipped since, was 101,553 in 1846; 197,850 in 1847; 300,146 in 1848; 867,326 in 1849; 407,960 in 1850; 442,700 in 1851; and 749,028 in 1852. The duty on importation is, of and from British possessions, 7d. and 7-8ths. per cwt.; if the produce of foreign possessions, 1s. 3¼d. per cwt. In the close of 1852, the price of coco-nut oil in the London market was, for Ceylon, £32, £33, to £33 10s. per ton; Cochin, middling to fine, £34 to £35. The following return shows the Custom House valuation of the oil shipped from Ceylon for a series of years, and which is of course much below its real value:—

1839	£26,597	1846	£ 7,939
1840	32,483	1847	19,142
1841	24,052	1848	24,839
1842	34,242	1849	34,831
1843	43,874	1850	38,035
1844	24,067	1851	31,444
1845	15,945	1852	58,045

Among the coco-nut oil exported from Ceylon, in 1849, there were 47,427½ gallons, valued at £3,595, the whole of which, I believe, was Cochin oil; the raw material of this kind not being, like the copperah generally in Ceylon, subjected to the action of fire, the product is finer, and fetches a better price in the London market. Amongst the imports from British possessions in Asia, were 2,600 cwts., of copperah (dried coco-nut kernels, from which oil is expressed), valued at £1,100; amongst the imports re-exported to Great Britain, we find 870 cwts. of the same article, valued at £300. Of the oil exported a quantity of 11,000 gallons was shipped for the United States. About 600,000 piculs of cocoa-nut oil are annually exported from Siam. A large quantity of oil is made in Trinidad, chiefly on the east coast, where, in one locality, there is an uninterrupted belt of coco-nut palms fourteen miles in extent. They usually bear when five years old. The cultivation of the coco-nut in a proper soil presents a very profitable speculation for small capitalists. Whether sold at the rate of a dollar per hundred in their natural state, to captains of ships, who freely purchase them, or manufactured into oil, they are a very remunerative product. Each tree in the West Indies is calculated to produce nuts to the value of one dollar yearly. There is one thing to which we should draw the attention of chemists and other scientific men. For twenty-four or even forty-eight hours after its manufacture this oil is as free from any unpleasant taste as olive oil, and can be used in lieu of it for all culinary purposes, but after that time it acquires such a rancid taste as to be wholly unpalateable. If any means could be discovered of preventing this deterioration in quality and preserving it fresh and sweet, it could compete with olive oil, and the price and consumption would be largely raised.

COCOA-NUT OIL IMPORTED INTO THE UNITED KINGDOM.

A London coco-nut oil soap was found, on analysis by Dr. Ure, to consist of:—

Soda,	4·5
Coco-nut lard,	22·0
Water,	73·5
	100·0

This remarkable soap was sufficiently solid; but it dissolved in hot water with extreme facility. It is called marine soap, because it washes linen with sea water. Of the six principal vegetable oils, namely—palm, cocoa-nut, castor, olive, linseed and rape, the first four are imported in the state of oil only; the two last chiefly as seed. The proportion in which they were imported is shown in the following tables; and if to these quantities are added about a million and a half cwt. of tallow, and nearly twenty thousand tons of whale oil and spermaceti, they will nearly represent the total quantity of oil imported into Great Britain.

Cocoa-nut Oil-cake.—It has been observed by Evelyn that one bushel of walnuts will yield fifteen pounds of peeled kernels, and these will produce half that weight of oil, which the sooner it is drawn is the more in quantity, though the drier the nut the better its quality. The cake or marc of the pressing is excellent for fattening hogs and for manure. Among the various seeds used in the manufacture of oil-cake, flour of linseed is the most important. Rape seed is also employed, but is considered heating. In Lubeck, a marc, called dodder cake, is made from the *Camelina sativa*. Inferior oil-cake is made from the poppy in India. Cotton-seed cake has lately been recommended on account of its cheapness, being usually thrown away as refuse by the cotton manufacturers. It is extensively used as a cattle food, in an unprepared state, in various parts of the tropical world, and to a limited extent in Great Britain. The cost of seed, freight included, was 2d. per lb. from Charlestown to Port Glasgow. Cotton oil-cake is now ordered at the same price as linseed cake. The produce of oil-cake and oil from cotton seed is two gallons of oil to one cwt. of seed, leaving about 96 lbs of cake; 8 lbs. is the daily allowance for cattle in England. Cotton seed oil, very pure, is manufactured to a considerable extent at Marseilles, by De Gimezney, from Egyptian seed; and he received a prize medal at the Great Exhibition.—Account of the export of linseed and rapeseed cakes from Stettin, principally to England, in—

The quantity of oil-seed cakes imported into the United Kingdom was in—

	tons.		tons.
1849	59,462	1851	55,076
1850	65,055	1852	53,617

Cargoes of oil-cake, to the value of £22,207, were exported from the port of Shanghae, in China, in 1849. Seven samples of American oil-cake gave the following results:—

Oil,	11·41
Water,	7·60
Nitrogen,	4·74
Ash,	6·35

From the above figures, the scientific farmer will see that the manure formed by 100 lbs. of oil-cake is more than that derived from 300 lbs. of Indian corn. 300 lbs. of corn contain about 1¼ lbs. phosphoric acid; 100 lbs. oil-cake contain about 2½ lbs.—*Simmonds' Com. Product.*

(2756) COCOA-NUT SHELL. In India the thick fibrous husk is made into the Coir rope, and in Europe into rope, matting brushes, &c.; the substance of the shell is very brittle, and its structure is somewhat fibrous, but it admits of being turned in an agreeable manner. Those shells which are tolerably circular are used for the bodies of cups and vases, the feet and covers being made of wood or ivory. Common buttons are also made of the cocoa-nut shell, and are considered better than those of horn, as they do not, like that material, absorb moisture which causes them to swell and twist.—*Tredgold.*

(2757) COCOA-NUT MILK is made from the kernel. For this purpose the kernel is grated, a

little warm water is poured over it, and the liquid is then poured through an open cloth. This milk is excellent with coffee, and is indispensable for curry.

(2758) COCOA-NUT OIL. Cocos NUCIFERA.

Taynga yennai, TAM.	Narel ka tel, HIND.
Tencaya noona, TEL.	

The native method of making this oil is very simple. The kernel having been removed from the shell and dried is subjected to pressure in a mill, and the oil is expressed, but when prepared in small quantities, the kernel is boiled in water, for a short period; it is then pounded in a mortar, taken out and pressed. The *milk*, as it is called, which exudes, is then boiled over a slow fire, when the oil floats on the top, and being skimmed off is afterwards boiled by itself. Two quarts of oil may be procured from fourteen or fifteen cocoanuts. When fresh, the oil has an excellent flavour. It is used as an unguent on the bodies of the natives, after bathing, and as an oil for the hair. It is employed as a lamp oil, and is manufactured into soap. It is said to have all the virtues of cod Liver oil. The purest oil is obtained by grating the kernel and depositing it in some hollow vessel, to expose it to the heat of the sun, during the day, and the oil drains away through hollow spaces left for the purpose. The Malabar method of making the oil, is by dividing the kernels into two equal parts, which are ranged on shelves made of laths of the Betel-nut palm, or split Bamboo, spaces of half an inch wide being left between each lath. Under these a charcoal fire is lit and kept up for two or three days, in order to dry them. After which they are exposed to the sun on mats, and when thoroughly dried are subjected to pressure in an oil press. The remains of the cocoanut, from which the oil has been extracted, Posknakkull, *Hind.* Tenga Poonak, *Tam.* Tenga Pindee *Tel.* Poonak, *Cing.*, affords an excellent material for feeding pigs, poultry &c., and the best is obtained when the oil is extracted by pressure. The average annual quantity of this oil exported from Madras from 1847-48 to 1852-53 is about Galls. 9,00,000 per annum. Of this by far the largest portion is sent to the United Kingdom and France, the remainder finds its way to Arabia, Mauritius, Bombay and the French (Indian) Ports. The prices of this oil vary considerably in different parts of Southern India. For the quarter ending 31st October 1854 the max: and min: were Rs. 8. 5. 4 at Jubbulpore and Rs. 1. 12. 9 at Mhow per maund. The average of twenty-one large Stations in the Madras Presidency giving Rs. 4. 9. 5 per maund, or about £41-2 per ton. The market-value of "Cochin oil" in London (January 1855) was £46. 10— the average being £46 to 48. The best oil is that exported from Cochin, and the neighbouring ports on the Malabar Coast. It usually fetches 20*s.* per ton more than the Ceylon or Coromandel coast article. In Europe, for Candle and soap manufacture, for lubricating machinery, &c. &c. In India, for making soap, anointing the person, for cookery, lamps and in medicine.—*M. E. Jur. Reports.* A very excellent sample of this oil was shown by Monsieur Godéfroy of Pondicherry—The Canara Local Committee, the Madras Tariff, Soobroya Pillay, Mr. Kholhoff and Lieut. Hawkes also contributed excellent specimens.—*M. E. J. R.*

(2759) COCOA-NUT, DOUBLE. The Double Cocoa-nut of the Seychelles or Mahé islands, is the fruit of the Lodoicea. When preserved whole, and perforated in one or two places, the nut serves to carry water, and some of them hold six or eight pints; and by slicing them in different directions, they are formed into plates, dishes, drinking cups &c. known in the Islands as Vaisselle de l' isle Prasten. The crown of the trunk is eaten like the American cabbage palm. The down attached to the young leaves serves for filling mattresses and pillows; the ribs of the canes and fibres of the petiole are fabricated into baskets and brooms and the young canes are plaited to form hats. The Lodoicea attains a height of eighty or ninety feet. It might be introduced into India with advantage. Germinating nuts were sold in London in 1854 at £10 a piece.—*Seeman.*

(2760) COCOON. A term applied to the ball formed by the silk-worm, by winding around itself the silk which it spins.—*Faulkner.*

(2761) COCOS, a genus of plants belonging to the natural order of palms. It is thus defined by von Martius:—Both male and female flowers on the same spadix. Spathe simple; flowers sessile. Males calyx 3-leaved; corolla of 3 petals; stamens 6; a rudiment of a pistil. Females 3 sepals and 3 petals rolled together; ovary 3-celled; stigmas 3, sessile; drupe fibrous; putamen with three pores at the base; albumen homogeneous, hollow; embryo next one of the pores at the base; stems either lofty or middle-sized, slender ringed, or crowned by the bases of the petioles, with a pale fibrous wood; leaves pinnated; the pinnæ lanceolate or linear; flowers pale yellow; drupes brown, green, or orange-colour, rather dry. The genus contains several species.—*Eng. Cyc. Vol.* II. *page* 53.

(2762) COCUM OIL, or butter, is obtained from the seeds of a kind of mangosteen (Garcinia purpurea) and used in various parts of India to adulterate ghee or butter. It is said to be exported to England for the purpose of mixing with bears' grease in the manufacture of pomatum. It is a white, or pale greenish yellow, solid oil, brittle, or rather friable, having a faint but not unpleasant smell melting at about 95 degrees, and when cooled after fusion remaining liquid to 75 degrees—*Simmonds.*

(2763) COD.

Kabliau, DAN.	Gadus, LAT.
Kabeljaauw, Baukaelja, DUT.	Bacalhao, PORT.
Marue, FR.	Bacalao, SP.
Kabljau, Bakalau, GER.	Kabeljo, SW.
Baccala, Baccalare, IT.	

A well-known species of white prolific fish. Two kinds of prepared cod are distinguished—*pickled cod*, and *dried cod*. The former is gutted, salted, and then barelled; and the latter is simply dried and cured.—*Faulkner*.

(2764) CODILLA OR TOW. The part separated or picked out in cleaning hemp or flax. —*Faulkner*. Is composed of the short fibres of the flax. The quantity of Flax and Tow, or Codilla of Hemp and flax imported into Great Britain increased from 13,686 tons in 1801 to 95,123 tons in 1853.—*Royle*.

(2765) CODIPASSAELI KEERAY, *Tam.* BASELLA ALBA. *Syn.*

Bayl ke butchla ke baujee, DUK.	Kalumbi, SANS.
Tinghe Batsalikoora, TEL.	*Ainslie, p.* 253.

(2766) CODLÆUM CHRYSOSTICTON. *Syn* CROTON VARIEGATUM. Variegated croton. This shrub with handsome variegated leaves is sometimes seen in Tenasserim gardens.—*Mason*.

(2767) COD LIVER OIL. *Lat.* Morrhuæ oleum. Is obtained from the liver of the common cod (*Asellus*), and has long been in use as a remedy in the northern parts of Europe for pulmonary consumption, especially in the incipient stage. It is now in general use among all European practitioners. This oil has a disagreeable nauseous taste, to overcome which, it may be floated on milk, some aromatic water, a bitter infusion, cold tea or coffee, or wine.—*Faulkner*.

(2768) COFFEA, a Cinchonaceous genus, consisting of many species of tropical berry bearing shrubs, one of which, *Coffea Arabica*, is celebrated for the agreeable stimulating effect of an infusion of its roasted albumen. This substance, the coffee of commerce, is to that plant what the flour is to corn, the white meat to cocoa-nut, and the aromatic ruminated substance to a nutmeg. It is a secretion formed in the interior of the seed, and enveloping the embryo plant, for whose support it is destined when it first begins to germinate: it constitutes the principal part of the seed, the embryo itself being a minute body lying in a cavity at one end of the albumen. Unskilful observers are often unable to find the embryo; but it may readily be seen by the following simple means:—Take a new sample of small fine unroasted Mocha coffee, and throw it into boiling water; the embryo will, after a little while, be expelled with force from the albumen in a majority of cases.—*Engl. Cyc. page* 58. Wight describes Coffea alpestris, Arabica, Grumelioides, and Wightiana.

(2769) COFFEE. The berry of Coffea Arabica.

Caffe, IT.	Chaube, TURK.

The Coffee plant is a native of Yemen, in Arabia, whence it has been introduced into other parts of the world. The Coffee plant thrives well all over India in the open air, and bears annually a few berries even one thousand miles further to the north west, that is, in the Botanic Garden at Saharunpore, in 28° of north latitude. But the cold in winter is too great for this cultivation so far north, though it might probably be carried as far as the Rajmahl Hills, and into Assam and the Silhet Hills, or south into the Malayan Peninsula.—*Royle's Productive Resources of India. Coffea Arabica* is an ever-green shrub, with oval shining wavy sharp-pointed leaves white fragrant five-cleft clustered corollas with projecting anthers, and oblong pulpy berries, which are at first of a bright red, but afterwards become purple. It is stated by Niebuhr to have been brought from Abyssinia to Yemen by the Arabs from a country similar to their own plains and mountains. By that people it has for ages been cultivated in the hilly range of Jabal, in a healthy temperate climate, watered by frequent rains and abounding in wells and water-tanks. Here the plants are grown in grounds that are continually irrigated, and in soil from one to one and a half foot deep. Among the plantations are interspersed various kinds of trees, whose shade has a beneficial effect upon the coffee-bushes. When in flower they diffuse a most delicious fragrance, in the midst of which the natives fix their habitations. The fruit begins to ripen in February; and when the seeds are prepared, they are conveyed to the city of Beitel Fakih, whence part goes to Mocha, and another portion to Hodeida and Loheia, whence it finds its way to Djedda and Suez for the Turkish and European markets.—*Engl. Cyc. page* 59. The coffee-plant begins to produce fruit when two or two and a half years old; but the quality of the seeds from young stems is not so good as that from stems four or five years old. The size and colour of the bean (as the inner part of the seed is called) vary considerably, those from the West Indies being larger than those from the East. Much more depends upon the manner of roasting and making the Coffee, than upon the quality of the bean. The superiority of French Coffee, in the preparation of which little or no Mocha Coffee is used, proves this position. Beans of a good quality are hard and heavy, sink quickly in water, are of a light yellowish-green colour, not discoloured or black,

and possess the odour of coffee, which, though faint, is peculiar, and are free from any damp smell. Beans recently collected, or only two or three months from the tree, are not so good as those about a year old; when older than this they become deteriorated. From the analysis of Seguin and Schrader, coffee consists of coffee-bitter (impure cafeine), solid fat, resin, a little aromatic principle, gum, albumen (this albumen, according to Seguin, unites with the yellow coffee-bitter, and forms a green), and lignin.—*Engl. Cyc. Vol.* II. *page* 63. The taste of raw coffee is somewhat sweetish; but the application of heat in the process of roasting produces important changes. The bean increases to nearly twice the original size, while it loses about one third of its weight: a powerful and agreeable odour is evolved, and a large quantity of empyreumatic oil, which appears in small drops on the surface, is formed along with a bitter principle, probably by an alteration in the cafeine, and of the saccharine matter. The roasting should take place in a close revolving iron cylinder, over a clear but moderate fire, and should not be carried too far: when the beans have acquired a light chesnut colour, the roasting should be discontinued. The beans are then to be cooled quickly by being tossed up into the air, and the grinding, or rather rough pounding, should be performed in a covered mortar or mill. The drink should be prepared from it as soon as possible, by infusion, which is preferable, unless some apparatus be employed by which a kind of decoction is made in a close vessel. About half an ounce of coffee powder should be used for every eight ounces (half a pint) of water. In Britain the roasting is generally carried too far; and the subsequent parts of the process, instead of being performed immediately, are often postponed for days or even weeks, by which the aroma is dissipated: when made, the liquid is generally deficient in strength and clearness. The employment of white of egg or fish-skin for clarification is decidedly objectionable: clearness is thus purchased, but at the expense of the strength. The addition of milk (which should always be hot) and of sugar heightens the nourishing qualities of this beverage, and in the morning renders it a more substantial article for breakfast. When taken after dinner to promote digestion it should be without milk, and, where the palate can be reconciled to it, without sugar. The adulterations of ground coffee are very considerable; the most important of these is chicory, a dark brown powder made from the roasted roots of the *Cicorium Intybus*. It is by some thought to be perfectly harmless, and an agreeble addition to the coffee: it is not however of so much value, and should not therefore be added to the coffee by the dealer, but sold separately, so that those who desire to add it may purchase it themselves. Various other seeds are used either as imitations or adulterations of coffee, such as Rye-Chick Peas (*Cicer arietinum*), Broom Seeds (*Spartium scoparium*), the yellow Water-Iris (*Iris pseudacorus*), and the Dandelion root (*Leontodon taraxacum*). It has been suggested to use the leaves of the coffee-plant in infusion the same as those of the tea-plant, and it is said they form a very agreeable beverage; but the berries are too valuable in themselves to permit the trees being injured by the loss of their leaves, as they would be were there any demand for them as an article of diet. —*Engl. Cyc. page* 60. Home consumption and Revenue of Coffee for the years:—

In a little treatise on coffee and its adulterations, published in 1850 it was estimated that not less than 18,000,000, lbs. of vegetable matter of various kinds were sold annually, under the deceptive name of coffee. Three-fourths of these 18,000,000 lbs. of pretended coffee were composed of chicory, and the remaining fourth of other ingredients prejudicial to health, as well as a fraud upon the revenue. The various substances used in adulterating both chicory and coffee, when sold in the powdered state, have been specifically pointed out and set forth from time to time in memorials from the trade and the coffee-growers. Mr. M'Culloch and other competent judges set down the actual consumption of chicory in the United Kingdom at 12,500 tons per annum. When we consider the vast difference of price between chicory and coffee, as purchased by the wholesale dealer, the temptation to its fraudulent use was obviously great, and there was no penal restriction against it. In the year 1832 chicory was first imported into England, subject to a duty equivalent to that levied upon colonial coffee, and permitted to be sold by grocers *separately* as chicory; but notices were at the same time issued, that the legal penalties would be rigidly enforced, if discovered mixed with coffee. In 1840, in consequence of memorials from the grocers and dealers in chicory, and also from the circumstance of exceedingly high rates then ruling for coffee, together with the disruption of our commercial relations with China, simultaneously advancing the price of tea (thus rendering both these popular beverages excessively dear to the consumer), an order was

issued from the Treasury to the Excise Board, authorizing the admixture of chicory with coffee; a duty, however, being still maintained on the former of £20 per ton on the kiln-dried, and 6d. per lb. on the powdered root, when imported from abroad. The changes in the sources of supply, within the last fifteen or sixteen years, have been very remarkable. The British possessions in the East have taken the place which our islands of the West formerly occupied. The British West Indies have fallen off in their produce of Coffee from 30,000,000 to 4,000,000 lbs. Ceylon which, fifteen years ago, had scarcely turned attention to coffee, now exports nearly 35,000,000 lbs. San Domingo, Cuba, and the French West India colonies are gradually giving up coffee-cultivation in favor of other staples; and it is only Brazil, Java, and some of the Central American Republics that are able to render coffee a profitable crop. The export crop of Brazil (the greatest coffee-producing country), grown in 1850, for the supply of the year ending July, 1851, amounted to no less than 302,000,000 lbs., of this a large quantity remained in the interior to supply the deficiency of the current year. It is scarcely thirty years ago that the coffee-plant was first introduced into Bengal by two refugees from Manilla; and the British possessions in the East Indies now yield 42,000,000 lbs. Sufficient extent has not yet been given to enable it to be decided in what district of *Continental* India it may be most advantageously cultivated. It is in the fine island of Ceylon, however, that coffee-culture has made the most rapid progress. It is an imporant fact that the supply of coffee from Ceylon, even at the present moment, and irrespective of land already planted but not yet come into full bearing, is in excess of the whole consumption of Great Britain, and the planter is thus compelled to carry the surplus to continental markets. The exports of coffee from Ceylon have been rather stationary the past three years, averaging about 300,000 cwt. In the sixteen years ending with 1851, Ceylon had exported 130,083 tons of coffee! The present *produce* of the various coffee-growing countries in the world, may be set down at the following figures:

SOUTH AND CENTRAL AMERICA.	Millions of lbs.
Costa Rica, ...	9

Malabar and Mysore, ...	5
Arabia (Mocha), ...	3
	616 = 275,000 tons.

I shall now proceed to describe the cultivation of the tree and preparation of the berry, as carried on in different countries.

Cultivation of Mocha.—In Arabia Felix, the culture is principally carried on in the kingdom of Yemen, towards the cantons of Aden and Mocha. Although these countries are very hot in the plains, they possess mountains where the air is mild. The coffee is generally grown half way up on their slopes. When cultivated on the lower grounds it is always surrounded by large trees, which shelter it from the torrid sun, and prevent its fruit from withering before their maturity. The harvest is gathered at three periods; the most considerable occurs in May, when the reapers begin by spreading cloths under the trees, then shaking the branches strongly, so as to make the fruit drop, which they collect and expose upon mats to dry. They then pass over the dried berries a heavy roller, to break the envelopes, which are afterwards winnowed away with a fan. The interior bean is again dried before being laid up in store. The principal coffee districts are Henjersia, Tarzia, Oudein, Aneizah, Bazil, and Weesaf. The nearest coffee plantations are three-and-a-half days journey (about 80 miles) from Aden. The following information is derived from Capt. S. B. Haines of the Indian Navy, formerly political agent at Aden.

A camel load is about 400 lbs = 25 frazlas or bales.

	G.C.	Commassees.
The price of ditto inland,...	31	41
At Mocha, duty to Dewla uncertain...

Camel hire to the coast, ...	12	50
Cost from Sana to Mocha, ...	44	15

Coffee is brought into the Sana market in December and January from the surrounding districts. The varieties are—

1. Sherzee, best—price 1 G.C. frazla 25 butsha.
2. Onceaime.
3. Muttanee,
4. Sharrazee.
5. Hubbal from Aniss.
6. Sherissee from ditto—price per frazla 1 G.C. 15 B.

The nearest place to Sana where the coffee tree grows, is at Arfish, half a day distant. Attempts have been made to introduce the shrub in the garden of the Imaum at Sana, but without success, ascribed to cold. Kesher is more prized at Sana; best is Anissea, and is sold at a higher price than other coffee, namely, g. c. 12 per 100 lbs.; inferior, at from 4, 5, and 6. Rain falls in Sana three times in the year. 1st. In January, in small quantities. 2nd. Beginning of June, when it falls for eight or ten days. By this time the seed is sown, and the cultivators look forward to the season with anxiety. 3rd. In July, when it falls in abundance. A few farmers defer sowing till this period, but it

is unusual, when they expect rain in June. The coffee plant is mostly found growing near the sides of mountains, valleys, and other sheltered situations, the soil of which has been gradually washed down from the surrounding heights, being that which forms its source of support. This is afforded by the decomposition of a species of claystone (slightly phosphoritic), which is found irregularly disposed in company with a few pieces of trap-rocks, amongst which, on approaching Sana from the southward, basalt is found to preponderate. The clay-stone is only found in the more elevated districts, but the debris finds a ready way into the lower country by the numerous and steep gorges which are conspicuous in every direction. As it is thrown upon one side of the valley, it is carefully protected by means of stone walls, so as to present to the traveller the appearance of terraces. The plant requires a moist soil, though much rain does not appear necessary. It is always found in greater luxuriance at places where there is no spring. The tree at times looks languid, and half withered; an abundant supply of water to the root of the plant seems necessary for the full growth and perfection of its bean.

Progress of Cultivation in India.—There are said to be ten varieties of the coffee, but only one is found indigenous to India, and it is questionable if this is not the Mocha species introduced from Arabia. The cultivation of this important crop is spreading fast throughout the east, and has been adopted in many parts of Hindostan. In the Tenasserim provinces, on the table land of Mysore, in Penang, and especially in the islands of Bourbon and Ceylon, it is becoming more and more an object of attention. It is known to have given good produce in Saugur and the Nerbudda; also in Mirzapore. as well as Dacca, and other parts of Bengal; Chota Nagpore, Malabar, and Travancore. From three to four million pounds of coffee are now exported from the Indian presidencies annually. The highest quantity was four and quarter million pounds in 1845, but the progress of culture, judging from the export, has been small. On the hilly districts on the east coast of the Gulf of Siam, the cultivation is carried on on a limited scale. The annual produce is not much more than about 400 cwt., although it is understood to be increasing. The quality of the berry is reckoned to be nearly equal to Mocha, and it commands a high price in the English market. The soil recommended in India is a good rich garden land, the situation high and not liable to inundation, and well sheltered to the north-west, or in such other direction as the prevailing storms are found to come from. A plantation, or hill affording the shrubs shade, has been found beneficial in all tropical climates, because, if grown fully exposed to the sun, the berries have been found to be ripened prematurely. The spot should be well dug to a depth of two feet before the trees are planted out, and the earth pulverised and cleared from the roots of rank weeds, but particularly from the coarse woody grasses with which all parts of India abound. The best manure is found in the decayed leaves that fall from the trees themselves, to which may be added the weeds produced in the plantation, dried and burnt. These, then, dug in, are the only manure that will be required. Cow-dung is the best manure for the seed-beds. The seed reserved for sowing must be put into the ground quite fresh, as it soon loses its power of germination. Clean, well-formed berries, free from injury by insects, or the decay of the pulp, should be selected. These berries must be sown in a nursery, either in small, well manured beds, or in pots in a sheltered spot, not too close, as it is well to leave them where sown until they acquire a good growth; indeed, it is better if they are removed at once from the bed where they are sown, to the plantation. Here they should be planted as soon as they have attained two years of age, for be it remembered, that if they are left too long in the nursery, they become unproductive and never recover. The distance at which they should be put out in the plantation need not exceed eight feet apart in the rows, between which, also, there should be eight feet distance. The seedlings appear in about a month after the seed is sown. The culture requisite is, in the first instance, to afford shade to the young plants; many consider that this shelter should be continued during the whole period of their culture; but this is somewhat doubtful, as it has been found that plants so protected are not such good bearers as those which are exposed. The best plants for this purpose are tall, wide-branching trees or shrubs without much underwood. The other culture, requisite is only to keep the ground tolerably clean from weeds, for which one cooly on from five to ten biggahs is sufficient. He should also prune off decayed or dead branches. This treatment must be continued until the fourth year, when the trees will first begin bearing, and, after the gathering of each crop, the trees will require to be thinned out from the superabundant branches, their extremities stopped, and the tops reduced to prevent their growing above seven or eight feet in height; the stems, also, should be kept free from shoots or suckers for the height of at least one foot, as well as clear from weeds. Irrigation must be frequent during the first year that the plants are removed to the plantation, and may be afterwards advantageously continued at intervals during the dry and hot weather, as a very hot season is found unfavorable to the plant, drying up and destroying the top branches and the extremities of the side shoots; whilst, on the other hand, a very long rain destroys the fruit by swelling it out and rotting it before it can be ripened: hence it is necessary to attend to

a good drainage of the plantation, that no water be anywhere allowed to lodge, as certain loss will ensue, not only of the crop of the current year, but most frequently of the trees also, as their roots require to be rather dry than otherwise. The crop will be ready to gather from October to January, when the ripe berries should be carefully picked from the trees by hand every morning, and dried in the shade, the sun being apt to make them too brittle; they must be carefully turned to prevent fermentation, and when sufficiently dry the husks must be removed, and the clean coffee separated from the broken berries. After being picked out and put aside, and then again dried, it is fit to pack. The first year's crop will be less than the succeeding ones, in which the produce will range from ½ a lb. to 1 lb. in each year.—(Simmond's "Colonial Magazine," vol. xv.)

Ceylon.—Coffee is stated to have been introduced into this island from Java, somewhere about the year 1730. It was extensively diffused over the country by the agency of birds and jackalls. In 1821 its cultivation may be said to have partially commenced, and in 1836, it had become widely extended through the Kandyan provinces. In 1839 not a tree had been felled on the wide range of the Himasgaria mountains. In 1840 a small plantation was, for the first time, formed. In 1846 there were fifty estates, then averaging, each, 200 acres of planted land, and yielding an average crop of 80,000 cwt. of coffee. Every acre is now purchased in that locality, and in large tracts, or there would have been twice the number of estates in cultivation. In 1848, the Galgawatte estate, situate in this range, at an elevation of 4,000 feet, containing 246 acres, of which 72 were planted, was purchased by Mr. R. D. Gerard, for £1,600. The quantity of land which had been brought under cultivation with coffee in this island in the ten years previous to the last reduction of duty in 1844, was, in round numbers, 25,000 acres; but so rapid was the subsequent increase, that in the succeeding three years, that extent of land was doubled; so that, in 1847, there were upwards of 50,000 acres of land under cultivation with coffee, giving employment to 40,000 immigrant coolies from the continent of India, and upwards of two millions of capital were invested in the cultivation of this staple. The quantity of land under culture with coffee by Europeans, was about 55,000 acres in 1851. Allowing 20,000 acres to produce the quantity of native coffee exported, and 5,000 for that consumed in the island, the total extent of coffee cultivation in Ceylon, European and native, will be 80,000 acres. The produce exported in 1849 was 373,593 cwt., while in the year 1836, when attention was first directed to this island as a coffee-producing country, the crop was not more than 60,330 cwt. Large profits were made by the first planters, more capital was introduced, until, between the year 1840 and 1842, the influx of capitalists, to undertake this species of cultivation, completely changed the face of the colony, and enlarged its trade, and the produce of coffee in sixteen years has increased six-fold. The general culture resembles the practice in Java. Of the Ceylon coffee, that grown about Ramboddi fetches the highest price, from the superiority of the make, shape, and boldness of the berry. The weight per bushel, clean, averages 56lbs; 57½lbs. is about the greatest weight of Ceylon coffee. The lowest in the scale of Ceylon plantation coffee is the Eoombera, which averages 54½lbs., clear, per bushel. The following have been the prices of good ordinary Ceylon coffee in the port of London for the last eight years in the month of January: 1853, 46s. to 48s; 1852, 40s. to 42s; 1851, 38s. 6d. to 40s. 6d.; 1850, 56s. 6d. to 57s. 6d; 1849, 31s. to 32s. 6d.; 1848, 31s. 6d. to 33s,; 1847, 39s. 6d. to 41s. 6d.; 1846, 49s. to 50s. Forest lands are those usually planted in Ceylon, and the expense attendant on clearing and reclaiming them from a state of nature, and converting them into plantations, is estimated to average £8 per acre. The lowest upset price of crown lands in the colony is £1 per acre. Coffee planting has failed over a considerable portion of the southern province of the island, where the experiment was tried. The temperature was found to be too equable, not descending sufficiently low at any time to invigorate the plant; which, though growing luxuriantly at first, soon became weak and delicate. Nurseries are established for young plants. The districts in which the coffee is principally cultivated, extend over nearly the whole of the hilly region, which is the medium and connecting link between the mountainous zone and the level districts of the coast. The mania for coffee planting has recently subsided, in consequence of the barely remunerative returns at which that article has been sold, ascribable partly to over-production, and in some measure, perhaps, to the temporary glut of foreign coffee thrown on the British market by the reduction of the duty. As regards the yield, some estates in Ceylon have produced upwards of 15 cwt. per acre, but it is a good estate that will average seven, and many do not give more than 4 cwt. the acre. The shipments from Colombo for five years, are stated below, with the class of coffee:—

	Plantation. cwt.	Native. cwt.	Total. cwt.
1845 ...	75,002 ...	112,889 ...	187,891
1846 ...	91,240 ...	70,991 ...	162,231
1847 ...	106,198 ...	143,457 ...	249,655
1848 ...	191,464 ...	88,422 ...	279,886
1849 ...	243,926 ...	118,756 ...	362,682
1850 ...	198,997 ...	56,692 ...	255,689
1851 ...	220,471 ...	97,091 ...	317,562

While, in 1839, the total value of the exports from Ceylon was only £330,000, in 1850 the

value of the single staple of coffee was no less than £609,262, and in 1851 had still further increased. I append a memorandum of the quantities of coffee exported from Ceylon since 1836 :—

	Quantity. Cwt.	Value. £
1836	60,329	
1837	34 164	
1838	49.541	
1839	41,863	
1840	68,206	
1841	80,584	196 048
1842	119.805	269,763
1843	94,847	192,891
1844	133,957	267,663
1845	178.603	363,259
1846	173,892	328.781
1847	293 221	456,624
1848	280 010	387,150
1849	373,593	545 322
1850	278,473	609 262
1851	339,744	
Total in 16 years	2.600,832	
Average	162,552	(Ceylon Almanac for 1853.)

The local export duty of two-and-a-half per cent., was abolished from 1st September, 1848.

Peeling, pulping, and winnowing.—The coffee-peeler, used for separating the bean from the pellicle, was formerly a large wheel revolving in a trough, the disadvantage of which was the flattening more or less of the bean when not thoroughly dry. A new machine has been recently introduced, the invention of Mr. Nelson, C.E., of the Ceylon iron works, by which this evil is obviated : its principal being not weight, but simple friction, of sufficient force to break the parchment at first, and, when continued, to polish the bean free from the husk. A very simple winnowing machine for cleaning the coffee as it comes out of the peeler, is attached. From the winnowing machine it runs into the separating machine, which sorts it into sizes, and equalizes the samples, by which a vast amount of time and manual labour are saved. The same principle is intended to be applied by Mr. Nelson to pulping, which will obviate the injury now inflicted by the grater upon the fresh berry. In spite of the greatest care, numbers of the beans in a sample, on close examination, will be found scratched or pecked ; and when the closest attention is not paid, or the person superintending the process is devoid of mechanical skill, the injury is proportionate. The ordinary pulping-mill in use, consists of a cylinder of wood or iron, covered with sheet brass or copper, and punctured similarly to a nutmeg grater. This cylinder, technically called the barrel, runs upon a spindle, which turns a brass pick on each side of a frame. Immediately in a line with the centre upon which it turns, and placed vertical to each other, are two pieces of wood, frequently shod with iron or copper, called "the chops," placed about half an inch apart, or sufficient to allow the passage of "parchment" coffee between them. The lower chop is placed so close to the barrel, yet without contact, that all coffee must be stopped by it and thrown outwards. The upper chop is adjusted to that distance only which will permit the cherry coffee to come into contact with the barrel ; but will not allow the berries to pass on till they have been denuded of their red epidermis by a gentle squeeze against its rough surface. The far greater portion of the pulps are separated by being carried past the lower chops upon the sharp points of the copper, and thrown out behind, and a few are left with the parchment coffee. As from the different sizes of the berries, and their crowding for precedence as they descend from the hopper above to the gentle embrace of the barrel and upper chop, some pass unpulped, the coffee as it comes from the lower chop is made to fall upon a riddle, which separates the unpulped cherries. These are put back again, and passed through a pulper with the upper chop set closer. The secret of working appears to be the proper setting of the chops, and many have been the schemes proposed for reducing this to a certainty. Perhaps, after all, few plans are better than the old wedges, by tightening or loosening of which the chop is kept in the required position. Within the last few years, the machine, has been considerably improved by being formed entirely of iron, cog-wheels being substituted in the place of straps and drums to move the riddle, and the riddle itself is now formed of two sieves, by which the chance of unpulped berries reaching the parchment is lessened. On some estates water-wheels have been put up to drive several pulpers at one time, which otherwise would require from two to four men each to work them, but from the costly buildings and appurtenances which such machinery renders necessary, they are rare. Although the operation of pulping is so simple, it is one which requires the machine to be set in such a way that the greatest quantity of work may be done, or, in other words, the smallest quantity of unpulped berries be allowed to pass through. On the other hand, the berries must not be subjected to injury from the barrel ; for if the parchment skin is pricked through, the berry will appear, when cured, with an unsightly brown mark upon it. Several new coverings for barrels, instead of punctured copper, have been tried ; among others, coir-cloth and wire-net, but the old material is not as yet superseded. After pulping, the coffee in parchment is received into cisterns, in which it is, by washing, deprived of the mucilaginous matter that still adheres to it. Without this most necessary operation, the mucilage would ferment and expose the berry to injury from its highly corrosive qualities. As some

portion of pulp finds its way with the coffee to the cistern, which, if suffered to remain would, by its long retention of moisture, lengthen the subsequent drying process, various methods have been adopted to remove it. One mode is to pass the coffee a second time through a sieve worked by two men; another to pick it off the surfaces of the cistern, to which it naturally rises. In August, 1846, premiums were awarded by the Ceylon Agricultural Society to Messrs. Clerihew and Josias Lambert for the improvements they had introduced into coffee-pulpers, which, by their exertions, had been brought to great perfection. The first improved complete cast-iron pulper received in the island, was made for Mr. Jolly, from drawings sent home by Mr. Lambert to Messrs. B. Hick and Son, engineers. This pulper is one of the most perfect in every respect that has yet been brought into use, the disadvantages belonging to the old machine having been entirely remedied. The sieve crank has a double eccentric action. The chops are regulated by set screws, and the sieve suspended in a novel and secure manner, the whole combining strength and efficacy, together with an elegance of form, which will likewise be appreciated. Mr. W. Clerihew, of Ceylon, submitted to the Great Exhibition a model of his approved apparatus for drying coffee (which has been patented in the name of Robert R. Banks, Great George Street, Westminster), and received the Isis gold medal for the same. The intention is to dry the vegetable and aqueous moisture of the berry. Before this is required, the coffee has previously undergone the process of pulping, or removal from the soft fleshy husk. Here let Mr. Clerihew describe the advantages for himself. "When the coffee berry is picked from the tree it bears a close resemblance to a ripe cherry, both in size and appearance: and several processes have to be gone through before the article known in commerce as coffee is produced. In the first place, the pulpy exterior of the cherry has to be removed by the process of pulping, which separates the seed and its thin covering called the parchment, from the husk. When the pulping process is completed, we have the parchment coffee by itself in a cistern, and the next process consists in getting rid of the mucilage with which it is covered." Having become assured, both by experiment and by Liebig's reasoning, that the successive stages of decomposition were wholly ascribable to the action of the stagnant air which occupies the interstices between the beans, and taking into account that a mass of coffee presented a medium pervious to air, it occurred to Mr. Clerihew that it was possible, by means of fanners, working on the exhausting principle, so to withdraw air from an enclosed space as to establish a current of air through masses of coffee spread on perforated floors, forming the top and bottom of that space. The plan he carried into execution at Rathgoongodde plantation in 1849. No sooner was the plan put in operation than, instead of stagnant air occupying the interstices of the beans and gradually acting on them, a stream of air was established and flowing through the mass of coffee, each bean of it became surrounded by a constantly renewed atmosphere of fresh air.

Java.—When Arabia enjoyed the exclusive monopoly of coffee, it could not be foreseen that one day the island of Java would furnish for the consumption of the world from 125 to 130 millions of pounds per annum. The cultivation was introduced by M. Zwendenkroom, the Governor-General of Batavia, who obtained seeds from Mocha, in 1723. According to official statements the following are the exports. In 1839 there were exported 46,781,729 kilogrammes, valued at 48 million florins. Eight years labor, 1833 to 1841, brought its produce of coffee from 12 million kilogrammes annually, up to 55 millions. In 1846, the exports were 916,876 piculs, but in 1850, they were only 14,801 piculs. The total coffee crop of Java was in 1850, 1,280,702lbs.; in 1851, 1,436,171 lbs,; in 1852, 1,229,349lbs.

	1840	1841
Residences in which this produce has been cultivated in 1840 and 1841, ...	20	20
Number of families destined for the labor,..	470,673	453,289
Trees which have yielded a crop, ...	216,193,894	236,085,600
Trees which have produced the average quantity of a picul of 125 lbs. Dutch, ...	280	248
Quantity of coffee furnished to the godowns in piculs,.....	706,258	877,444
Trees according to the reckoning made in the month of March, 1841 and 1842.	336,922,460	329,898,963

The comparative result of this table shows—1st. That, in the year 1841, coffee had been gathered from 20,000,000 more trees than the number in 1840, and that the crop had increased by 171,000 piculs. 2nd. That, in the month of March, 842, there were above 7 millions less of coffee trees than in 1840. This diminution is merely nominal, seeing that these trees have served to replace those which by their small produce have to be suppressed in the lowlands of the residency of Baylen. On the contrary, the increase of trees, planted from 1839 to 1840, amount to very nearly the same number, of 7 millions. 3rd. That, in the season of 1842, there was planted nearly 20 millions of plants; of which 12 millions are to serve to replace the old trees, and 8 millions are destined to extend this culture. It is calculated that this island will very soon be in a condition to produce a million of piculs, or 125 millions more of Dutch pounds of

coffee. Previous to 1830, Java scarcely exported as much as 40 millions of pounds.

Cultivation and Preparation of Coffee in Java.—For the following valuable details the public are indebted to M.de Munick,the inspector of the agricultural department, Batavia, as contributed to Simmond's "Colonial Magazine" (vol. xi. p. 46).

Soil and Situation.—Elevated lands are found to be those best suited for the growth of coffee in Java. Land situated between 1,000 and 4,000 feet above the level of the sea may be generally said to be adapted to the cultivation of coffee. It must not be taken for granted that all ground of less elevation is unsuited. Suitable ground is to be found lower down, but the cultivation on it is more difficult; the tree gives less fruit, and the plant is less durable. Valleys lying between high mountains are more especially fit for coffee plantations, because the soil which is washed down from the heights affords fresh food continually to the lowlands; the valleys themselves are moist, since the hills surrounding them attract the rain; and they are shut out from severe winds by the same protecting enclosure. The soils best suited to the successful growth of coffee may be classed as follows:—

Firstly.—Cleared forest lands, especially those in which the black, leafy, or vegetable mould is found to considerable depth. These are the richest grounds, and will support the coffee plant for many years, and they are also cultivated with the least trouble.

Secondly.—Dark brown soils, approaching to black, which, without having much clay in them, appear to the eye to have a mixture of coral. The greater the depth of this coral-like stratum, and of the reddish or deep yellowish soil, the better is the ground for coffee. This kind of land also has sufficient strength and substance to afford nourishment for many years to the plant; but it entails more trouble than the before mentioned soils, because the young plant does not so speedily strike root into it, and sometimes dies, so that provision has to be made against failures.

Thirdly.—Reddish and loose ground, such as is generally found in the neighbourhood of volcanic lands. This kind is frequently found well adapted for coffee; it flourishes on such land luxuriantly, but does not last long, as the ground possesses less strength and nourishing substance. (In the West Indies, from my own experience, I have found this to be one of the worst descriptions of soil. *P. L. S.*) By digging in different places we become better acquainted with the nature of the ground, but we may take it as a rule, that rich old forest land on which many large trees are found, and plains covered with heavy underwood, most frequently offer eligible sites for coffee plantations. Grounds in which loam is found, and stony soils, are unfit for coffee. But I do not mean by "stony soils" land on which many stones are lying, for on that very account it may be most suitable; but I mean land which shows a pebbly stratum just below the surface, or such as is of a porous, stony nature. In the choice of situation care must be taken to select that which is as much as possible protected against the south-east wind, because its dry influence is very injurious to the coffee plant, and also prevents the growth of the *Erythrina* (known here locally as the Dadap tree) which is so necessary for its shade. Flat grounds, or gentle declivities, are better than steep slopes; yet the latter can be well employed, if proper care is taken.

Cultivation.—After the ground has been cleared in the dry season—that is, after the bushes have been rooted out, the undergrowth burnt off, and the thickets removed—ploughing is commenced in September. When the ground has twice been deeply ploughed, the weeds and roots must be brought together with the rake and carefully burnt. The depth of the ploughing must be regulated by the nature of the ground. In all kinds of cultivation, deep ploughing is recommended, but in Java we ought not to plough deeper than the stratum of fertile soil, as a kind of subsoil may be brought uppermost injurious to plants, and which, before it can become fertile, must for a year at least have been exposed to the atmosphere. The ground having been turned up, should be left exposed for some days to throw off the vapor arising from it; and must then be again ploughed and cleared with the rake. After waiting for some days, it should be ploughed for the fourth and last time, and made as clean and friable as possible. In small plantations this is to be done with the spade, but on large estates the roller must be used. This roller consists of a heavy piece of round wood, eight or ten feet long, to which a pole is fastened in the middle to have oxen harnessed to it. It is drawn slowly over the ploughed land, and presses the clods to earth. To give it greater force the driver sits or stands upon it. Before the field has been properly ploughed and rolled in the above way, the middle of October will have arrived, and we then begin to open a path through the plantation from the highest to the lowest point, about two roods broad, and the whole of the land is then divided into separate parcels. Portioning off the estates into divisions of equal size is a system to be much recommended. By this means labor may be equally divided, superintended and inspected. Order and regularity, which are necessary in all things, are most especially required in cultivation on a large scale. The size of these parcels is regulated by the nature of the estate. On flat or gently declining land they may be greater than on steep grounds, because, in order to prevent the washing away of the soil on precipitous land, the water must be led off by trenches, which of themselves make

the divisions of land smaller. On flat ground the divisions may be each 625 square roods, each of which may contain, if planted—

	Trees.		Trees.
12 feet by 12 „	625	8 feet by 8	1406
10 „ 10	900	6 „ 6	2500

The distance between the coffee bushes cannot be definitely laid down, as it depends on the nature of the soil. On the most fertile forest lands twelve feet by twelve is a good distance. Only on low and meagre grounds, where the tree grows less luxuriantly and strong, can six feet by six be reckoned a proper distance. Between the divisions a path should be left, one rood in breadth. Along the middle paths and by the side of the divisions drains must be cut, the former two feet in breadth and depth, the latter one foot. The drains along the divisions must be cut in such a way as to conduct the rain-water to the larger drains which flank the middle paths. On precipitous ground, when the coffee is planted, small ridges should be raised between the rows, to prevent the rich earth from washing down in the heavy rains. The steeper the land is, the closer these ridges should be; and care should be taken to incline them, so as to break the descent, the direction of which they should in some degree follow. The first ridges may be made with the branches of the trees which have been felled, or with the rubbish cleared from the ground on the first raking of it.

Placing the pickets.—When the ground has been worked and divided in the above manner, the pickets are placed. These are slips of bamboo one-and-a-half to two feet long. First—two long canes (which do not stretch like string), each one hundred feet long, are marked off in feet according to the distance at which the planting is to take place; heavy stakes are made fast to each end of them, by which they can be well secured on the ground. At the places where they are marked off in feet, strings are fastened so tightly that they cannot be displaced; and then the canes are laid down and well fixed in the ground, one in the length and the other in the breadth. Picketing does not give much trouble; it ensures regular planting, and makes the daily inspection simple. The planting thus takes place in straight lines, which give an ornamental appearance, and afterwards renders the view over the whole plantation easy. At every place where a string has been tied, a picket is stuck in the ground; then the cane is removed to another place, and so on till all the estate is marked out by pickets. After the picketing, a hole is made with the spade at every mark; it should be a good foot broad and deep, and the earth inside should be made very fine and clear. The earth is now ready to receive the coffee plant, and the time has only to be waited for when the first rains fully begin.

Nurseries.—In the month of October, or earlier, if coffee trees are near at hand, nurseries must be prepared in the neighbourhood of the land about to be planted. This can be done in the ravines, or, if they are too far from the spot where the plants are wanted, pieces of ground most convenient can be selected. If the ravines are preferred, places must be chosen which are shaded by trees not prejudicial to the coffee plants. On ground where there are no trees, the nurseries may be covered, at the height of four feet, with leaves of jack (*Artocarpus integrifolia*), areca, or other palm trees, in a manner to admit the air. The ground made loose and fine, coffee plants newly opening, or seeds only, are planted or sown at a distance of four inches square; 500 square roods will in this way furnish 648,000 plants, which are sufficient for an estate of 300,000 trees. Transplanting from nurseries is absolutely necessary in coffee cultivation, and the trouble it costs is always doubly repaid. Having a choice of plants, a person can be convinced he has taken none but healthy trees, and he proceeds therefore with a confidence of success. After the first year, all failures having been nearly replaced, the estate is fully planted, the trees are of regular growth, and no useless clearing is required — a thing which is always necessary in irregular plantations. It is easy also to pick the berries from the trees which are planted with regularity; the work goes on smoothly; and when the estate has lived its time, it may be abandoned altogether, without leaving patches of living trees here and there, which renders superintendence so very difficult. There should always be a plentiful supply of plants, to give an ample choice and to make up for failures. When plants are placed in the nurseries, they should not have more than two offshoots, or leaves, above each other; and when the ball plants are transplanted, they should not be higher than a foot, as large plants always give meagre trees. At the end of November or beginning of December, if the nurseries are kept free from weeds, and, if necessary, occasionally watered, the plants will be about a foot high, and will have put forth 4 or 5 leaves; they are then just fit to be transplanted. Then the ground is cloven with the spade, at a distance of an inch and a half round the stem of the plant, to about three inches deep; the plant, with the ball of the earth adhering to it, is carefully lifted out of the ground, and the ball is wrapped in a jack, plantain, or other leaf, and tied to prevent the earth falling of; but, before the plants are thus taken from the ground, it must be moistened to make the earth adhesive.

Planting the coffee trees.—The plants, which, after the above operation are called "ball plants," are then placed in a bamboo wicker frame, and are carefully carried by two men to the place where they are to be put into the ground. They are then taken out of the frame and placed in the holes next to the

pickets. The pickets are removed, and the plant is fixed upright; the leaf surrounding the ball is made loose, but not taken away; the planter presses the plant down with his hand and fills up the hole with fine loose earth, and the business of planting the coffee tree is finished.

Planting the Dadap trees.—This is a species of Erythrina, probably *E. indica* or *E. arborescens*; that used for the purpose in the West Indies is *E. Corolladendrum*. In Java, as soon as the coffee is planted, the operation of planting the dadap tree is commenced. The best sort of dadap comes from Serp or Mienyak; it is smooth and broad-leaved, and shoots up quickly. Thick young stems are chosen, about three feet long, and the lower part is pointed off. If the dadap is moist or juicy, it should be cut twenty-four hours before it is planted. The dadap is planted uniformly by the measuring cane in the same way as the coffee itself. Between every two rows of coffee one of dadap is planted, not on a line with the coffee plants, but alternately with them; thus, if the coffee is eight feet by eight, the dadap is sixteen by sixteen. The dadap is planted to the depth of a foot, with somewhat of a westerly inclination, in order that the morning sun may fall on a large surface of the stick. The ground must be stiffly trodden round the bottom of the stem, and the upper part of it should have some kind of leaf tightly bound around it to prevent the sap from escaping. When the coffee and dadap plants have thus been put out, every fifth day the young plantation should be carefully inspected, and a picket placed wherever there is a failure, as a mark to the planter that a new plant is there required. This operation of replacing failures is carried on all through the wet season, and the dadaps which have not succeeded are at the same time changed.

Keeping up the estate.—In the first six months of the planting, the estate should be cleaned each fortnight with the hoe; the ground being well moved and the weeds taken out. Those weeds which are too close to the plants to be removed in this manner, must be pulled out with the hand. When the plantation is thus wholly or partially cleaned the earth must be taken off the weeds, and they must be collected and thrown on the pathways. The weeding in this manner gives at first a great deal of trouble, but it is most advantageous in the long run, as the weeds are thus easily kept down. Great care must be taken to do away with an old custom of burying the weeds in large holes on the estates. It conduces to bad and slovenly habits, such as cutting off the tops of the weeds by wholesale, and thus giving the plantation an appearance of cleanliness, whilst it, in fact, is as dirty as ever. This is soon discovered by the weeds showing themselves again above ground in a very few days, and even if they rot under ground, they breed insects which are very hurtful to the bushes, and the seeds vegetate. After the first six months, this weeding will be sufficient if it takes place once a month, but this must be persevered in till the third year, when there may be a much greatee interval between the weeding. When the trees ar coming to full growth, the hoe should be less frequently used in cleaning; the hand must be used to the full extent to which the branches reach, as the roots of the tree spread to a like distance, and if they are injured the growth of the tree is prejudiced. The well-being of an estate chiefly depends on frequent cleaning of the plantation in the beginning. The idea of some persons that cleaning in the dry season is of little consequence, must be given up, as it is principally at that very time that it is extremely profitable to remove and clear the ground round the trees in their growth. In the first place, this destroys the weeds which take the nourishment away from the trees: secondly, the ground is rendered more open to receive the slight showers and dews which moisten it, and to benefit by the influence of the air; the roots are thus considerably refreshed. The dew falling on ground which has been recently moved, penetrates at once into it, and does good to the plant; but if it falls on the weeds, the first rays of the sun absorb it, and deprive the tree of this source of refreshment. The dadap is to be taken care of whilst clearing goes on; it must be cropped so as to cause it to grow upright, and to throw as much shade as possible on the coffee without pressing upon it. In warm fertile ground, where the coffee plant grows rapidly, the trees should be topped in the third year; but this should be done sparingly, and as a general measure it is not to be recommended; it should be resorted to only as a means to prevent the too rapid growth of the tree, or its running up to a point. Topping and taking off suckers are both necessary on meagre soils, where the trees run much to wood; and it prevents the trees being injured in the picking season, which often occurs without this precaution. The top or middle stem is broken off at a height of six or seven feet, but care must be taken not to tear the tree; when the top shoots out again it must be cropped a second time, and it is seldom necessary to do this more than twice. The cropping causes the tree to shoot out in breadth, and to push forth a greater number of sprigs, and good strong ones.

Picking Coffee.—When the estate becomes productive, it must in the picking season, just before the work begins, be kept exceedingly clear of weeds, and be even swept clean with brooms, in order that the berries which fall off may be gathered up. The picking should take place under proper superintendence, the trees be picked row by row, and care taken that each berry is plucked off separately, and not a heap together, by which the trees are torn and the first off-shoots prevented. In picking high trees, light ladders

should be used, made out of two or three bamboos tied together.

Customary preparation of the berry in the pulp.—When the coffee is picked and brought into the village, it is piled up in a heap in the open air, and left in that manner for twenty-four hours. Thus heaped up it gets warm, and this creates a certain fermentation of the juice which is in the berry. That fermentation promotes the drying and loosens the silvery pellicle which is attached to the bean inside the parchment, and which cannot be entirely got rid of in any other way. Coffee which still retains that pellicle is called in trade "grey coffee," and is lower priced than good clean sorts. After the fermentation, the coffee is spread out in rather thick layers, and turned over twice a day. If it rains during this first spreading out, the coffee does not require to be sheltered, as the washing causes the juicy substance to evaporate, and this accelerates the drying afterwards. In proportion as the coffee becomes dryer, the thickness of the layer must be reduced, and the turning over must be more frequent till the coffee is quite dry outside and the pulp has become hard. Then the coffee is laid out on drying floors, which can be easily and speedily covered in rainy or damp weather, and is dried by the powerful heat of the sun. This system of drying in the pulp requires six weeks or two months, as it is advisable not to be over hasty with drying. When the coffee is entirely dry, it is either at once pounded or placed in the stores to await that operation. In order to know if the coffee be sufficiently dry, take a handful of it and shut your hand close; shake it to your ear, and listen if the beans rattle freely in the pulp. Or try them by biting the berry, and see if the bean and pulp are both brittle and crisp, which shows that the fruit is dry enough.

Preparation of the coffee in the parchment, or the West India system.—Only sound and fully ripe beans can be prepared in the West India manner. In picking, therefore, all unripe, green, or unsound beans must be taken away to dry in the pulp. As soon as the coffee is brought in, it must be pulped. This operation is performed by means of small peeling mills. These mills consist of two horizontal wooden cylinders rubbing on a plank; they are covered with hoop-iron, and set in motion by a water-wheel. The coffee is driven under the cylinder, and kept constantly moist; by being turned through the mill, the pulp is so bruised that the bean in the parchment falls from it into the bamboo open frame, which is placed in front of the mill. The coffee is then pressed with the hand, and falls through the frame into a basket. The pulp, and beans not rid of the pulp, remain on the frame; the first is cleared away, the rest passes a second time into the mill, and this operation is continued till all the coffee is stripped of the pulp, and the parchment beans are in the basket. When the parchment coffee is thus separated from the outer skin, it is thrown into the washing troughs, and remains there for twenty-four hours; this drains from it the slimy substance adhering to it. After being thus steeped, it is washed with pure water two or three times in the basket, so that it becomes quite free from slimy matter. The parchment coffee is then spread out on drying frames, and exposed for six or eight days to the heat of the sun, till the outside is perfectly dry. To do this equally it must be stirred about every hour. These frames, which serve also to dry the coffee in the pulp, are made as follows:—A bamboo roof is set up, resting on four wooden pillars, and sloping considerably; it is covered closely with reeds; its length is ten feet, its breadth six feet; the pillars are from nine to ten feet high; a wooden framework is attached to this, about thirty feet long, or three times the length of the space covered by the roof. On this frame are brought out three platforms, one above the other, which are pushed out by means of little rollers, under them; they are ten feet long by six broad, and six inches deep. The borders are of wood, and the bottom of platted bamboo. In rainy weather, or when the drying cannot go on, the three platforms are pushed under the covered space. These drying places are set up near the overseer's dwelling, where they stand free, and are not shaded by trees or buildings. After this first drying on platforms, the parchment coffee is again dried inside the house, and bamboo huts are for this purpose erected on each side of the outhouse of the planters. These huts have trays, divided into two or three compartments, one above the other, to keep the coffee separate, according to the time of its having been picked. The parchment coffee is spread out as thin as possible, and turned over with a small wooden rake every hour. In proportion to the dryness of the weather, from one to two months are required to dry the coffee fully. In drying inside the houses, the greatest care must be taken to prevent heating the coffee; this is the great object of the West Indian system, as such heating is very prejudicial. On this account the huts in which the platforms are placed must be very airy, so that the wind may have good play among the trays, on which the coffee must be thinly spread and frequently turned.

Pounding.—Coffee in the pulp, as well as that in the parchment, must, before being pounded, be exposed for some hours to the sun to make it crisp and hard; but it must be allowed to cool again before the pounding begins, or the beans will be liable to be broken. The pounding is done in small baskets of a conical form, two feet high, at the top eighteen inches in diameter, and at the bottom one foot. These baskets are, up to one-third of their height, thickly woven round with coir and fastened on the ground between four thick bamboo poles, and with the bottom

half an inch in the ground itself. The coffee is pounded by small quantities at a time with light wooden pestles; the baskets must not be more than half full. When the coffee is sufficiently pounded, the basket is lifted from between the poles and the beans are thrown into sieves, on which it is cleaned from skin, and white, black, or broken beans. According to the West Indian system, the coffee must now be instantly put in bags, to preserve its greenish colour, which is very peculiar. If the green coffee is not instantly sent to the packing stores to be bagged, it must be put up in a very dry place, and be turned over once every day, to prevent heating, which damps and discolors the berry.

Celebes.—Coffee is grown to some extent in Celebes—the average crop being from 10,000 to 12,000 piculs of 133 English pounds. The production has rather fallen off than increased during the last few years. The whole of the coffee grown must be delivered by the inhabitants to the government exclusively, at twelve copper florins per picul. It is much prized in the Netherlands, and maintains a higher price in the market than the best Java coffee. As the treatment of the product in Java differs wholly from that which is in vogue in Celebes, and this, in our eyes, is much inferior, I know not whether the higher price is ascribable to the name, or to an intrinsic superiority in quality. It is certain that this cultivation is susceptible of much improvement, and might be advanced to a much higher condition. From tables given by M. Spreeuwenberg ("Journal of the Indian Archipelago," vol. ii. p. 829) of the quantity of coffee delivered from each district of this island, for the years 1838 to 1842, it appears that the average annual delivery of coffee was 1,288,118 lbs. Of the production of Sumatra I have no details, but a very fair proportion is grown there—about five million pounds. *Aden*, alias *Mocha* coffee, is, along with the other coffees of the Red Sea, sent first to Bombay by Arab ships, where it is "garbelled," or picked, previously to its being exported to England. An excellent sample of coffee, apparently of the Barbera (Abyssinia) variety, was contributed to the Great Exhibition from Norfolk Island. It was of good color, well adapted for roasting, and a most desirable novelty from that quarter. Dr. Gardner, of Ceylon, has taken out a patent for preparing the coffee leaf in a manner to afford a beverage like tea, that is, by infusion, "forming an agreeable refreshing and nutritive article of diet." An infusion of the coffee-leaf has long been an article of universal consumption amongst the natives of parts of Sumatra; wherever the coffee is grown, the leaf has become one of the necessaries of life, which the natives regard as indispensable. The coffee-plant, in a congenial soil and climate, exhibits great luxuriance in its foliage, throwing out abundance of suckers and lateral stems, especially when from any cause the main stem is thrown out of the perpendicular, to which it is very liable from its great superincumbent weight compared with the hold of its root in the ground. The native planters, availing themselves of this propensity, often give this plant a considerable inclination, not only to increase the foliage, but to obtain new fruit-bearing stems, when the old ones become unproductive. It is also found desirable to limit the height of the plant by lopping off the top to increase the produce, and facilitate the collecting it, and fresh sprouts in abundance are the certain consequence. There are so many causes of the development of a vegetation which becomes injurious to the quantity of the fruit or berry unless removed; and when the superabundant foliage can be converted into an article of consumption, as hitherto the case in Sumatra, the culture must become the more profitable; and it is clearly the interest of the planters of Ceylon to respond to the call of Dr. Gardner, and by supplying the leaf on reasonable terms, to assist in creating a demand for an article they have in abundance, and which for the want of that demand is of no value to them. It ought to be mentioned also, that the leaves which become ripe and yellow on the tree and fall off in the course of nature, contain the largest portion of extract, and make the richest infusion; and I have no doubt, should the coffee leaf ever come into general use, the ripe leaf will be collected with as much care as the ripe fruit. The mode of the preparation by the natives is this, The ends of the branches and suckers, with the leaves on, are taken from the tree and broken into lengths of from twelve to eighteen inches. These are arranged in the split of a stick or small bamboo, side by side, forming a truss in such a manner, that the leaves all appear on one side, and the stalk on the other, the object of which is to secure equal roasting, the stalks being thus exposed to the fire together, and the leaves together. The slit being tied up in two or three places, and a part of the stick or bamboo left as a handle, the truss is held over a fire without smoke, and kept moving about, so as to roast the whole equally, without burning, on the success of which operation the quality and flavor of the article must depend. When successfully roasted the raw vegetable taste is entirely dissipated, which is not the case if insufficiently done. When singed or overdone, the extract is destroyed and the aroma lost. When the fire is smoky, the flavor varies with the nature of the smoke. The stalks are roasted equally with the leaves, and are said to add fully as much to the strength of the infusion. By roasting, the whole becomes brittle, and is reduced to a coarse powder by rubbing between the hands. In this state it is ready for use, and the general mode of preparing the beverage is by infusion, as in the case of com-

mon tea. That it would soon become a most valuable article of diet amongst the laboring classes, and on ship-board particularly, if once brought into use, there can be no doubt. The coffee-tree can be grown to advantage for the leaf in the lowlands of every tropical country, where the soil is sufficiently fertile, whilst it requires a different soil and climate to produce the fruit. (Correspondent of the Singapore *Free Press*, December, 1852.) Dr. Hooker, in the Jury Reports, observes upon the prepared coffee leaves, submitted by Dr. Gardner, of Ceylon, to be used as tea leaves, that they are worthy of notice as affording a really palatable drink when infused as tea is; more so, perhaps, than coffee is to the uninitiated. That this preparation contains a considerable amount of the nutritious principles of coffee is evident from the analysis; but as the leaves can only be collected in a good state at the expense of the coffee bush, it is doubtful whether the coffee produced by the berries be not, after all, the cheapest, as it certainly is the best.—*Simmonds' Comm. Products.* Coffee, originally an article of Eastern growth alone, became a product of considerable importance and value to England in her West India Islands, where, and in Java, the bulk of the then Coffee produce of the world was raised. The Dutch, at all times anxious to encourage agricultural and commercial progress in their Colonial possessions, though not always adopting the most enlightened mode of effecting the object, shewed not a little anxiety to foster, by every means in their power, the growth of this favorite berry. The Dutch Governors of Ceylon had, from their earliest possession of that fertile island, endeavoured to foster the production of coffee amongst the Singhalese villagers, by offering to take the berry from them at certain fixed rates, in payment of tithes and taxes. In spite of the constant endeavours to promote this cultivation, the Dutch Governors do not appear to have met with much success: for on the capture of Colombo by the British at the end of the last century, the total produce of the island amounted to not more than a few thousand bags. In a paper drawn up by an ex-official of the local Dutch Government, for the information of Sir Alexander Johnstone, we learn that the coffee of Ceylon was considered superior to that of Java or Bourbon, and approached more nearly to that of Mocha, whence the first plants were brought. It was matter of complaint that the Singhalese did not attend to its culture, but contented themselves with picking up the fruit as it fell from the trees in their wild state, which consequently produced but half the quantity of those in other places. The same "Memoir" states that Ceylon did not yield more than 25,000 pounds weight of coffee, though it was deemed capable of producing ten times that quantity under the supervision of experienced hands. We have lived to see it export in one year 5,000,000 cwts. Between the years 1830 and 1835, the coffee produce of the West India Colonies had fallen below the annual consumption of Great Britain, and in the latter year it was actually seven millions of pounds short of the quantity required. Necessity then compelled the Home Legislature to do an act of bare justice to British territories in the east, as a rate of import duty similar to that levied on the article from the West Indies, viz., six pence a pound, in place of nine pence, which it had previously been subject to, and which foreign coffee still had to pay on importation into Great Britain. The capabilities of Ceylon as a coffee producing country attracted the attention of the then Governor, Sir Edward Barnes, who was soon followed in his experiments by a few enterprising civilians and merchants. In 1837 several plantations were formed, which in a year or two gave indisputable signs of success. Prices rose at home, in consequence of consumption outstripping production, and when in 1842 an additional penny protection in the import duty was accorded British Colonial coffee over foreign, Ceylon rose rapidly into importance. The rush to the jungles of Ceylon at that time was, on a reduced scale, what the rush to the Diggings was in 1851. The following list of Crown Lands sold for the purpose of coffee planting at that period will bear witness to the eagerness with which capitalists and speculators entered this new field of Colonial industry:—

In	1837	the Government sold	3,661 Acres.
,,	1838	.....	10,401 ,,
,,	1839	....	9,570 ,,
,,	1840	....	42,841 ,,
,,	1841	....	78,685 ,,
,,	1842	....	48,533 ,,
,,	1843	....	58,336 ,,
,,	1844	....	20,415 ,,
,,	1845	....	19,062 ,,

The disasters of the years 1847 and 1848 are still fresh in the recollection of our readers. Ceylon planters felt the shock, and for a time were unable to stand the effects of low prices and ruined credit. During the coffee panic a few men of experience, having both capital and confidence, became the purchasers of estates at almost nominal figures. Plantations in full bearing—though overgrown with low jungle, were sold for less than the original cost of the land, many of them too with extensive works upon them erected at a heavy outlay. Two estates in Badulla, of 350 acres of three-years-old coffee, and which had cost £10,000, were sold for £350. Another plantation in the Dolosbagie district of 100 acres was sold for £105; having cost the proprietor £4,000. The Hindogalla estate had cost £15,000, but in 1849 realised only £500. The following statement shews the gradual but marked effect, first of want of cultivation, and

afterwards of care and skill in the management of the Ceylon estates. Coffee shipped from Ceylon during the following seasons:—

1848-49	Plantation Coffee.....	210,633
	Native ditto.....	121,215
		331,848
1849-50	Plantation Coffee.....	230,866
	Native ditto.....	99,071
		329,937
1850-51	Plantation Coffee.....	197,636
	Native ditto.....	90,274
		287,910
1851-52	Plantation Coffee.....	155,386
	Native ditto.....	152,621
		308,007
1852-53	Plantation Coffee.....	208,658
	Native ditto.....	115,451
		324,109

From this period the production of this island has continued to progress steadily, until in last year, the crop amounted to Cwts. 500,000, the chief increase being in the yield of plantation crops, arising partly from the formation of new estates, but principally the effect of skilful cultivation and the liberal application of manures. The author of "Coffee planting in Ceylon" tells us in regard to manuring on Coffee estates that "there are many difficulties to surmount in this "operation, owing to the localities of coffee plantations, though there can be no doubt that as "facilities are discovered in practice, the returns "obtained from plantations will richly repay all "this by a high standard of bearing, to which "we have been hitherto strangers. Cattle "manuring is the most generally available; the "cattle being stall-fed on guinea grass, planted "where the elevation of the plantation will permit it, or on Mauritius grass, which is planted "in the ravines amongst the coffee; thus at the "same time yielding a profit, and keeping weeds "out of places where they are apt to grow. "Pigs are also kept, and the pulps of the coffee "are added to the fertilizing mass; indeed, "rotting wood, weeds, burned Dolomite, and "anything which will produce ammonia, is now "taken care of on the estate. The economical "application of the enriching compost requires "it to be carried out by hand, and each laborer is "made to take out a basket as he goes to his "work, which a few men are employed afterwards, with mamoties, or forks, in burying "around the roots of the trees. The whole of "an estate has only in one instance within our "knowledge been manured at one time, and it is "seldom required. In a few years we expect to "see manuring so systematically managed, that "every part of the plantation will be brought "under its operation every second or third year, "and on this we base our expectation of a continued and increasing production from the estates already formed, far exceeding any returns we have hitherto seen. The estate which "was wholly manured, without limit as to expense, has amply returned the outlay by a "production of about 20 cwt. to the acre; lime, "cattle manure, and mould from the neighbouring forest, were used in a compost, and the "soil turned up every where round the plants "to apply it." Page 52. Amongst the many improvements introduced into Ceylon cultivation during the last few years, may be mentioned a magnificent set of water-works, erected by the late Mr. Morton, and his partner Mr. Tytler in the Vale of Doombera, for irrigating the Rajawella estate from the Mahavilla Ganga. The plantation to be thus watered contains about seven hundred acres of coffee: the land is fertile in the extreme, but subject to frequent severe droughts, which by means of this mechanical contrivance will no longer be feared. The works are completed, and were tried a short time since with perfect success: and there is no doubt but that the outlay will soon be amply repaid in heavier crops. At the present moment there are at least thirty establishments in Colombo for the preparation and shipment of coffee, the greater portion of which goes home in casks. The number of persons thus employed, from the reception of the berry from the estate in the damp "parchment skin," to the final shipment of the cured bean, cannot be fewer than twenty thousand, of whom by far the larger number are women. Such then has been the career of Ceylon in the production of coffee. The Dutch, whilst accomplishing so little in this island, where so much has since been done, met with more success in Java, which to this day is one of the principal coffee-producing countries of the east. The cultivation of the plant was commenced in January 1728 by the Governor-General of Batavia, who spared no pains to induce the inhabitants of the rural districts to propagate the berry and prepare it for market. By dint of a lavish outlay in the first instance, and afterwards by means of immunities and premiums, aided by climate and soil admirably adapted to the culture, the Dutch Government succeeded in their object, and rendered the export of coffee from Java a most valuable branch of the local trade. From the early period we have indicated to the end of the last century, the progress made was not nearly so rapid as during the last thirty years, when the produce of this island has reached nearly a million hundredweights. M. Munnick, the Inspector General of Agriculture in Batavia, in a paper on the subject, states that coffee was produced in twenty differ-

ent departments of the island, giving occupation to nearly half a million of persons, and that there were ten years ago 350 millions of trees in the island. The soil and localities selected for coffee cultivation in Java appear to be precisely those chosen in Ceylon: fine loamy forest land situated on the slopes of mountain ranges, at an altitude ranging between one and four thousand feet. The modes of culture followed in the islands differ very materially. Whilst in Ceylon nothing in the first instance is needed beyond felling and burning the forest trees, and planting the young coffee seedlings at regular intervals in spacious holes between the huge stumps left to rot in the ground;—in Java, after the ground has been thoroughly cleared from jungle and weeds, the whole has to be ploughed three or four times, and eventually rolled or raked smooth previous to being planted. Shade, which has been for many years quite abandoned on coffee plantations in Ceylon, is stoutly maintained in Java; the same care in the after cleansing of the planted land is observed in both islands. But whilst the Ceylon planters have availed themselves of every possible improvement in the cropping and growing of their coffee, by the use of valuable machinery and carefully arranged stores, the Javanese grower is content with the rude contrivances which satisfied his ancestors in 1723. Coffee is produced in Sumatra and Celebes, the former exporting about 50,000 cwts. and the latter about 15,000 cwts. annually. The produce of Celebes is very highly esteemed in Holland, where it commands a better price than the finest Java sorts; this too in spite of the rudest culture, and a mode of preparation of the berry far more primitive than that adopted in Batavia. The entire quantity, which appears to have remained stationary for some years past, is taken by the Government from those who grow it at certain fixed rates, and by them shipped to Europe. A small production of this berry takes place on the elevated lands of the eastern coast of Siam, amounting until recently to not more than a thousand cwts. yearly. The quality has been approved in the English and some of the continental markets, where it is thought to approach more nearly than any other description to the Mocha berry, in appearance and flavor. The cultivation of the Siamese plant is being gradually extended, and now that the rulers of that country are pursuing a liberal and enlightened policy, in regard to internal industry and improvement, and external trade, it is not too much to expect a considerable increase in this article of its produce. Penang supplies a small quantity of rather inferior coffee to the markets of the world, but there is no reason to doubt its capability of furnishing a much larger quantity of a good article, if sufficient attention were bestowed upon the cultivation. The islands of Bourbon and Mauritius furnish a considerable quantity yearly, especially the former; the bulk of its crop being shipped to France, where, however, it is being rapidly supplanted by the produce of Costa Rica and Ceylon. Of the coffee culture of the Tenasserim provinces we are without any reliable data. Mysore has for a long period furnished an article which has gradually grown into public favor in England at a medium value. The coffee of Travancore sells in the London market at about the rate of ordinary Ceylon plantation kinds, but the produce of the Neilgherries bids fair to rival some of the better qualities of that coffee. It is now about twelve years since the slopes of the Neilgherries first attracted attention as suitable for the growth of coffee. The altitude, the soil and the climate were highly reported upon by such of the Ceylon planters as visited the early clearings about ten years since. Labor is most abundant and cheap, and the land, although not to be bought, is obtainable for long tenures on very favorable terms. Some of the sites selected turned out unfortunate, as might have been expected, in the first instance; but experience has now enabled the planters to proceed with far greater certainty, and the result of late gatherings shews that success is all but complete. Here, as in Ceylon, the planters have the choice of a great variety of altitudes and aspects, so that if a due supply of moisture at the periods of blossoming and ripening can only be secured, they have little to fear. Transport of crops from the estates to the sea-board has been a source of some difficulty, but even this is gradually disappearing, and at the present moment we are assured the planters of this part of the Peninsula can place their produce on board ship at a less cost than can be done in Ceylon, where the transport of coffee from the Central Province plantations to Colombo averages a higher rate per cwt. than the freight to London or Liverpool. In Lower Bengal the cultivation of the coffee plant has within the last few years made some progress, and contrary to the expectation of very many who were entitled to speak on the subject, it has proceeded with highly satisfactory results. In all the coffee-producing countries of the east, and in most of those in the west, the berry is produced on land more or less elevated, at an altitude rarely less than one thousand feet, the average being certainly two thousand feet above the sea-level. There is a little coffee produced in one district of Ceylon where the altitude does not exceed nine hundred feet, but this is a very rare exception to the general rule. The two localities in Bengal which have thus far proved favorable to this cultivation, are not more than two hundred feet above the level of the sea: the one at a distance of about two hundred miles to the north west of Calcutta, the other scarcely more than eighty miles from the capital in an easterly direction. This latter, planted under the eye of a gentleman practically acquainted with the Ceylon and West India

modes of culture, consists of a fine vegetable mould, on which trees of large growth have been found, together with a rich vegetation of jungle plants. The system pursued has been that of the Ceylon planters, with one or two trifling modifications. The estate, which is of about one hundred and twenty planted acres in extent, contains some thirty or forty acres of plants now in their third year, wearing a most luxuriant appearance, and bearing what promises to be a heavy crop. These plants gave a small first picking in their second year, a result of which we have never heard a parallel. The berry attains a medium size, short but well-grown, with a good proportion of pea-berry. A few sample bags were shipped during last season, and being favorably reported upon, realized fifty-four shillings in Mincing Lane. The proprietor estimates that he can place his crop on board ship at Calcutta, not costing him more than six shillings per cwt.; but this must of course depend mainly on the average extent of future crops, to pronounce an opinion on which would, we think, be rather premature at the present time. It is true the plantation is well situated for irrigation, being close to the banks of a fine river, which advantage may in a great measure compensate for occasional insufficiency of rain at critical periods; but it remains to be seen if the forcing nature of the climate of Bengal will enable the coffee plant to yield full crops during a succession of years. At any rate the prospects are most encouraging for the proprietors, who can well afford to have a certain proportion of light coffee, whilst the efficacy of manure added to irrigation has yet to be tested in this locality. The plantation formed in the Hazarebaugh district, at a greater distance from Calcutta, promises equally well as regards quality. The distance to be traversed with the crop is greater, but it is within reach of the railway, and in a district where labor is at once easily obtained and cheap: it is situated at a somewhat greater elevation than the first-named estate, and the berry gives promise of a bolder sample. It is now in its second year, and giving a maiden crop. Whether other localities in British India may be found more suitable for the growth of coffee, and at not too great a distance from a port of shipment, has yet to be seen. There is land enough and labor enough in many directions; it has but to be seen if India can produce coffee with more advantage than other commercial staples. Without a doubt there are abundant means of remunerative employment for all her people and all her land, if justice be done to the country by greater security being afforded to capital, and if more ready means of communication be found between the plains of the South and the Delta of the North-west. It may interest many of our readers to learn the present actual yield of the coffee-producing countries of the world, and on referring to the statement below, to remember that at the close of the last century, the only varieties known in the London market were those from Jamaica, Grenada and Mocha, the consumption of the United Kingdom being at that time, about one million of pounds annually. On the continent of Europe at the same period, the varieties from Mocha, Brazil, Bourbon, and Netherlands India, were alone used. The following is about the present production of coffee throughout the world:—

IN THE WEST.

Brazils,	300	millions of lbs.
La Guayra and Porto Cabello,	30	„
St. Domingo,	32	„
Cuba and Porto Rico,	25	„
Costa Rica,	10	„
British West Indies,	6	„
French and Dutch ditto.	6	„
		409

IN THE EAST.

Java,	140	millions of lbs
Ceylon	56	„
Indian Peninsula,	6	„
Sumatra,	5	„
Arabia,	3	„
Philippine Islands,	3	„
Celebes and Siam	2	„
		215
Millions of lbs.		624

The present consumption of the world, excepting of course the countries of production, is stated to be as follows:—

	Millions of lbs.
United States and British America,	170
Holland and Belgium,	125
German Customs Union,	95
Other German States,	46
France,	33
Great Britain,	32
Sweden and Denmark,	20
Mediterranean Countries,	20
Spain and Portugal,	15
Switzerland	13
Russia	12
Australia and Cape of Good Hope,	6
	587

Cal. Rev. 1857, *p.* 107.

Dekhan. In gardens of the Deccan, this plant seldom exceeds nine or ten feet in height, plants are easily raised from fresh seed in a nursery bed where they may remain until they are one or two feet high, when they should be carefully removed to the situation where they are to remain for good, and placed at about twelve feet apart, they will thrive well in almost any good light soil; but require a certain amount of protection from the sun, the most favourable situation for a plantation is the side of a hill exposed to the east, as the plants suffer much from hot winds, the shade of plaintain trees offers a good protection to them. In the neighbourhood of Aurungabad, there are some coffee trees which have borne fruit in abundance in a garden enclosed on all sides, and which even in dry weather is moist from being shaded.

by a number of high cocoanut and sooparie trees and the whole further protected by surrounding buildings, from the dry winds during the greater part of the year.—*Riddell.*

Tenasserim. Coffee not inferior to the best from Mocha, has been raised at Tavoy, but the plants do not flourish after the fourth or fifth year.—*Mason.*

Madras. At the Madras Exhibition of 1855, many good samples of coffee were exhibited from various districts, and some of very superior quality from the virgin forest land of the Western ghauts —the cultivation of this plant is now extending greatly, and becoming of much importance. It has been pursued with great success by private individuals. Mr. Green of Munzeerabad exhibited a beautiful series of very fine and well picked coffees, including the pearl or pea berry, but the aroma was defective, as the samples had absorbed an effluvia from the oily wood of the boxes in which they were enclosed. The jury awarded a second class Medal. Mr. Cannan's coffee from Annoor in Mysore, Mr. Ouchterlony's from the Western slopes of the Neilgherry range below Naidoobettah, and Mr. Fischer's of the Shevaroy Hills in Salem district, were all of the best quality, and in the best condition. Mr. Fischer's sample tho' deficient in colour, was exceedingly carefully cured and prepared, and the beans being close and well formed, it was deemed worthy of honorable mention. Mr. Ouchterlony's sample was also very carefully prepared, and well cured; the bean is large, and remarkably well shaped, in this respect and in color this sample surpasses Mr. Fischer's. Mr. Cannan's coffee, however, excelled both in color and aroma, being in these respects unexceptionable; the bean is large, but more irregular in shape and size, than either of the other two. These two last were considered the best and worthy of second class Medals.—*M. E. J. R.*

Assam.—Mr. Bonynge spent fourteen years in the East, and describes a variety of coffee acclimated in a region so high above the ocean, that the tree bears well in a climate subject to pretty severe frosts —*Bonynge America, p.* 55.

Adulteration of Coffee.—The effects of this may be briefly summed up as follows: 1st. While in Britain, the consumption of all other articles, during the past few years has progressively increased with the increase of the population, coffee, during that period, has remained comparatively stationary, although, as is well known, the use of an article, under the name of coffee, is now much greater than formerly, especially amongst the members of the different temperance and total abstinence societies. 2nd. It has been ascertained that a much larger quantity of a substance called coffee is annually sold than passes through the custom-houses. 3rd. Chicory is cultivated in large quantities, in various parts of Britain, and as little chicory is retailed to the public under its own name, the inference is, that it is employed, and annually consumed, in the adulteration of coffee. The chief articles although many others are occasionally employed with which coffee is adulterated are, chicory, different kinds of corn as wheat, rye, and barley, potato, and beans. But to be employed, it is necessary that these substances, like the coffee-berry itself, should be roasted —that is that they should be partially charred, and so far reduced to the condition of charcoal, or carbon. We will now describe sufficient of the structure of each of these substances as will be necessary to enable us to detect the adulteration of coffee with any one or more of the above substances.

Structure of the Coffee-Berry.—Two parts are to be discriminated in the coffee-berry—the substance of the berry and the testa, or investment, by which it is surrounded. The berry, previous to roasting and even after it has been soaked for a long time in water, is hard and tough, in which respect it differs from all those substances which enter into the adulteration of coffee and which become softened by immersion in cold water, the hardness is even retained subsequently to the charring and is so great, that by this character alone the fragments of the ground and roasted coffee-berry may be readily distinguished from those of chicory. It consists of an assemblage of vesicles or cells of an angular form, which adhere, so firmly together that they break up into pieces rather than separate into distinct and perfect cells. The cavities of the cells include, in the form of little drops a considerable quantity of aromatic volatile oil, on the presence of which the fragrance and many of the active principles of the berry mainly depend. *The testa*, or investing membrane, presents a structure very distinct from that of the substance of the berry itself, and when once seen it cannot be confounded with any other tissue which has yet been observed entering into the adulteration of coffee. It is made up principally of elongated and adherent cells, forming a single layer and having oblique markings upon their surfaces; these cells rest upon another thin membrane which presents an indistinct fibrous structure.

Structure of Chicory Root.—Chicory is the root of the Cichorum intybus, a plant belonging to the natural order Cichoraceæ, which includes the Dandelion; and, as might be supposed, from the very dissimilar characters of roots and seeds, it differs very greatly in structure from the coffee-berry. In it also two parts require to be discriminated—cells and vessels. The chief bulk of the root is made up of little utricles or cells which are generally of an elongated form, but sometimes rounded and which unlike the cells of the coffee-berry separate from each other with great readiness and present appearances which when once observed cannot be mistaken. The

cells do not, like those of coffee, contain globules of essential oil, a fact of much importance. Running through the centre of the root in a longitudinal direction are bundles of vessels varying greatly in size, but all of the dotted or interrupted spiral kind. Now there is nothing analogous to these beautiful structures in the coffee-berry, or in the majority of the substances ordinarily employed in the adulteration of that article. Chicory, owing to the absence of essential oil, unlike coffee, readily imbibes water, and when immersed in that fluid it quickly becomes soft in which respect also it differs from the roasted coffee-berry.

Structure of the Farina of the Gramineæ.—Each grain of the different species of corn deprived of its investing tunics or husks consists of a network of cells the substance of which has been denominated cellulose and in each of which a variable number of starch granules is included. These starch granules differ in character in different plants, and this frequently even in species belonging to the same natural family, so that by their means it is often easy to name the particular species to which any given granule belongs. In the majority of the corn tribe, the granules are flattened and rounded discs, of moderate size, obscurely marked with concentric lines or rings; the starch granules of many species also possess other perfectly distinctive markings, and characters, of which in this place, it is not necessary to give a detailed description, as in a future report the starch of wheat, rye, oats, &c., will be fully described and accurately represented.

Structure of the Farina of the Leguminosæ.—The different species of beans and peas deprived of the seed-covering, possess a structure analogous to the grain of corn decorticated: that is each pea or bean consists of a reticulation of cells, the cavities of which are occupied with numerous starch granules. The cells differ, however, from those of the seeds of the Gramineæ in their stronger and stouter character, and particularly in the thickness of their parietes. The granules in the pea, bean and many other species of this tribe, are large, oval, sometimes reniform, and the central cavity is usually of an elongated shape, presenting the appearance of a furrow under the microscope. These also will be figured and further described at a future stage.

Structure of the Farina of the Potato.—Pure potato flour is seldom used in the adulteration of coffee, it being too expensive and otherwise not well adapted for the purpose: it is usually the whole potato which is employed and which is probably first boiled and then roasted. The general structure of the potato resembles, to some extent, that of the corn, pea, and bean already cursorily described. In the unboiled state the cells form a coherent reticulation, but after boiling, they readily separate from each other, and thus show that each is really a distinct and independent structure. The cells after boiling present a somewhat fibrous appearance, and are, of course, much larger than the starch granules, many of which are contained in each cell. The granules themselves, as seen in pure potato flour, are large, ovate, and beautifully marked with concentric rings, but in the boiled potato, they lose much of their form and beauty, and become, for the most part, mis-shappen and collapsed. The very different effects of the action of water on ground coffee and chicory afford, then, one useful and practical means of discriminating between genuine coffee and that adulterated with chicory. The natural colour thus produced does not, however, satisfy the trade, and a material is very extensively employed to heighten the tint and thus to hide the nature of the adulterations practised: this is called "the coffee-colorer." The specimens of this article which we have examined have consisted of burnt sugar, the great coloring properties of which are well known. From an examination of samples of the substances sold in London as coffee it appears,

1. That of thirty-four coffees, thirty-one were adulterated.

2. That chicory was present in thirty-one of the samples.

3. Roasted corn in twelve.

4. Beans and potato flower, each in one sample.

5. That in sixteen cases the adulteration consisted of chicory only.

6. That in the remaining fifteen samples, the adulteration consisted of chicory, and either roasted corn, beans, or potatoes.

7. That in many instances the quantity of coffee present was very small, while in others, it formed not more than one-fifth, fourth, third, half and so on, of the whole article. Chicory root is no substitute for coffee, as it completely wants the peculiar fragrance, and the invaluable stimulant qualities of that berry. The adulterations by means of roasted corn, beans, potato, and coffee-colorer, are altogether indefensible, since the only thing in common between these and coffee is the colour which they yield on infusion or decoction. Some years since roasted corn, principally rye, was largely sold and employed to make a beverage which by a fiction was dignified by the name of coffee: the chief argument, independent of price, urged in favor of it, was its supposed nutritive properties. When it is recollected that the starch of roasted corn is nearly all reduced to the condition of charcoal, it will at once be perceived that its nutritive qualities cannot be very great, and that a single mouthful of wholesome bread contains more nourishment than a dozen cups of beverage made from roasted corn. Although "roasted corn" is now no longer sold openly, yet, the grocer has not failed to avail himself of it for his own benefit, but to the great disadvantage of the public. The adulteration of

coffee by substances so cheap and, for the purpose to which they are applied, so worthless as this, is a gross fraud, requiring emphatic condemnation and when ascertained to be practised, meriting exposure and punishment. Thus every person in England who is desirous to have good coffee should never buy ground coffee, except of tradesmen of unquestionable integrity, but should procure the roasted berry. In chosing this, care should be taken to notice that it be not too dark, for if so, it has been too much roasted and some of its active properties have been injured or destroyed. It should be ground to rather a fine powder, as this, by setting free the essential oil contained in the cells, allows more readily of the action of water upon it. Immediately on being reduced to powder it should be placed in a tin canister. Lastly, an infusion and not a decoction of the berry should be made, as, during the process of boiling, the active principles, and especially the delicate aroma, are in part dissipated. By attending to these directions, not only will good coffee be obtained but " a heavy blow and great discouragement" inflicted on the adulterators of coffee. Above all, the coffee-drinker should never buy the coffee contained in canisters, for he may be assured that it is even more adulterated than other coffee, as it is necessary not only that the purchaser pay for the coffee, but also for the canister itself.—*Hassal, Food and its adulterations, page* 3.

(2770) COFFEE-TREE WOOD, (COFFEA ARABICA). The wood is of a light greenish-brown or dusky-yellow, with a bark externally resembling box-wood, but thicker and darker. The specimen I have is nearly as close-grained and hard as box-wood : it has no smell, and but little taste. The tree does not grow more than a few feet high, and it is cut down in the plantations to five or six feet and is not therefore useful in manufactures. The tree called Kentucky coffee-tree, or hardy bonduc, is very different from the common coffee, it forms a large tree called Gymnocladus canadensis. The wood is compact, of a rosy hue, and used by cabinet makers.—*Tredgold.*

(2771) COHUNE OIL, a product of the kernel of the " Attalea funifera," of Martius, a native palm tree of South America. It is something like the cocoanut, but is more oleaginous. Its introduction into Southern Asia merits attention.—*Seeman.*

(2772) COIR. Coir is one of the many products of the cocoa-nut palm Tree to which article, accordingly, we refer. Though in commerce, the Cocoanut is best known for the fibrous covering of its nuts which is so well known under the name of Coir, it also produces a downy fibre which is used to stop bleeding from wounds. This is altogether of a more delicate nature, and forms a kind of network, which is beautifully white, and even transparent, when young. It is thus seen at the bases of the young fronds ; but as these attain maturity, this natural matting becomes coarser, tough, and of a brownish colour. It may be stripped off the tree in large pieces, which are used both in India and Ceylon as strainers for palm wine or cocoa-nut oil, or for straining sago or arrow-root. Mr. Ellis describes it as " consisting of long and tough fibres which regularly diverge from both sides of the petiole of the leaf. Sometimes there appear to be two layers of fibres, which cross each other, and the whole is cemented with a still finer, fibrous and adhesive substance : the singular manner in which the fibres are attached to each other, causes this curious substance, woven in the loom of nature, to present to the eye a remarkable resemblance to cloth spun and woven by human ingenuity" (vol. i, p.53). This is very similar to the arrangement of the Ejoo fibre, but in which both coarse and fine fibre are intermixed. The husk or rind of the Cocoa is thick and full of fibres, which in their separated state are so will known by the names of Coir or Khair. In order to remove this husk, an iron spike, or sharp piece of hard wood, is fixed in the ground. The nut is then forced upon the point, which passes through the fibres, and thereby separates the rind from the shell. In this manner, Mr. Marshall says, a man can clear 1000 nuts daily. The husk, cut transversely, is frequently used for polishing furniture, scrubbing floors, and as a substitute for brushes and brooms. Mr. Robinson describes the method of making Coir in the Laccadives, as follows : " As the husk gets hard and woody if the fruit is allowed to become quite ripe, the proper time for cutting it is about the tenth month. If cut before this, the Coir is weak ; if later, it becomes coarse and hard, and more difficult to twist, and requires to be longer in the soaking pit, and thus becomes darker in colour. When cut, the husk is severed from the nut and thrown into soaking pits. These, in some of the islands, are merely holes in the sand, just within the influence of the salt water. Here they lie buried for a year, and are kept down by heaps of stones thrown over them to protect them from the ripple. In others, the soaking pits are fresh-water tanks behind the crest of coral. In these, the water not being changed becomes foul and dark coloured, which affects the colour of the Coir. When thoroughly soaked the fibrous parts are easily separated from the woody by beating. If taken out of the pits too early, it is difficult to free the Coir from impurities. If left in too long, the fibre is weakened, as is said to be the case also with that soaked in fresh water." These different modes are also practised in Ceylon. " At Calpentyra and the Akkara-pattoo, the natives separate the Coir by burying the husks along the border of the extensive salt-water lake, and when, after six months or more, they are dug out very clean, the fibres easily separate

from the cellular tissue of the husk. This mode of preparing the fibre prevents the offensive smell emanated by macerating the husk, so common along the road from Colombo to Matura" (Ondatjee). The Coir from the islands of Kadamat Kiltan, and Chetlat, in the Laccadives, is said to be of the best description. The manufacture into cordage of the Coir is entirely in the hands of the women of the Laccadives. When soaked sufficiently long, it is taken out of the pit and beaten with a heavy mallet. Subsequently, it is said to be rubbed with the hands until all the interstitial cellular substance is separated from the fibrous portion. "When quite clean it is arranged into a loose roving, preparatory to being twisted, which is done between the palms of the hands in a very ingenious way, so as to produce a yarn of two strands, at once. No mechanical aid, even of the rudest description, has yet found its way into these islands." (Robinson.) It is curious that in these islands, Coir is one of the chief commodities of barter for the necessaries of life, as rice, salt, tobacco, &c. The Coir is made up for their petty traffic in short *kale* of a mixed length and weight, and at the end of the year these are collected and made up into lengths, of 70 to 75 fathoms, as received by the Government. Mr. Robinson, in his 'Report on the Laccadives,' states that the difference in the quantity of Coir manufactured from a coast nut and from an island nut is very considerable. We may premise that forty Cocoa-nuts are said to yield 6 lb. of Coir in Ceylon, Mr. Robinson says: "Three large coast nuts will yield 1 lb. of Coir, measuring twenty-two fathoms: whereas, ten small, fine island nuts go to about 1 lb. of Coir—but this will measure thirty-five fathoms: 2 lb. of such yarn, measuring from 70 to 75 fathoms, are made up into sooties, of which there are fourteen to a bundle, averaging about a maund of 28 lb. A Mangalore candy of 560 lb. will thus be the produce of 5600 nuts, and should contain about 20,000 fathoms of yarn. The actual price of Coir received by the islanders, is about thirteen rupees per candy. The value of the Coir produce of a tree is calculated to be from two to two and a half annas; and that of the produce of one hundred trees, from fourteen to fifteen rupees. "The average value of the total raw produce of a tree bearing fruit, would then be seven annas to half a rupee; and that of a plot of one hundred trees, forty-five rupees." For the nuts which they export to the Malabar coast, they get from seven to ten rupees per thousand, or rather 1,100, as ten per cent. is always allowed for luck in these sales. The islanders export from 300,000 to 400,000 nuts annually. The natives bring their Coir to the coast, in March and April, which is then received into the Government godowns. Until the year 1820, all Coir was paid for at the rate of twenty-one rupees fourteen annas per Mangalore candy, or twenty-five rupees per Calicut candy of 640 lb. After that year, the Coir was divided into three classes. Since then, the average price paid for a Mangalore candy of Ameendevy and Kadamat Coir, has been twenty rupees and two annas (or twenty-three rupees per Calicut candy of 640 lb). But for the Kiltan and Chetlat Coir, which are the best, an average of twenty rupees twelve annas and seven pie, or twenty-three rupees twelve annas per Calicut candy, is paid. Up to A. D. 1825-26, the Bombay and Bengal Governments took almost the whole of the Coir brought from these Islands, and credited the Mangalore collectorate with twenty-five rupees per candy. The price has since fallen very much during the last twenty years. It has been frequently below the price paid to the islanders, and at best, has never yielded above twelve to twenty per cent. profit. The average imports of Coir have been from five hundred to six hundred candies. (Robinson.) Coir, besides its principal use as cordage, is much used in India in place of hair for stuffing mattresses, and is certainly preferable to those stuffed with ox-and cow-hair, which are still sent out to India. It is also employed for stuffing cushions for couches, and saddles. Dampier also mentions that the Spaniards in the South Seas make oakum to caulk their ships, from the husk of the Cocoa-nut, "which is more serviceable than that made of hemp; and they say it will never rot." He adds: "I have been told by Capt. Knox, who wrote the relation of Ceylon, that in some places of India they make a sort of coarse cloth of this husk of the Cocoa-nut, which is used for sails. I myself have seen coarse sail-cloth made of such a kind of substance." ('A Voyage round the World.') But this seems to be made from the fibrous substance found at the bottom of the leaves; for in Knox's 'Ceylon,' Suppl., p. 250, it is stated: "The filaments at the bottom of the stem may be manufactured into a coarse cloth called *gunny*, which is used for bags and similar purposes." From the details which we have given respecting the preparation, and other points connected with Coir, it is evidently a substance of considerable value; and though there is some difficulty both in separating and in twisting this fibre, it seems long to have been applied to useful purposes—as cordage for the boats and shipping of the East. Some of the boats even, in Ceylon and on the Coromandel coast, are composed of planks sown together with Coir yarn. So Sir J. Maundeville says in that island are ships without nails or bands, on account of the rocks of adamants (loadstones), &c." Though imported from the islands in the form of sinnet, it may be manufactured into cordage of any size and cables of various bulk. A quantity of hawsers and cables are now annually exported from Ceylon. The character of Coir

has long been established in the East, and is now well known in Europe as one of the best materials for cables, on account as well of its lightness as its elasticity combined with considerable strength. These are further valuable as being durable, and little affected even when wetted with salt water. Numerous instances have been related of ships furnished with cables of this light, buoyant, and elastic material, riding out a storm in security, while stronger-made, though less elastic ropes of other vessels have snapped in two, and even when chain cables have given way. Indeed, until chain cables were so largely introduced, most of the ships navigating the Indian seas were furnished with Coir cables. Mr. H. Dalrymple, Master-Attendant, &c., at Madras, states in one of his reports: "Cordage from good Coir is extensively used by vessels of all descriptions in India. In vessels of 600 tons it is commonly used for lower rigging. The yarns being tarred previous to its being laid up in Europe, are preferred for lanyards to the lower rigging." Though rough to handle, and not so neat-looking as hemp cordage for rigging, it is yet, when properly made sufficiently pliable, and being elastic, is well suited for running rigging where lightness is an advantage, as for the more lofty sails and sheets; but from its elasticity it is not considered so well adapted for standing rigging. Dr. Roxburgh, in his experiments, found that tan was not applicable, and it is sometimes stated that it is not capable of taking tar; but even in Dr. Roxburgh's time, tar had been successfully used in the Coir cables made at Calcutta. Mr. Hornby already mentioned, states, that he could make from the Cocoa-nut fibre (Coir), rope of every size up to a 14-inch cable; indeed that such has been made by the prisoners, and was then under trial by the Government Marine authorities. Some beautiful specimens of 8 inch rope were sent by Messrs. Harton, of Calcutta, to the Exhibition of 1851, in the form both of cold and of warm register rigging. The latter is well covered with tar. The comparative strength of Coir cordage is well known, but we may, nevertheless, mention, that in some experiments made by Dr. Wight, Coir cordage broke with 224 lb., when *Hibiscus cannabinus* bore only 190 lb., but the Moorva, 316 lb. It having been inferred, a few years ago, that instead of sending Russian Hemp and Europe-made cordage to Bombay, it would be practicable to make good cordage and cables there, as had long been the case at Calcutta. It was observed, in reply, that a good manufactory of Coir rope could no doubt be established there: as when a Mr. Rennie had his manufactory at Bancoot, several of the country ships used Coir for standing rigging. Also, that with good materials and machinery he manufactured cordage which superseded some of the imports from Europe; with the exception of buntlines and leechlines, which chafe against the sails, and for which, therefore, Coir will not answer. The largest ropes used there are for hawsers and for messengers: and of these, Coir hawsers are much employed in the port of Bombay. As it may be interesting to know the kinds of cordage chiefly employed in the East, as well as its weight and cost, we subjoin the following,

STATEMENT SHOWING THE COST OF EVERY DESCRIPTION OF COIR CORDAGE USED BY THE GOVERNMENT VESSELS, INCLUDING THE CHARGES FOR MANUFACTURE, ETC.

	No.	Ms.	Sr.		Co. Rs.	A.	P.
Coir Cable of 14 -inch,.....	1	44	15	at 6 1 11 per md.	271	9	1

" 2½ inch coil,	1	1	28	"	10	6	5
" 1½ inch coil,	1	0	28	"	4	4	6
" 1 -inch coil,	1	0	20	"	3	1	0

STATEMENT SHOWING THE VALUE AND WEIGHT OF A COIL OF COIR ROPE OF THE DIFFERENT DESCRIPTIONS MADE IN BOMBAY AND BENGAL.

Description.	Bengal. Weight. Ct qr lb	Bengal. Value. Rs.	Bombay. Weight. Ct qr lb.	Bombay. Value. Rs.	Difference. Rs.
1 Coir Cable of 14 in.	32 2 4	—	32 1 8	—	—
" 8 in	12 0 21	—	11 1 10	—	—
" 7 in	9 1 10	—	10 1 9	—	—
" 6 in.	6 3 24	—	7 1 0	—	—
" 5 in.	4 0 27	—	4 0 0	—	—
1 coil Coir Rope 4½ in	3 3 2	—	3 2 16	—	—
" 4 in.	2 2 27	—	3 0 22	—	—
" 3½ in.	2 0 15	—	2 2 20	—	—
" 3 in	1 2 20	—	2 0 0	—	—
" 2½ in.	1 0 27	—	1 1 25	—	—
" 1½ in	0 2 1	—	0 2 20	—	—
" 1 in.	0 1 13	—	0 1 25	—	—
	76 3 7	649 14 9	79 1 14	592 13-4	57 1-6

Supposing 648 cwt. of the above kinds of cordage were required:

Value of this at the Bombay rates of 7 7 6 per cwt		Rs. 4839 12 0
Ditto at Bengal rates, viz., at 8 5 9 per cwt., is Rs.	5416 14 0	
Freight to Bombay, say, at one rupee per cwt., ...	648 0 0	
		6064 14 0
Difference in favour of Bombay Coir.....		Rs. 1225 2 0

In calculating the rate per cwt., the Bengal maund is estimated at 82 lb.; and in turning the maunds into English weight, fractional parts

have been omitted. As the authorities at Bombay complained that the market could not always be relied on, for meeting demands as they arose for good Coir cordage for the public service; and as each fresh demand was taken advantage of for raising the price or for trying to pass off inferior articles at a high rate: a rope-walk has been authorised (January 1853) to be established at the Mazagon Dockyard, in order to enable the Indian Navy and Public Department to be supplied with good Coir cordage. The Collector of Mangalore was to supply the Maldive, probably Laccadive Coir, at thirty rupees per candy, and three rupees for boat freight to Bombay. The above account of this use of the Cocoa-nut palm would be very incomplete if we omitted all notice of the various purposes to which Cocoa-nut fibre is applied in Britain and in which so much ingenuity is displayed. The statement frequently made of the Cocoa-nut Palm growing only in the vicinity of the sea, in consequence of the presence of salt in the soil, has not been noticed; nor the common custom of placing some salt round a cocoa-nut, when it is planted and expected to germinate. The sea-coast is well known to be distinguished by its moist climate, as well as by the soil below the surface being moist. Both these afford facilities for the growth of the plant, while the salt which is often placed round the germinating nut is positively useful in preventing white ants from eating it up. In consequence of the injury these cause, it is considered preferable to transplant the young plants when they have put forth three or four leaves, and in rainy weather, *i. e.*, in May and June, keeping the plantation clear from weeds and white ants. We therefore borrow the following contemporary account of the articles exhibited at the Great Exhibition of 1851. "It is instructive to witness the many useful and ornamental purposes to which the vegetable fibre of the Cocoa-nut may be applied. Of the manufacture of the fibre which envelopes the shell of the nut, the principal exhibitors at the Crystal Palace were Messrs. Wildey and Co., of Holland Street, Blackfriars Road, and Mr. Treloar, of 42, Ludgate Hill. The first-named firm showed specimens of Cocoa-nut fibre in various stages of preparation. Commencing with the husk, we have first the cleaned fibres, separated from the intervening vegetable substance; then, a selection and preparation by patented machinery of the fibre for making brushes and brooms—a substitute for bristles; and next we have the fibres still further cleaned, curled, and dyed to resemble horse-hair, such as upholsterers use for stuffing mattresses; and, lastly, follow samples of yarn and cordage of different kinds, together with matting, door-mats, and netting for sheep-folds. "The articles exhibited by Mr. Treloar still further illustrate this novel and interesting manufacture. The stair-carpets and floor-mattings produced by this exhibitor consist of upwards of twenty different registered patterns, all of which are new, and one of which now covers the floors of the Symposium, at Gore House. The brushes comprise every kind; and, so far as it is possible to form an opinion from mere observation, they appear quite as well adapted, for all ordinary purposes as the best bristle brush—while no doubt, the difference in price is considerable. It is not easy, one would suppose, to place much ornament about a door-mat, without interfering with its utility. But Mr. Treloar has succeeded in producing, from a variety of shades of colour, a very ornamental door-mat, having a crown worked in the centre. There are a great number of small articles, such as table-mats, fancy baskets, &c., all made of the same useful material. But the greatest novelties yet produced from Cocoa-nut fibre are the bonnets and hats shown by this exhibitor. These are of a bright Cinnamon colour, and attract considerable notice on account of the ingenuity displayed in their fabrication." The Esoo fibre might well be intermixed with that of the Cocoa-nut for some of the above purposes. To give some idea of the importance of the Cocoa-nut Palm, we may conclude with the following table of the value of the Imports of Coir and Coir rope into the three Presidencies for three years; for which I am indebted to the tables of the Statistical Department of the India House.

Coir and Coir Rope imported into	In year 1847-48.		In Year 1848-49.		In Year 1849-50	
	Foreign	India.	Foreign	India.	Foreign	India.
Calcutta.....Rs...	27,438	85,780	21,615	55,999	21,073	65,261
Madras.....	45,987	15,598	57,323	17,309	44,711	23,900
Bombay.....	873	76,571	333	116,338	1.618	148,210

Subjoined is a tabular view of the Exports and Imports of the different products of the Cocoa nut, for the year 1850-51, in order to show the extensive influence of the plant This must not be estimated simply according to the value of money in Europe but in India, and the tree viewed as the source of employment and of comfort to great numbers of the people of the East. But it is obvious that these Exports and Imports give but a small idea of the usefulness of the plant to the people where it is indigenous, as they find a use for every part of it. In the following table, a few trifling entries appear, and also some imports from places from whence we should not expect them; but this is owing to ships' stores being sometimes landed and sold, instead of being used on board of ship. In some cases the value only is given, but generally both quantity and value, in the official Reports published in India. It is from these that the following facts have been taken:

COIR.

BENGAL PRESIDENCY.

The details of the foregoing tables do not yet give a complete view even of the external commerce of Coco-nut products, for the Imports and Exports *by land* from or into neighbouring districts or from and into Foreign States do not appear. And of those imported, the quantities retained for home consumption are not distinguished from those which are re-exported, and which, though they cannot be enumerated again in the grand total, yet contribute to the activity of commerce. We have, therefore, prepared the following table of the Re-Exports of Cocoa-nut products, from the same official Reports. Some discrepancies appear, as, for instance, no Cocoa-nuts are entered as exported from Malabar, Canara, or Goa; and yet, in the Bombay lists, they are stated to be largely imported from these very districts.

BENGAL PRESIDENCY.

In the Imports into Bombay from the African Coast, there appears an article entitled Cocoa-nut Jarry, of which 449, valued at 386 rupees, were imported; and there were re-exported, 280, valued at 170 rupees, to the Persian and Arabian Gulfs, and 2600, valued at 43 rupees, to Sindh. Here there is evident discrepancy, but the total is made 2880, valued at 213 rupees. In addition to these purely Indian exports and imports, it must be remembered that this Palm is extensively cultivated, and everywhere equally useful. The culture has greatly increased in Ceylon, as well as on the Malabar coast of India. The imports of Oil we here see have greatly increased, and amounted, in the year 1853, to 164,196 cwt.; and will probably continue to increase, as it will be long before there is a limit to the demand. Of Coir, about three millions of pounds used to be manufactured in Ceylon, when the Dutch held that colony. In the year 1838, there were imported into Britain—of Coir rope and twine, 5842 cwt., and of Coir fit for making into mats, 167 tons 13 cwt. Of the imports of Coir, &c., from Malabar and from Ceylon, we may form some idea, from the following note, from the best authority, that of the Messrs. Noble, who state respecting the "imports from Cochin of Coir yarn, rope, junk, and fibre into this country that there exist no certain data in this article on which to form a correct judgment (a great portion being taken into the same ship, both at Cochin and Ceylon, as broken storeage, of which a very uncertain account is kept), a general idea can only be given of quantities, which are as under:

Coir Yarn, - - -	about 1300	tons annually.
„ Rope, - - -	„ 800	„
„ Junk, - - - -	„ 1000	„
„ Fibre, - - -	„ 150	„

"From Ceylon we get rather over 2000 tons of yarn and about 900 tons of rope. Junk is now only a small article from this port. Of fibre we get about 260 tons to 300 tons."—*Royle.*

(2773) COIX, a genus of plants belonging to the natural order of Grasses. And of the species, *C. Lachryma*, has hard strong fruits, which are known by the name of Job's Tears. These fruits are supposed by some writers to be strengthening and diuretic.—*Engl. Cyc. page* 60.

(2774) COIX INDICA. COIX MILLET. A Burmese species of Coix, Job's tears, has large esculent seeds which are parched, like Indian corn in America, and they are often for sale in the Tenasserim bazars.—*Mason.*

(2775) COIX LACHRYMA, is extensively cultivated in the South of China, for weaving floor-matting of various degrees of fineness, the coarser kinds of which are used also for constructing sheds to screen workmen when building houses and even the walls of the huts tenanted by the poor; the best comes from Lientan, west of Canton. No grasses are cultivated in China for food for animals, but the country produces many species fitted for rearing flocks and herds.—*Williams' Middle Kingdom, page* 277. A great deal of *Coix* (Job's tears) is cultivated in the Khasia Hills about Moflong: it is of a dull greenish purple, and though planted in drills, and carefully hoed and weeded, is a very ragged crop. The shell of the cultivated sort is soft, and the kernel is sweet; whereas the wild Coix is so hard that it cannot be broken by the teeth. Each plant branches two or three times from the base, and from seven to nine plants grow in each square yard of soil: the produce is small, not above thirty or forty fold.—*Hooker Him. Jour. Vol.* ii. *page* 289.

(2776) COLCHICACEÆ. MELANTHACEÆ, *R. Brown.* Herbaceous plants. Root fibrous or fasciculate. Rhizoma sometimes a fleshy corm, sometimes creeping horizontally. Stem simple, seldom branched. Flowers complete, or from abortion unisexual, often radical. Perianth free, corol-like, 6-leaved, all distinct, or united at the base into a tube. Stamens 6, inserted into the receptacle, or into the perianth. Anthers opening outwards. Ovary 3-celled. Style 3-parted. Ovules affixed to the inner angle of the cells. Capsule divisible into 3. Seeds with a membranous testa. Embryo straight within a fleshy or cartilaginous albumen. (*R. Brown* chiefly.) The Melanthaceæ are allied to Junceæ and to Liliaceæ, are found in temperate parts of the world, and are remarkable for secreting Veratria.—*Royle.*

(2777) COLCHICUM. The Cormus and Seeds of Colchicum autumnale, *Linn.* Colchicum, or Meadow Flower, is well described by Dioscorides. It was used by the Arabs, and is their *sorinjan*; they give *kuljikoon* as its Greek name. The Hermodactyls (Sweet and Bitter *sorinjan* of the Arabs) of the later Greeks and Arabs were no doubt species of this genus. Dr. Royle's specimens have been described by Dr. Pereira.—*Royle, p.* 601. A tincture of Hermodactyl is prepared by taking Hermodactyl (*soorinjan tulk*) powdered five ounces, proof spirit two pints; and in use and dose is the same as of the colchicum tincture, for which on emergency this may be substituted.—*O'Shaughnessy.*

(2778) COLEOPTERA, (κολεόπτερα) a name first applied by Aristotle ('Hist, Anim.' i. &c.), and now universally adopted, to designate one of the orders into which Insects are divided, the species of which order are commonly known by the name of Beetles. The insects, then, which constitute the order *Celeoptera*, may be characterised as having four wings, of which the two superior are not suited to flight, but form a covering and protection to the two inferior, and are of a hard and horny or parchment-like nature, and when closed, their inner margins, which are straight, touch and form a longitudinal suture (*fig.* 16, *c.*); the inferior wings, when not in use, are folded transversely under the superior, and are membranous. From this character of having the wings in a sheath, the term *Coleoptera* was applied, it being composed of the two Greek words κολεός a sheath, and πτερά, wings. The superior wings, which form the sheath, are generally called elytra.—*Engl. Cyc. page* 62.

(2779) COLEUS BARBATUS, a very aromatic plant of India, of the family Labiatæ.—*O'Sh. page* 491.

(2780) COLE-WORTS. Brassica oleracea. A variety of cabbage, of little value for the plains, might succeed on the hills, requires treatment similar to cabbage.—*Jaffrey.*

(2781) COLLINSIA. *Scrophularineæ.* COLLINSIA GRANDIFLORA.—These plants are mostly all of a bright colour, and well adapted for borders to a flower garden, the colours are mostly yellow; but the *Scabriuscula* is red and yellow, these plants require a tolerable good soil with plenty of water.—*Riddell.* Seeds of this annual often come to Madras, usefulness very doubtful owing to its tender nature; the generally cultivated varieties are natives of California.—*Jaffrey.*

(2782) COLLOMIA COCCINEA. *Polemoniaceæ.*—These plants have a weedy appearance and though cultivated in Europe are hardly worth the trouble.—*Riddell.*

(2783) COLOCASIA, a genus of plants belonging to the natural order *Araceæ.* The species are excessively acrid; the leaves of *C. esculenta* excite a violent salivation and burning sensation in the mouth. Notwithstanding this property many of the species are used as food by the natives of the South of Europe. The leaves and roots of *C. esculenta, C. himalensis, C. antiquorum,* and *C. nucerenata,* under the names of Cocoa-nut, Eddoes, and Yams, when boiled or roasted, are common articles of diet in

hot countries. Whole fields of *C. macrorhiza* are cultivated in the South Sea Islands under the name of Tara or Kopeh roots. In the Himalayas the species which is called *C. himalensis* forms a chief portion of the food of the Hill tribes. Medicinally the root is stimulant, diaphoretic, and expectorant. The whole of the species are remarkable for containing a milky juice. They are cultivated in Portugal, Greece, and Egypt.—*Engl. Cyc. p.* 69. Wight describes Colocasia antiquorum, cuculata, fornicata, Indica, montana, nymphæifolia, odora, and virosa.

(2784) COLOCASIA ANTIQUORUM. This plant of the arum tribe is grown by the natives of Tenasserim for its tubers, that supply the place of potatoes.—*Mason.*

(2785) COLOCYNTH, Citrullus (*Cucumis*, Linn.) Colocynthis. Coloquintida, Bitter Apple, Bitter Cucumber.

Hun-zil, Arab.
Makhal, Beng.
Titta Commodoo, Cyng.
Indrahun ka-phul, Duk.

Colocynthis, L. E. D.
Peponum Pulpa exsiccata, L. D.
Pulp of the fruit, E.
Cucumis, *Linn.* (now Citrullus) Colocynthis.
Colocynth.
Monœcia Monadelphia Linn.

The Colocynth (κολυκμυδις of the Greeks and *Hunzal* of the Arabs) has been used in medicine from the earliest times, and is one of the plants supposed to be the *Pakyoth* or *wild gourd* of Scripture. Annual Herb. Roots thick, whitish. Stems procumbent, angular, hispid. Leaves cordate-ovate, divided into many lobes; lobes obtuse (but rather acute in the Linnæan specimen, and as represented by St. and Ch. iii. t. 138, from a plant grown in Chelsea Garden from seed sent from the Mediterranean, of a bright green on the upper surface, whitish below, and muricated, from being covered with small white hairs and often hair-bearing tubercles. Petioles as long as the lamina. Tendrils short. Flowers axillary, solitary, stalked. Calyx with 5 subulate segments. Female flowers with the tube of the calyx globose, and somewhat hispid, the limb campanulate, with narrow segments. Petals small, yellow, with greenish veins, scarcely adherent to each other and to the calyx. Fruit globose, smooth, about the size of an orange, with a thin but dense rind, 6-celled, pulp very bitter. Seeds ovate, not marginate, whitish, sometimes brownish, bitter. Extending from the south of Europe to Syria and the south of India. Found in various parts of India, as on the sandy lands of Coromandel (*Roxburgh*), Peninsula (*Wight*), Deccan (*Col. Sykes*), sea-shores of Guzerat (*Gibson*), Kaira (*Burns*), near Delhi (*Mackintosh and Rankin*), in Bengal Dispensatory also (*Falconer*). Dr. Royle had heard of it in this direction, but on sending for *Indrayun* and *Bisloombah* plants, which are Arabian and Indian names for the Colocynth, a species of a nearly allied species, with oval instead of globular fruit, was obtained. This he named *C. Pseudo-Colocynthis*, and figured (Himal. Bot. t. 47. fig. 2). A good supply of Colocynth may therefore be obtained for the public service or for commerce, from India, whence it has sometimes been imported; north of Africa, Egypt, and Nubia. It is possible that in some of the localities usually cited, some nearly allied species may be found instead of the true Colocynth. Colocynth occurs in two forms. 1. *Unpeeled*, from Mogadore, in its entire state, and covered by its hard yellow rind. 2. *Peeled*, from the Levant, North of Africa, and South of Spain; with the rind peeled or pared off, and the pulp dried, when the fruit is ripe. It then appears in the shape of white balls, which are light, porous, and spongy, but tough, usually with the seeds forming about ¾ of the whole weight. The smaller variety of fruit is considered the best, and is sometimes imported with the seeds removed. This is always required to be done before any preparations can be made. The seeds are bitter; but a good deal of the bitterness may be removed by repeated washings in water. The pulp is without odour, but is nauseously and permanently bitter. It is with difficulty reduced to powder (*Poudre de Coloquinte*), and may therefore with a magnifier be seen in pills which have been made up with the pulp instead of from the Extract. Both water and Alcohol extract its active properties. Analyzed by Meisner, the pulp was found to contain of Fixed Oil 4·2, Bitter Resin, 13·2, Bitter Principle (*Colocynthin*) 14·4, Extractive 10, Gummy matters 30, Phosphate of Lime and Magnesia, 5·7, Lignin 19·2. The *Colocynthin* is not, however, a pure vegetable principle. Examined by Herberger and Braconnot, it was of a reddish-yellow colour in mass, but yellow when in powder, transparent and friable, excessively bitter, burning like resins, soluble in five parts of cold and in less boiling water; equally soluble both in Alcohol and Ether. Acids and the deliquescent salts precipitate it as a coherent and viscid mass; alkalis do not precipitate it, neither does gall-nut when it is quite pure. It contains Nitrogen, and, according to Braconnot, restores the colour of Litmus reddened by acid. (*Soubeiran.*) *Action. Uses.* Colocynth is a powerful Hydrogogue Cathartic, but an irritant poison in large doses. —*Royle, p.* 494. Dr. Burn states colocynth of two kinds, occur in Guzerat, the Cucumis colocynthis, and the C. pseudocolocynthis.—*Spry's Suggest. p.* 43.

(2786) COLOPHANE. This is a resinous powder procured in a peculiar way by treating Pine Resin with nitric acid. Its febrifuge proper-

ties have been attested by 55 cases from distinguished practitioners, but Military Surgeons at Ajaccio, Rome and Rochefort, think very slightly of its powers, and it is not a substance likely ever to become of any importance in medicine.

(2787) COLOPHONIA, (in French the wood is called Bois de Colophane), a genus of Plants belonging to the natural order *Burseraceæ*. It has an urceolar, bluntly 3-lobed calyx; 5-roundish ovate petals inserted under the disc; imbricated in the bud: 6 stamens one half shorter than the petals; equal in length to the calyx; the disc 6-lobed. It is to this genus that De Candolle refers the tree producing the Bois de Colophane of the island of Mauritius, and calls it *C. Mauritiana*. In his description of the tree he says the fruit is unknown. Lindley, in his 'Flora Medica,' gives *Colophonia Mauritiana*, De Cand. *Bursera paniculata*, Lam., *Amyris Zeylanica*, Retz., and *Balsamodendron Zeylanicum*, DeCand., as synonyms of *Canarium commune*. This last is described as a small tree with 7-11 leaflets on long stalks, Ovate-oblong, acute or shortly acuminated, quite entire, stipules oval; the panicles of flowers terminal, divaricating; the flowers 2-3 together; almost sessile; when young covered over by broad ovate concave silky bracteala, the calyx silky externally, the drupes oblong, black. The bark of this plant yields a limpid oil, with a pungent turpentine smell, which congeals into a buttery camphoraceous substance. It possesses the same properties as Copaiba. Don says:—"When the nuts are mature they contain a sweet kernel, which does not become rancid, and which resembles a sweet chestnut; they are eaten both raw and dressed by the inhabitants of the Moluccas, Banda and New Guinea: and an oil is expressed from them, which is used at the table when fresh, and for lamps when stale; bread is also made from them, cakes, biscuits, &c. for the table. Eaten fresh they are apt to bring on diarrhœas and dysenteries, and to occasion an oppression at the breast." The same tree is also said to yield East Indian Elemi. It is a native of the continent of India and of the islands of the Eastern Archipelago. —*Eng. Cyc. Vol.* II. *page* 70.

(2788) COLOMBO ROOT, CALUMBO ROOT.

Kalamboo khoo, CYNG.	Radice di Columbo. IT.
Columbo wortel, DUT.	Raiz de Calumba, PORT.
Racine de Calumbo, FR.	Raiz de Colombo, SP.
Kolumba wurzel. GER.	Columboo vayr, TAM.
Kalumb-ka jur, GUZ. HIND.	

The Colombo plant (*Cocculus palmatus*), is produced on the Eastern Coast of Africa, and in small quantities in Malabar. As met with in commerce, it is in slices of one or two inches in diameter, one-eighth to half an inch thick, occasionally perforated in the centre, much wrinkled, grayish externally, and a dull yellow within; the taste is exceedingly bitter, smell heavy, powder of a grey colour, and very apt to attract moisture from the air. Colombo-root is very subject to decay by worms, and is therefore generally packed in black-pepper to preserve it. It is brought to Bombay from Mozambique; and is re-exported to England.—*Faulkner*.

(2789) COLOURS, from the mineral kingdom, are procurable in Southern India from the following places:—

Alumina coloured with madder lake (prepared from the munjeeth or Rubia tinctoria),	Chingleput.
Antwerp red,	Ganjam.
Burnt sienna,	Hills near Salem.
Bright yellow ochre,	Hills near Cuddapah.
Brown ochre,	Chingleput.
Cologne brown.	Neilgherry Hills.
Cream colored ochre.	Hills near Salem.
Dark shade of grey ochre,	Nuttum Hills
Dark umbre,	Neilgherry Hills.
Deep yellow ochre (common in the bazars of Madras,	Madras.
Flesh coloured ochre.	near Salem.
Indian red.	Hills near Chingleput.
Iron sand,	Bimlipatam.
Lavender coloured ochre,	Bangalore.
Light red ochre (prepared from the yellow ochre,)	Nuttum Hill.
Orange ochre, (made from the yellow ochre by heat),	near Cuddapah.
Pale yellow ochre,	in Nuttum Hills.
Peroxide of manganese.	Mahratta Country.
Plumbago or black lead,	Vizianagarum and Gol. condah.
Puce coloured ochre,	Bangalore.
Purple ochre,	Hills near Chingleput.
Raw umber,	Neilgherry Hills.
Raw sienna,	near Salem.
Roman ochre,	Chingleput.
Salmon coloured ochre,	Salem.
Silvery white kaolin,	Bimlipatam.
Ultramarine (prepared from the lapis lazuli,	from Bombay.
Venetian red,	in the Bazars in Madras.
Warm stone coloured ochre,	near Chingleput.
White ochre or porcelain earth,	Bangalore.

(2790) COLUBRIDÆ, a family of snakes, the last of the sub-order *Colubrina* of Dr. J. E. Gray. The Colubrina include the families *Hydridæ*, *Boidæ*, and Colubridæ.—*Eng. Cyc. p.* 71.

(2791) COLUBRINA, a genus of plants belonging to the natural order *Rhamnaceæ*. —*Eng. Cyc. p.* 71.

(2792) COLUMBIDÆ, a natural family of Birds, comprising the Pigeons, Doves, and Turtles. The distribution of this family is very extensive, the form occurring almost everywhere, except within the frigid Zones. The species are most abundant in Southern Asia and the Great Indian Archipelago. The following definition includes the *Columbidæ*, to which we shall refer in the present article:—Bill moderate, compressed, covered at the base of the upper mandible with a soft skin, in which the nostrils are pierced, and more or less curved at the point. Feet with three divided toes in front, and one behind.—*Eng. Cyc.*

Vinago (Cuvier.) The species of vinago inhabit intertropical Asia and Africa. They feed on berries and fruits. They are shy and timid, and inhabit the woods. Mr. Selby gives the following, on the authority of Mr. Neill, who, speaking of *Vinago sphenura*, says: "I had two, but both, I believe, were males. Both had a song, very different from the mere cooing

f the ringdove. When they sang in concert hey gave the same little tune, but on different eys. After the death of one, the survivor used o sing at command, or, at all events when inited to it by beginning its tune."

Vinago aromatica.—It is the *Columbia aromaica* of Latham. "The Aromatic Vinago is of a nild and timorous disposition, and is generally een in flocks or societies, except during the peiod of reproduction, when they pair, and reire to the recesses of the forest. The nest is simple, and composed of a few twigs loosely put together, and the eggs are two.

Carpophaga (Selby.) *C. oceanica.* It is the *Columba oceanica* of Lesson. This species, according to Lesson, is the Moulouesse, or Mouleux, of the natives of Ovalan, and though it approaches the Nutmeg Pigeon, *Columba* (*Carpophaga*) *onea*, very nearly, it differs from it in size, being one-third less, and in the distribution of some of its colours. "The Nutmeg Pigeon lives more particularly in the eastern Moluccas, and especially at New Guinea and Waigiou, while the Oceanic Fruit-Pigeon is abundant in the little isle of Oualan, in the midst of the great archipelago of the Carolines, and seems to exist in the Pelew Islands, where Wilson mentions it under the name of cyep." Lesson further observes, that it may be possibly spread over the Philippines, and at Magindanao.

Geophilus nicobaricus. It is the *Columba nicobarica* of Latham, the *C. Gallus* of Wagler. It inhabits the isles of Nicobar, Java, Sumatra, and many of the Moluccas. Authors differ about its habits, some asserting that its nest is placed on the ground, and that the female lays several eggs, the young running as soon as hatched; but Mr. Bennett, who saw them in Mr. Beale's aviary at Macao, says that they were usually seen perched upon the trees, even upon the loftiest branches, and adds, that they build their rude nests and rear their young upon trees similar to all the pigeon tribe.

Lophyrus coronatus. It is the *Columba coronata* of Latham; *Phasianus Cristatus Indicus* of Brisson; *Columbi Hocco*, Le Vaill.; Colombe Galline Goura, Temm.; Great Crowned Pigeon, Edw. A species surpassing in size all the other Columbidæ. Total length from 27 to 28 inches. This bird is found in many of the islands of the great Indian group. Not rare in Java and Banda, abundant in New Guinea and in most of the Moluccas. Nest built in trees; eggs two; cooing of the male hoarse, accompanied by a noise somewhat like that of a turkey-cock when strutting. Its food consists of berries, seed, grain, &c. Flavour of the flesh said to be excellent. "In this magnificent and beautiful bird," says Mr. Selby, "we observe a combination of form different from that of the ground-pigeons; for, instead of the marked affinity to the typical rasorial families, the *Pavonidæ* and *Tetraonidæ*, so decidedly exhibited by these species, both in their mode of life and in their deviation from the usual Columbine figure, we have in the present instance, an approximation of structure much nearer that of some of the *Cracidæ*, another tribe of birds which constitutes an aberrant family of the Rasorial Order; and it is on this account we think that this bird cannot well be placed in the same division with the ground-doves but must constitute the type of a separate group."—*Eng. Cyc. pages* 72, 75, 78, 90 *and* 91.

(2793) COLUTEA, a Papilionaceous genus of Exogenous Plants, consisting of hardy shrubs with pinnated leaves and inflated membranous pods, which explode when suddenly compressed, and which look like vegetable bladders, whence the common English name of Bladder-Senna. The species have yellow or yellow and red flowers of some beauty; and are all found in the south of Europe, in Palestine, and in the Himalaya mountains.—*Eng. Cyc. page* 93.

(2794) COLYMBIDÆ, a family of Swimming Birds (*Natatores*,) having a smooth, straight, compressed, and pointed bill. The species of Podiceps are called Grebes. They haunt the sea as well as the rivers, are excellent swimmers, and dive frequently, as all who have watched the Dabchick or little Grebe (*Podiceps* minor), and have been amused by its quickly repeated plungings, well know. They feed on small fishes, frogs, crustaceans, and insects, and their nests, formed of a large quantity of grass &c. are generally placed among reeds and carices, and rise and fall with the water. *Podiceps* occipitalis (Lesson) may be taken as an example. This Grebe, according to M. Lesson, is remarkable for the delicate tints of its plumage, which is slate-gray (gris ardoise) above and of a satiny white below.—*Engl. Cyc. p.* 95.

(2795) COMBRETACEÆ, an order of Polypetalous Exogenous Plants, with 1-celled inferior fruit, the seeds of which are solitary or nearly so, and pendulous, the stamens definite in number, and the cotyledons convolute. It cannot be doubted that this order has a near relation to *Myrtaceæ* and especially to *Punica*. Dr. Lindley considers it to be in closer alliance with *Lauraceæ* and *Compositæ*. The species known as Myrobalans are tropical shrubs or trees, with alternate or opposite leaves destitute of stipules, and long slender stamens. The order does not contain any plants of much importance for their useful properties. Some of them are astringent and used for tanning, and the kernels of others are eatable; they are chiefly valued for their brightly coloured showy flowers, especially in the genus Combretum —*Eng. Cyc. page* 100.

(2796) COMBRETUM WIGHTIANA. A fragrant flowered species of Combretum is com-

mon on the hills near Maulmein—it is a straggling shrub, with winged fruit.—*Mason.*

(2797) COMBS.

Peignes, Fr.	Peltini, It.
Kamme, Ger.	Pentes, Port.
Kunghae, Guz. Hind.	Peines, Sp.

Combs are well-known implements formed of horn, bone, tortoise-shell, wood, &c. for cleaning and adjusting the hair.—*Faulkner.* In Ceylon the marginal pieces of tortoise shell are used at Point de Galle in the manufacture of bracelets and necklaces formed of a chain of shell, it resembles amber in appearance: these bear a higher price than such as formed by the darker shell. In Ceylon there is a great demand for tortoise-shell for the manufacture of Combs which are worn by males as well as females among the Cingalese. In the numerous excesses into which English costume has been carried the size of the back Comb worn by ladies has never attained that of the Cingalese men, who also wear a narrow long bent Comb across the forepart of the head—the lighter colored shell is most esteemed by them. Five pounds is a moderate price for a tortoise shell back comb, which increases in value according to the size and quality of the shell: hair pins of tortoise-shell are worn by the women: gold and silver being substituted for full dress: these hair pins are among the articles purchased by passengers in the steamboats.—*Rhode M.S.S.*

(2798) COMEPHORUS, a genus of Fishes belonging to the family of Gobies. There is only one species, which is found in the fresh-water lake of Baikal. It is not taken by the fishermen, but is found dead on the shores after the severe storms to which that lake is frequently exposed. The fish is about a foot in length, and of a soft greasy texture. It is collected and pressed for oil, but is not eaten.—*Engl. Cyc. p.* 100.

(2799) COMMELYNA. Commelyneæ. Some of the plants of this genus are very handsome, the colour of the flowers mostly blue, and propagated by dividing the tubers.—*Riddell.* Wight describes Commelyna Bengalensis; cristata; nana; papilionacea; polyspatha; and scapiflora.

(2800) COMMELYNA COMMUNIS, Lin.—Calf-Grass.

Kunnoo koottie pilloo, Tam.	Neeroo kussuvoo, Tel.
	Vatsa priam, Sans.

The succulent leaves of this plant, which is improperly called a grass, are used by the Hindoos of the southern provinces for feeding young calves, when they wish to wean them from their milk. The plant has a small delicate blue flower and is found growing on the banks of water courses; along which it spreads rapidly sending suckers into the ground.—*Ainslie's Mat. Med. page* 301. Mr. Jaffrey describes the Commelyna communis under the Tamul name of Kannangkeeray, as a weed with pretty blue flowers, commonly found in lawns; the leaves are used by the natives mixed with other greens.

(2801) COMMELYNA NUDIFLORA, is a species of cucumber which Dr. Honigberger received from the Himalayas under the name of Kandoolee.

(2802) COMMIA, a genus of plants belonging to the natural order *Euphorbiaceæ. C. Cochin-chinensis* is a small tree with a resinous juice. It has alternate entire smooth leaves. The male flowers are amentaceous, the catkins consisting of imbricated 1-flowered scales, axillary and short; the female flowers racemose terminal, and small. This tree yields a gum which possesses emetic and purgative properties. It is recommended in cases of dropsy, but has not been introduced into European practice. It is a native of Cochin China.

(2803) COMMIPHORA MADAGASCARENSIS. (*Lindl. Fl. Med.* 173.) *Syn.* Amyris Commiphora, (*Roxb. Fl. Ind.* ii 244.) Balsamodendron? Commiphora, (*Wight and Arnott, Prod.* i. p. 96.) This is a native of Sylhet, Assam, and Madagascar; it blossoms in the Botanic Garden of Calcutta about February and March, but seldom ripens its seed. It has been briefly noticed under its synonim. A resinous substance named Googul, (*Hind.*) Moogl (*Arab*) is met with in all the bazars of India. It much resembles myrrh, and is said by some good authorities to constitute the bulk of the article exported from Bengal as East Indian myrrh. Royle considers the *Googul* identical with the Bdellium of commerce and he ingeniously traces in *Budleyoon* and *Madelkon* (the Greek synonymes of Googul), the Βδελλιον and μαδελχον of Dioscorides. A tree in the Seharunpore Garden, pointed out as the Googul tree, had scaly bark exactly conformable to Roxburgh's description of his Amyris. *Bdellium*, Dr. Ainslie, vol. i. p. 29, gives an excellent summary of all the information extant when his work was published, regarding this interesting substance. He adduces as synonymes, Bdellium. Kookool, *Tam.*, Googooloo. *Tel.*, Googula. *Cin.*, Aflatoon, *Arab.*, Mukul, *Pers.*, Googul, *Hind.*, known as Bdellium. He describes the gum resin as semi-pellucid, yellowish, or brown, inodorous and brittle, softening between the fingers, in appearance not unlike myrrh, of bitterish taste, and rather strong smell. He states however that it is all brought from Arabia and Persia, where the tree is called *Durukht-i-mukul.* In the bazars of India it is said that the googul "comes from the Hills." (Royle. p. 177.) The medicinal properties of Bdellium are exactly like those of myrrh, and being much cheaper, it may be preferred for Dispensary practice.—*O'Shaughnessy, p.* 287.

(2804) COMOCLADIA DENTATA, of Cuba, is remarkable for a milky corrosive juice which

turns to a fixed black colour.—*O'Shaughnessy, page* 281.

(2805) COMPASS.

Soekompass, DAN.	Bussola. IT.
Zeekompass. DUT.	Composso de marear, PORT.
Compas de mer, Boussole, FR.	Kompass korabelnui RUS.
Kompass. GER.	Sjocompass, Aguja de marear, SP.

A well-known instrument, composed of a magnetized needle and card, employed in directing the course of vessels at sea.—*Faulkner.* The compass, for nautical purposes, is, at present, used by the principal native traders of Southern and Eastern Asia and of the Archipelago. The Bugis of Celebes, for example, use small rude compasses, made expressly for them by the Chinese of Batavia, at the very moderate cost of from one shilling to eighteen-pence a-piece. The directive power of the magnet is said to have been known to the Chinese for many ages,—by their own account, no less than 2634 years before the birth of Christ.—*Crawfurd Dict. page* 115.

(2806) COMPOSITÆ, the largest known natural order of Plants. It consists of Monopetalous Exogens with syngenesious stamens, and an erect solitary ovule in a simple 1-celled inferior ovary, the style of which is divided into two arms; the flowers are always arranged in dense heads, or capitula, and are surrounded by one or more external rows of bracts forming an involucre.—*Engl. Cyc. page* 102.

(2807) CONCH OR CHANK SHELLS. These and their uses have already been noticed under the heads, *Bracelets and Chanks*, to which reference can be made. The manufacture of rings for the arms and ancles, from conch-shells imported from the Malayan Archipelago, is still almost confined to Dacca: the shells are sawn across for this purpose by semicircular saws, the hands and toes of the workman being both actively employed in the operation. The introduction of circular saws has been attempted by some European gentlemen, but steadily resisted by the natives, despite their obvious advantages. —*Hooker Vol.* II. *page* 254.

(2808) CONCHA FLUVIATILIS. Sea-shell is used by the Hakims as a medicine, and with the common people, this river fresh water shell serves for a spoon, out of which they take their medicine.—*Honigberger, p.* 260.

(2809) CONCHOLOGY is that branch of science which teaches the structure and forms of the shells which are the hard external covering of the animals belonging to the class *Mollusca.* Although these shells present great variety of forms, and are variously marked, they are only a subsidiary part of the structure of the animals to which they belong. Hence amongst naturalists the shells are only studied in connection with the structure of the animals which inhabit them. I would have wished to have given an account of these animals with their shells, in articles Mollusca, Brachiopoda, Tunicata, Conchifera, Gasteropoda, Pteropoda, Cephalopoda; also under the heads of the more important of the families and genera of the *Mollusca*, but my arrangements to obtain the same have failed.—*Eng. Cyc. p.* 117.—*Editor.*

(2810) CONDAMINEA, a genus of plants belonging to the natural order *Cinchonaceæ.*—*Engl. Cyc. page* 117.

(2811) CONNESSI BARK, TELLICHERRY BARK.

Conessie, FR.	Corte-de-pala, PORT.
Curayia, Curaija, GUZ. HIND.	Cheeree, Kutaja, SANS.
	Veppalei, TAM.
Palapatta, MALEAL.	Pala codija, Manoopala, TEL.
Codaga pala, MAL.	

Conessi bark is the produce of a plant belonging to the natural order *Apocynaceæ*, a native of the western coast of Hindustan. It is the *Wrightia* (Nerium) *antidysenterica*, and is a valuable astringent.—*Engl. Cyc. page* 122. Mr. Faulkner describes it as a native of Ceylon, Mauritius, the Malabar Coast, and many other parts of India. It is astringent and bitter, and is considered febrifuge; it has also been given with alleged advantage in chronic dysentery. The seeds of the plant are termed *Indrajow.* —*Faulkner.*

(2812) CONESSI SEED.

Lisan ul assafeer. ARAB.	Indrayava, SANS.
Indrajow, GUZ. HIND.	Veppalei arisee, TAM.
Ahir, PERS.	

The seed of Wrightia antidysenterica (*Nerium antidysentericum*), are covered with a kind of downy tuft, somewhat resembling the down of the thistle. Two kinds are distinguished, the *sweet* and *bitter.* The former has a pleasant taste not unlike that of oats, which they also resemble somewhat in appearance; but are longer and more slender. An infusion of the roasted seed is given as a safe and gentle restrainer in bowel complaints; the decoction is employed in fever cases. The latter are intensely bitter, and used as a vermifuge.—*Faulkner.*

(2813) CONFECTION OF BLACK PEPPER. In compounding this drug in India, for elecampane root (inula helenium), Dr. O'Shaughnessy recommends the substitution of the goonch root, Abrus precatorius. The Edinburgh Pharmacopeia uses liquorice root and for the fennel seeds of the London preparation, the seeds of Panmuhori, or Sonf, (Fæniculum panmorium) are an adequate substitute.—*Beng. Phar. p.* 273.

(2814) CONFERVÆ abound in the warm water from the hot springs of Soorujkhund, in Behar, and two species, one ochreous brown, and the other green, occur on the margin of the tanks themselves, and in the hottest water; the brown is capable of bearing the greatest heat and forms a belt in deeper water than the green:

both appear in broad luxuriant strata, wherever the temperature is cooled down to 168° and as low as 90°.—*Hooker Him. Jour. Vol.* 1. *p.* 28.

(2815) CONIUM MACULATUM, *Linn.* Conii Folia, L. E. D. Conii Fructus. L. Leaves and Fruit of Hemlock. There is little doubt of this being the κωνειον of the Greeks, and the *cicuta* of the Romans, as has been long supposed and as has been well argued by Dr. Pereira. This must not, from the similarity of name, be confounded with *Cicuta maculata*. *Cicuta virosa* occurs in Cashmere, where it is called *Zehr-googul*, or poison turnip. Persian, *Salep-e-Shaitan* or Devil's Salep. The objection that it is not so clearly described as to be readily distinguished from other Umbelliferæ, would apply to accounts of many officinal plants, even in comparatively modern works. It is the *shokran* of the Arabs, who give *chunun* as the Greek name.—*Royle.* Conium Maculatum. (Spotted Hemlock.) Κωνειον, Dios. is found in Europe, east of Asia and America. This plant is of great importance as a medicine, and derives additional celebrity from being considered to have been used as the Athenian state poison, by which Socrates and Phocion perished. In the form of fruit, in locality (Crete and Candia), in the effects as a poison, and in some properties as a remedy, this article corresponds exactly with the descriptions of Dioscorides and Nicander—one very strong fact is, that no other poisonous Umbelliferous plant is found in Greece but this, which grows plentifully in the localities from which historians state the Athenian poison was gathered. For medical uses the extract of hemlock is chiefly employed as an anodyne in scrofulous or cancerous affections. In rheumatism, neuralgia, and painful ulcerations, especially those of a syphilitic character, hemlock is employed with decided benefit. *Hemlock poultices*, prepared in various ways, are often applied with great advantage to irritable sores, particularly those of a cancerous, or scrofulous, or syphilitic character; 2 ounces of the extract with a pint of water thickened by linseed meal constitute the London form. The bruised leaves themselves are occasionally employed: an ointment is made according to the Dublin Pharmacopœia, by boiling the fresh leaves in prepared lard, and is much used in the cases above mentioned, and also as an application to painful piles.—*O'Shaughnessy, pages* 371.

(2816) CONGANI, a Hood or Pent House, made of reeds, in the Western parts of Tinnevelly, to protect the person from rain.

(2817) CONGEA, In the neighborhood of Maulmain and Amherst, but rarely in the southern provinces, the forest scenery is often ornamented with the numerous large purple bracts surrounding the small inconspicuous flowers of a species of congea. In the distance it bears a strong resemblance to the dogwood tree of the Ohio valley when in flower. There are three different species in the Tenasserim Provinces, Congea azurea, C. tomentosa, C. velutina, but they are all called by the same native names.—*Mason.*

(2818) CONGEA VILLOSA, has leaves of heavy smell, and is used by the natives in medicine.—*O'Shaughnessy, page* 486. Wight gives Congea azurea, 1479; velutina, 1479 & 1566; *villosa*, 1479; and tomentosa, 1479 or 1565.

(2819) CONIFERÆ, a natural order of Gymnospermous Exogens (called by Dr. Lindley *Pinaceæ*), consisting of resinous, mostly ever-green, hard-leaved trees or shrubs, inhabiting all those parts of the world in which arborescent plants can exist.—*Eng. Cyc. p.* 123. In Sikkim and Bhootan, there are twelve Coniferæ, viz. Juniper, 3; Yew; Abies Webbiana, Brunnoniana, and Smithiana; Larch; Pinus excelsa and longifolia, and Podocarpus neriifolia. Of these, four, viz. Larch, Cupressus funebris, Podocarpus neriifolia and Abies Brunoniana, are not common to the North-west Himalaya, west of Nepal, and the other eight are common. Of the 13 natives of the North-west Provinces again, only the following five, Juniperus communis; the Deodar Pinus Gerardina, Pinus excelsa and Cupressus torulosa are not found in Sikkim.—*Hooker Vol.* 1. *p.* 256.

(2820) CONNARUS NITIDA, a shrub about ten feet high, is very plentiful, especially in the Rangoon district, and affords an oil seed of small size, but rich in a sweet oil.—*McClelland.*

(2821) CONNARUS SPECIOSA.

Gwai-douk, Burm.

A large tree, very plentiful throughout the Rangoon, Pegue and Tounghoo districts, where it is known under the name of *Kadon-kadet.* Plentiful in all the forests growing scattered with Teak in the Tounghoo district and in the forests of Pegu. It is a large, heavy and strong timber. Wood, white-colored, adapted to every purpose of house building, remarkable for the quantity of its seed, which are of large size, abounding in sweet oil.—*McClelland.*

(2822) CONOCARPUS ACUMINATA.

Pauchinon, Tel.

This species is a large timber tree, a native of the same places, it flowers during the cold season. These trees are valuable on account of their wood, particularly the first seriman, its timber is universally esteemed for almost every economical purpose. Towards the centre, it is of a chocolate colour and is there exceedingly durable. For house and ship building the natives reckon it superior to every other sort; Pentaptera tomentosa, and teak excepted. The wood of Pauchinon is exceedingly like, and fully

as strong, and as durable, if kept dry as the *C. latifolia*, but exposed to the water, it soon decays; of course it is unfit for the marine yard, but equally fit for house building when it can be obtained straight, which is seldom the case. Rose-wood, Yerroogudda cheva karra, *Tel.* the tulip tree Poorsha, *Tam.* or Gungarani, *Tel.*, are tough woods and well adapted for fine furniture, the latter is generally hollow and can only be obtained fit for chairs &c. It is not, I believe, found in the jungles but abounds in old gardens and about European stations near the sea.—*Rhode M.S.S.*

(2823) CONOCARPUS LATIFOLIA, SERIMAN, *Tel. Combretaceæ*, Icon. 294.

Vellay naga marum, Tam.

This is one of the largest timber trees that are found amongst that chain of mountains, on the Peninsula of India, which separates the Circars from the Mahratta Dominions, where it is a native. It flowers during the cold season, in January and February. Its trunk is erect, straight, varying in length and thickness, the largest or thirty-five, being five feet to the branches, and about six feet in circumference.—*Roxb.* Dr. Wight, writing from Coimbatore, says it is a tall handsome tree furnishing an excellent and very strong timber. The specimens tried there, though not the best, sustained 500lbs. Roxburgh speaks of it in very high terms. Mr. Rohde cannot find that its timber of any size or value is found in Rajahmundry or Masulipatam Circar, these being the only localities in which he has met with it in common use. He thinks this wood is over estimated. He has seen many instances in which it has, though sound when put out, given way in buildings, and he has never seen it above a foot in diameter —*Rohde M.S.S.* On another occasion Mr. Rohde says, if this be the wood known by the name of *Seriman* given by Roxburgh, I must say I never met with any worthy of the character he gives it—it is the common timber of Masulipatam, where I never saw a log of a size exceeding 12 inches diameter. The Tamil name given by Dr. Wight is that of the white Eugenia.—*Rohde.* Other notes in my possession describe this as a large tree, in some cases, but the stem is often so deeply furrowed as to prevent it yielding a good plank. It is found about the sources of the Concan rivers; Kennery jungles; and on the inland Deckan Hills; where it has a stunted and gnarled form; there is a fine specimen of this tree in the neighbourhood of Sydapet, near Madras.

(2824) CONOCARPUS ROBUSTA.

Baibyah, Burm.

This is a very large and strong timber tree, growing plentifully in the Pegu, Tounghoo and Prome Forests along with Teak. Wood, white colored, adapted for fancy work and cabinet making.—*McClelland.*

(2825) CONOPS, a genus of insects belonging to the order *Diptera* and the family *Conopidæ*. —*Engl. Cyc. page* 127.

(2826) CONSERVE OF ROSES.

Gulcund, Guz. Hind.

Consists of rose-petals and sugar mixed in certain proportions, and bruised in a mortar. The conserve of roses met with in the bazars of Bombay, is chiefly obtained from Surat.—*Faulkner.*

(2827) CONUS, a genus of Gasteropodous *Mollusca*, founded by Linnæus. The species are found in southern and tropical seas; and are very numerous. Lamarck records 181 recent; and several of these include varieties.—*Engl. Cyc. page* 128.

(2828) CONVOLVULACEÆ, a natural order of Monopetalous Exogenous plants, with bell-shaped flowers, opening or contracting beneath the influence of light, a plaited æstivation of the corolla 5 stamens, and a fruit with 2 or 3 cells, in which 1 or 2 ovules stand erect. The embryo is crumpled up in the midst of very firm albumen. The common Bind-weeds of the British hedges, the *Ipomœa* and *Convolvuli* of the gardens, offer illustrations of the ordinary state of this order, the species of which have purgative roots; and in the case of scammony, yielded by *Convolvulus Scammonia*, and of jalap, produced by various species of Ipomeæ, are of great medicinal importance. Occasionally the purgative principle is so much diffused among the fæcula of the root as to be almost inappreciable, as is the case in the *Convolvulus* Batatas, or sweet Potato of America, which was the forerunner of the common potato, and gave it its name, and which is still cultivated in the south of Spain and France. —*Engl. Cyc. page* 129. Wight, in Icones, gives Convolvulus bicolor, 835; calycinus, 833; capitulatus, 1366; glomeratus, 1366; hirtus, 834; microphyllus, 1367; pentaphyllus, 834; rhynospermus, 1368; and rufescens, 1365;

(2829) CONVOLVULUS ARVENSIS has angular striated stems; leaves sagittate, somewhat auricled; peduncles usually flowered; sepals ovate, roundish; corolla white or rose colour. It is native throughout Europe in sandy fields and by road-sides; also in China, Persia, and some parts of India. It is very common in Great Britain. This species is said to possess a purgative quality, as also *C. Soldanella*, *C. maritimus*, and *C. macrocarpus.—Eng. Cyc. page* 140.

(2830) CONVOLVULUS ARGENTACEUS. Silver-leaved Convolvulus. (*Hind.* Sumundersokh) Cultivated as a flower: the leaves and juice of the plant are acrid, and applied by the natives to stimulate sores. The seed is used along with salep misri as an aphrodisiac: the half roasted leaves applied to the skin are escharotic: one tola of the seeds is a dose.—*Gen. Med. Top. p.* 181.

(2831) CONVOLVULUS BATATAS. SWEET POTATOES.

Sukkaray vullie kalung, TAM | Uby Castela MALAY.
Pendaloo, DUK. | Kappa kelenga, MAL.
Sukkara Velligudda, TEL. | Sharkara kunda, SANS.
Shukurkund, PERS.

The batatas, or camote of the Spanish colonies (*Convolvulus batatas*, Linn ; *Batatas edulis*, of Choisy, and the *Ipomœa Batatas* of other botanists), belongs to a family of plants which has been split into several genera. It is a native of the East Indies, and of intertropical America, and was the " potato" of the old English writers in the early part of the fourteenth century. It was doubtless introduced into Carolina, Georgia, and Virginia, soon after their settlement by the Europeans, being mentioned as one of the cultivated products of those colonies as early as the year 1648. It grows in excessive abundance throughout the Southern States of America, and as far north as New Jersey, and the southern part of Michigan. The varieties cultivated there are the purple, the red, the yellow, and the white, the former of which is confined to the South. The amount of sweet potatoes exported from South Carolina in 1747-48, was 700 bushels ; that of the common potato exported from the United States, in 1820-21, 90,889,000 bushels ; in 1830-31, 112,875,000 bushels ; in 1840-41, 136,095,000 bushels ; in 1850-51, 106,342,000 bushels. The sweet potato is cultivated generally in all the intertropical regions, for the sake of its roots, and as a legume in temperate countries. In the Southern States of North America, the culture ceases in Carolina under latitude 36 degs. ; in Portugal and Spain it reaches to latitude 40 and 42 deg. ; and as a legume its cultivation is attempted to the vicinity of Paris. In India it is a very common crop ; its tubers are very similar to the potato, but have a sweeter taste, whence the common name ; but it must not be confounded with the topinambur (*Helianthus tuberosus*), a native of Brazil, which is less cultivated. The root contains much saccharine and amylaceous matter. Several marked varieties of the sweet potato are raised in the Polynesian groups. In some islands it forms the principal object of cultivation. It is grown in the Northern districts of New Zealand, at Zanzibar, Monomoisy, Bombay, and other parts of the East Indies. They are raised on the bare surface of the rock in some parts of the Hawaiian islands, and a sourish liquor is procured from them. It was early cultivated on the Western Coast of Africa, for the Portuguese Pilot (who set out on his voyages to the colony at St. Thomas, in the Gulf of Guinea) speaks of this plant, and states, that it is called " batata by the aboriginals of St. Domingo. They are abundant at Mocha and Muscat. Sweet potatoes form a principal and important crop in the Bermudas. The sweet potato of Java, says Mr. Crawfurd, is the finest I ever met with. Some are frequently of several pounds weight, and now and then have been found of the enormous weight of 50 lbs. The sweetness is not disagreeable to the palate, though considerable, and they contain a large portion of farinaceous matter, being as mealy as the best of our own potatoes. In Java it is cultivated in ordinary upland arable or in the dry season as a green crop in succession to rice. A tuberous root (Ocymum tuberosum) an inhabitant of the hot plains is frequently cultivated in Java. It is small, round, and much resembling in appearance the American potato, but has no great flavor. Its local name is kantamy.—*Simmonds' Com. Product, p.* 367.

(2842) CONVOLVULUS BI-COLOR. Two-coloured convolvulus.

Zurd-kulmi, HIND.

A yellow and buff flowered Convolvulus cultivated in gardens.—*Gen. Med. Top. p.* 181.

(2833) CONVOLVULUS DIANÆ (?) Moonlight convolvulus. Chand, HIND.

Cultivated in gardens ; the large fragrant white flowers open in the evening and fade in the morning.—*Gen. Med. Top. p.* 181.

(2834) CONVOLVULUS GANGETICUS : Pink flowered Convolvulus. Cultivated as a flower, and also abundantly wild with several varieties of different colours.—*Gen. Med. Top. p.* 180.

(2835) CONVOLVULUS GEMELLUS. Lin.

Sirroo talie elley, TAM. | Tsinnatalicakoo, TEL.

These leaves are said to have a pleasant smell and mucilaginous taste. When dried, powdered and boiled with a certain portion of ghee, they are considered as a valuable external application in Apthous affections.—*Ains. Mat. Med. p.* 115.

(2836) CONVOLVULUS GRANDIFLORUS. (Ainslie, vol. ii. 219.)

Nagha mooghatei kai, T. | Puthmapoo todmie, SANS.
Munda Valli, RHEEDE. | Alanga, CYNG.

Moonflower. Common on the Coromandel Coast. Capsule or pericarp containing four seeds the size of kidney beans, when dried used in snake-bites ; dose three daily in powder.—*O'Sh. page* 506.

(2837) CONVOLVULUS MALABARICUS.

Paymoostee, TAM. | Kattu kelungu, RHEEDE.

A native of the Malabar coast and of Cochin China, considered by the farriers in India a good horse medicine. Roxburgh in his *Flora Indica*, pp. 466 to 487, describes 34 species of Convolvulus.—*O'Shaughnessy, page* 506.

(2838) CONVOLVULUS REPTANS, Mandavalli, *Rheede*.

Kulmi shak, BENG. | Tootu kura, TEL.

This plant is the Mandavallie of *Rheede* and the Olus vagum of *Rumph*, a native of standing sweet waters, very common in India, affords a

milky juice which when dried is nearly equal to scammony in purgative efficacy. (*Ainslie*, on the authority of Plumier and the Hortus Malabaricus.) The tops and leaves are eaten in stews by the natives.—*O'Shaughnessy, page* 506.

(2839) CONVOLVULUS PÆS COPRA, Roxb. Rabbit weed.

Chagul khooru, BENG. | Schinanna Adamboe ,RHEEDE.
Dapetiluta, HIND. | Bala banda, TEL.

This is a native of the sandy shores of India, where it grows naturally helping to bind loose sand and render it sufficiently stable to bear grass: goats, horses and rabbits eat it. Roxb. —*Rhode M.S.S.*

(2840) CONVOLVULUS REPENS. Lin.

Wullie keeray, or Vullie keeray, TAM.

Ainslie's Mat. Med. p. 258.

(2841) CONVOLVULUS SCAMMONIA. A native of Syria and the Levant, recently discovered by Dr. Burn in Kaira in Guzerat. The proper juice when dried is called *Scammony*. The Scammony of Aleppo occurs in fragments, voluminous, dry, light, spongy, friable, pulverulent, with dull fracture of blackish grey, but covered with grey powder resulting from the reciprocal friction of the pieces, slightly transparent in small flakes, which become white and rather adherent when rubbed with a wet finger, odour disagreeable, taste weak, acrid, bitter, and repulsive, powder greyish white. The species of scammony is often adulterated with concrete juices of a similar kind, with flour, chalk, sand, and earth. According to the analysis of Bourtron La Grange and Vogel, good scammony consists of resin 60, gum 3, extract 2, and earthly and vegetable impurities 25 per 100. The most abundant harvest of scammony is in Smyrna and Aleppo. There are several modes of collection, which gives rise to corresponding commercial varieties. The neck of the root being laid bare is divided transversely, and shells placed around the edges to receive the juice as it exudes. This subsequently thickens in the air. The drug collected in this mode, is called shell scammony. This occurs in small porous masses, sometimes smooth, of reddish or whitish grey colour; of wax fracture, yellowish and half transparent, in thin layers, of disagreeable taste and smell; on drying it becomes adhesive. Instead of shells the leaves of the chesnut tree are sometimes used, and a flattened scammony of good quality collected. If the roots be cut in successive layers, the scammony is inferior, but still esteemed. It is dried either over a slow fire or before the sun, and then moulded into stamped pastiles, of whitish colour. This variety is very rare in commerce. Lastly, an extract is prepared from the expressed juice of the roots and stalks, this is moulded into round masses, of black, vitreous, and resinous fracture. The Arab name of this drug, Ul Sugmoonia, signifies the *purgative*. Several old preparations called "diagredium" (διακρηδιον) are mixtures of scammony with sulphur and liquorice, and are now no longer used.—*O'Shaughnessy, page* 500, 501.

(2842) CONVOLVULUS TURPETHUM ROOT. *Indian Jalap.*

(2843) CONYZA ALOPECUROIDES, Martinique, diuretic. *Syn.* Pterocaulon alopecuroideum, D. C.—*O'Shaughnessy, p.* 419.

(2844) CONYZA ANTHELMINTICA, India. *Syn.* Vernonia anthelmintica, D. C. Bukchie, *Hind.* All parts of this plant are bitter. The powdered seeds are used as a warm medicine. —*O'Shaughnessy, p.* 419. Dr. Honigberger at p. 261, states that Conyza Anthelminthica, Vernonia anthelmintica; Serratula anthelmintica—is officinal at Lahore. It is said, that when the flea-bane is roasted, flies take to flight (see *Bane, Amygdala* and *Juglans regia*) and when the powder of the flea-bane is sprinkled on the floor, fleas disappear.

(2845) CONYZA BALSAMIFERA, India. Soomboong of the Javanese. *Syn.* Blumea balsamifera, D. C. A substitute for sage.—*O'Sh. page* 419.

(2846) COOKIA, a genus of plants belonging to the natural order *Aurantiaceæ*. The species are small trees with impari-pinnate leaves. One species, *C. punctata*, is a native of China and the Moluccas; it has ovate lanceolate leaflets, acuminated, hardly unequal at the base. It is a middle-sized tree bearing eatable fruit about the size of a pigeon's egg, yellow on the outside, the pulp white, rather acrid, but sweet. This fruit is esteemed as an article of diet in China and the Indian Archipelago, and is known by the name of Wampee. There are two or three other species, natives of the East, all known as Wampee Trees. —*Engl. Cyc. Vol.* ii, *p.* 131. In India, Cookia Punctata, the Wampee tree, bears its rough skinned fruit in April and May: it grows in clusters, containing a sweetish acid juice, resembling black currant in flavour. It grows to a large tree, and has very dark green shining leaves. Is rather ornamental, and requires very little care. —*Riddell.* In China, the hwangpi, or whampee, *i. e.* yellow skin, is common and is deemed a superior fruit.

(2848) COOROOKOO OR BRUMADUNDOO OIL. ARGEMONE MEXICANA.

Brumadundoo yennai, TAM.	Oil of Prickly Poppy, or
Brumadundie Noona, TEL.	Jamaica yellow thistle,
Faringie datura ka tel, HIND.	ENG.

This pale yellow, limped oil, may be obtained in large quantities from the round corrugated seeds of the prickly poppy, which was originally introduced from Mexico in ballast, but now flourishes luxuriantly in all parts of India. It was noticed under the head of Argemone mexicana. It is sometimes expressed by the natives and used in lamps, but is doubtless adapted to other and more important uses. In North Arcot it costs from Rs. 1-14-0 to Rs. 2-1-0 per maund. —*Madras Exhibition of* 1855. See ARGEMONE MEXICANA.

(2849) COOPPAY KEERAY, *Tam.* This is the Amarantus polystachyus. Lin.—*Ainslie, p.* 253.

(2851) COPAIVA, COPAIBA.

Baume de Copahu, FR.	Capayva, SP.
Kopaiva balsam, GER.	Faulkner.

Copaiba is the fluid resinous exudation of several species of Copaifera, of C. Langsdorffii. *Dec.* of C. officinalis. Capaiba was first described by Marcgraaf and Piso in 1643 ; but the species is uncertain, as the latter gives no figure, and the former only one of the fruit (supposed by some to be of *Copaifera bijuga*, Willd). Jacquin, in 1763, described a species of Copaifera from Martinique, which he named *C. officinalis*, and which probably yields the little Copaiba obtained from the West Indies. It has, however, been ascertained that several species yield the Copaiba of commerce. The Wood-Oil of some species of *Dipterocarpus* yields a substance closely resembling Copaiba.—*Royle, page* 364.

(2852) COPAL. Chundroos, GUZ. HIND.

A peculiar kind of gum-resin, obtained from a large tree (*Rhus Copallinum*), found in various tropical countries. It is usually met with in irregular, hard, shining, transparent masses; brittle, tasteless, indorous, and generally of a lemon hue, though the best is nearly colourless, bearing a great resemblance to Animi and Amber. It is fusible and inflammable, insoluble in water, and very sparingly so in alcohol. It is, however, dissolved by ether and some other essential oils, though with difficulty. The gum-resin is employed with oil of turpentine in making "Copal Varnish." Copal is largely imported into Bombay from Zanzibar, the major portion of which is re-exported to England, and occasionally to France and Calcutta. Copal is liable to be confounded with *Animi*, when the latter is clear and good, but the solubility in alcohol furnishes a useful test—the *Animi* being readily soluble in this fluid, while Copal is sparingly so. Copal is also brittle between the teeth, whereas *Animi* softens in the mouth. Copal resin is possessed of peculiar properties, differing from most other resins in its very sparing solubility in alcohol; and of the little that dissolves with the assistance of heat the greater part is deposited as the solution cools. It is dissolved by ether and some essential oils. A substance resembling Copal is found mineral, and is called *Fossil Copal.* It is however insoluble in alcohol.—*Eng. Cyc. p.* 122.

(2853) COPPER. Venus of the Ancients.

Nehass. ARAB.	Miedz, POL.
Tung. CHIN.	Cobre, PORT.
Kobber, DAN.	Mjed Krasnoimjed, RUS.
Koper, DUT.	Tamra, Tamraka, SANS.
Cuivre, FR.	Cobre, SP.
Kupfer, GER.	Kopper, SW.
Thamba, GUZ. HIND.	Shemboo. TAM.
Rame, IT.	Tambran, TEL.
Cuprum, LAT.	Tambaga, MAL.
Miss, PERS.	

Copper was, with Gold and Silver, one of the most anciently known of the metals. It is abundantly diffused in nature, being found native as an Oxide, a Sulphuret, and as a Sulphate, Carbonate, Arseniate, and Phosphate. Copper is found in Persia, Sumatra, Borneo and Japan. Copper ore in the form of sulphuret is chiefly abundant in Ramgurh in Shekawattie: near Ajmeer the carbonate of copper is found in small veins, and in connexion with ores of iron.—*Genl. Med. Top. p.* 169. A silicate of Copper occurs in Nellore collectorate, but not in workable lodes. Copper ores are found in several

arts of Upper India, particularly in the Jeypoor ominions, and in the vicinity of Nejeebabab, nd Captain Hardwicke mentions, that, at Nag- ore and Dhumpore, places lying betwixt forty nd fifty coss and east of Sirinagur, two copper ines are worked during eight months of the ear. In lower Hindoostan, a copper mine was iscovered, some years ago, by Mr. J. B. Travers, hen Collector of the Ongole district, betwixt oodala and Ardinghie; which, for a short time, ttracted notice, but seems to have fallen into isrepute. The produce, as far as I can learn, s a variegated purple ore, containing a consider- ble portion of Iron, and Captain Arthur of he Corps of Engineers mentioned to Dr. Ainslie, hat the green carbonate of copper called Mala- hite, is a product of Travancore. The copper re of Japan is certainly the finest in the world, and is an article of trade from the island. Copper is also found in Thibet, in the Bur- mah dominions, in Nepaul, and in great abundance in Sumatra, where it is, by all accounts, combined with much gold. It would appear, by Le Gentil's description of the Phi- lippine islands, that this metal is common too in those delightful regions; where I cannot, how- ever, learn that white Copper is to be obtained; this singular mineral, seems peculiar to China and has been supposed, by the celebrated Dr. Black, to owe its distinguishing colour to an alloy of nickel.—*Ains. Mat. Med. page* 53. Dr. Helfer says, that the existence of copper on the Lampei Islands, the very first he supposes in this part of India as yet traced, is worthy of attention, and may lead to farther discovery of extensive veins of this ore." Mr. O'Riley states, " that specimens of copper ore have been brought from several islands of the Mergui Archipelago, and all obtained appears to be of the same character, viz. the grey copper ore, containing from forty to fifty parts of the metal in combina- tion with antimony, iron, and sulphur." He has also " traced the existence of the sulphuret of copper" on the Ataran; and Mr. Mason had a fine specimen of the green carbonate, or mala- chite, brought him by a Burman who said he re- ceived it from a Karen, who represented that it was found near the head waters of the Ataran; and other natives have assured him, that the same mineral exists up the Salwen. The blue carbo- nate of copper is seen in the same specimen unit- ed with the green carbonate. The natives say it is found in Province Amherst, but he has seen it only in specimens from Cheduba near the coast of Arracan.—*Mason.* Copper ores have been found in Sumatra, Celebes, and Timur. In the two former, mines of it are said to be worked, but if such be the case, even their locality has certainly never been shown. The probability is that this metal has always been, as it now is, im- ported. The prevailing name for it is tambaga, a corruption of the Sanscrit tamra.—*Crawfurd Dict. paye* 116. In the island of Borneo, it has been lately discovered, and it has been for a long time known to exist in Sumatra and Timur. The utensils made of this metal in those islands al- ways contain some iron, and the bars or cakes into which it is cast when sold for unalloyed copper, require much labor to make them pure and malleable. The copper found in Japan con- tains gold in alloy; it occurs in the market, in small red bars, six inches long, flat on one side and convex on the other, weighing 4 or 5lbs. each; this copper is the most valuable of any found in Asia. The Chinese and Dutch export upwards of 2,000 tons annually. South American copper is brought to the China market and from England and the United States, but it is scarcely ever landed; much of that in slabs is sent on to India and that in sheets, rods, and bolts is used by the foreign shipping. There is a natural alloy found in China, known under the name of *white copper*, which is used by the natives in great quantities, and prevents the consumption of foreign copper. The constituents are not known, but copper and iron are probably the chief. It is used for dish covers, candlesticks, tripods, plates, &c. &c., which when new and polished look almost as well as silver. Acetate of Copper (arugo, verdigris) is, like the sulphate, a com- mon bazar article in India, being imported chiefly from France. Verdigris is prepared on the large scale by strewing copper plates with grape husks. During the fermentation of the traces of sugar in the husk, the copper combines with oxygen, and the oxide with acetic acid formed by the grape sugar. The process is extremely tedious. We have made a very good article by using tamarind pulp instead of the grape.—*Beng. Phar. p.* 324.

(2854) COPPER, SULPHATE OF. CUPRI SULPHAS, *Cuprum Vitriolatum. Vitriolum Cæruleum.* Blue Vitriol. *Blue Stone.*

Sulphate de Cuivre, FR. | Kupfer Vitriol, GER.

The salt is produced naturally in the water of many mines. It was no doubt employed by the an- cients, as it was by the Arabs and Hindoos: by the latter it is called *neela tootia*, or blue vitriol. —*Royle.* The Sulphate of Copper (neela tutiya) is a common bazar article in India, being manu- factured in many parts of Bengal and the eastern Islands; it is easily prepared by heating copper to redness in contact with the air, removing the black scales which form, and dissolving these in dilute and boiling sulphuric acid, and crystaliz- ing. In the refining of silver it is incidentally prepared in very large quantities.—*Beng. Phar. p.* 322. Sulphate of Copper is much used in dyeing operations, and in the printing of cotton and linen; also for various other purposes in the arts. It has been employed to prevent dry rot by steeping wood in its solution, and is a power- ful preservative of animal substances; when imbued with it and dried they remain unaltered. It is afforded by the decomposition of copper

pyrites, in the same manner as green vitriol from iron pyrites. It is manufactured for the arts from old copper sheathing, copper turnings, and copper refinery scales.

(2855) COPPER-WARE and tutenague utensils, with *coral* and *glass beads*, all form a small portion of the Chinese trade to India; the Chinese seldom use glass beads as ornaments.

(2856) COPRA, DRIED COCOANUT KERNEL.

Copra, GUZ. HIND.	Narel, HIND.
Goabberekaya, TEL.	Coapparic tangoy, TAM.

The dried kernel of the cocoanut, from which cocoanut-oil is expressed; it is also used as an ingredient in curries by the natives of India. Copra is imported largely into Bombay from the Malabar Coast, and is occasionally re-exported to Calcutta.—*Faulkner*. It is the dried albumen, which when soft and pulpy is easily removed by a spoon.—*Seeman*. In preparing copra, the kernel of the cocoanut is taken out when fully ripe, divided in the middle and dried. Used as ingredient in curries and in medicine, and largely exported from India. The kernel of the cocoanut has much the taste of a filbert, and is a valuable ingredient in curries. It is considered by the Vytians as very nutritious. They conceive it to have the power of making the body corpulent.—*Ainslie*.

(2857) COPTIS TEETA. Wall, *Ranunculaceæ*. *Vern*. Mishmee Teeta, *Assamese*. Hong-lane. *Chinese*. Golden-thread root of Assam. The Coptis Teeta is a native of the mountainous regions bordering on upper Assam, and is in high repute among the Mishmee, Lanass, and Assamese. Dr. Wallich, in a paper in the VIIth volume of the Transactions of the Medical and Physical Society of Calcutta, informs us that quantities are sent down to Assam in neat little baskets with open meshes, made of narrow strips of rattan, and measuring 3 to 4 inches in length by 2½ in breadth, and 1½ in width; each basket contains about an ounce of small pieces of the root from 1 to 3 inches long. The roots are nearly cylindrical, and uneven, scabrous, more or less curved, of a greyish brown colour externally, internally bright yellow, varying in thickness from the size of a crow quill, to double that diameter. The root is perfectly dry and brittle, occasionally a few fibrillæ issuing from one end. The taste is intensely and purely bittery, very lasting, with only a slight aroma. On mastication the root tinges the saliva yellow. In North America the Coptis trifolia is much employed as a bitter tonic, and has been accurately described by Bigelow. The chemical properties of the American correspond exactly with those of the Assamese root, which contains neither tannic nor gallic acid, but abounds in a yellow bitter principle, soluble in alcohol and water. The root of the Coptis Teeta has found its way through the drug shops of Bengal, and is even occasionally exposed for sale in the upper provinces: it brings a very high price, and is deemed a tonic remedy of the greatest value. It was used extensively in the Calcutta General Hospital by the late Mr. Twining, who reported that its influence in restoring appetite, and increasing the digestive powers, were very remarkable, and that it might be said to possess all the properties of our best bitter tonics. Further trials in the Calcutta College Hospital were equally satisfactory. It did not seem to exercise any febrifuge virtue, but under its influence several patients recovering from acute diseases, manifestly, and very rapidly, improved in strength. The dose was 5 to 10 grs. of the powder, or an ounce of the infusion thrice only.—*O'Shaughnessy, pages* 162, 163. Latterly, Medical Officers in Assam, and amongst others have been Dr. Shurlock and the late Dr. Johnston Long, have had great faith in it, and have used it as a substitute for Quinine, both in remittent fever and in common agues. A tincture of Mishme Teeta is a bitter tonic, and its flavour and colour are much more agreeable than the tincture of Colomba.—*Beng. Phar. p.* 422.

(2858) COQUILLA NUTS are produced in South America, in the Brazils, by Attalea funifera, according to Martius, or the Cocos lapidea of Gartner; the latter title is highly descriptive. The plant might advantageously be introduced into Southern Asia. The coquilla nut shell is nearly solid: two separate cavities, each containing a hard, flattened, greasy kernel, generally of a disagreeable flavour: the cells occasionally enclose a grub or chrysalis, which consumes the fruit. The passages leading into the chambers are lined with filaments or bristles, and this end of the shell terminates exteriorly in a covering of these bristles, which conceal the passages; this end is consequently almost useless, but the opposite is entirely solid and terminates in the pointed attachment of the stalk. Sometimes the shell contains three kernels, less frequently but one only, and one coquilla nut has been seen entirely solid. The substance of the shell is brittle, hard, close, and of a hazel brown, sometimes marked and dotted, but generally uniform. Under the action of sharp turning tools it is very agreeable to turn, more so than the cocoa-nut shell; it may be eccentric turned, cut into excellent screws, and admits of an admirable polish and of being lackered. On the whole it is a very useful material, and suitable for a great variety of small ornamental works both turned and filed.—*Holtzappfel*. Seeman remarks that Coquilla nuts being excessively hard, beautifully mottled with dark and light brown, capable of taking a very high polish, they are extensively used for turnery work, especially in making the handles of Bell-pulls, small tops, the knobs of walking sticks, umbrellas and other articles.—*Seeman*.

(2859) CORACIAS, a genus of Birds belonging to the Insessorial or Perching division.

(2860) CORAL.

Pavalum, TAM.	Corail, FR.
Goollie, DUK.	Korallen, GER.
Busud, ARAB.	Murjan, Munga, GUZ.
Merjan, PERS.	Corale, IT.
Moonga, HIND.	Corallium, LAT.
Poalum, MALAY.	Coral, PORT.
Pagadum, TEL.	Korallu. RUS.
Birbat, SANS.	Vidruma, Prabala, SANS.
Bubalo, CYNG.	Coral. SP.
Koraalen, DUT.	*Faulkner. Ainslie.*

Mr. Faulkner says there are several varieties, of which the black is highly esteemed, and the red is next most prized; yellow and white corals are also met with. The value of coral depends upon its size, solidity, and the depth and brilliancy of its colour. Coral is found in great abundance in the Red Sea, the Persian and Arabian Gulfs, in various parts of the Mediterranean, on the Coast of Sumatra, in Japan, &c. It is imported into Bombay in the shape of beads from the Red-Sea, and overland from the Mediterranean.—*Faulkner.* Coral is brought to China from all the islands of the Indian Archipelago in native vessels, and is there wrought into many ornaments and official knobs or buttons. It sells from $ 40 to $ 60 per peeul according to the color, density, and size of the fragments. In former years, considerable quantities were imported in Company's ships from the Mediterranean, viâ England, but none for years past, nor is it likely to be again imported, which is the reason it is left out of the tariff.

(2861) CORAL PLANT. Jatropha multifida.

(2862) CORAL TREE.—Erythrina Indica.

(2863) CORALLINACEÆ, a family of Marine Plants belonging to the order *Algæ*. According to Harvey's definition it includes the *Corallinæ* and *Spongiteæ* of Kutzing, and the *Corallinidæ* and *Nulliporidæ* of Dr. Johnston.—*Eng. Cyc. page* 143.

(2864) CORCHORUS. A genus of plants belonging to the natural order Tiliaceæ.—*Engl. Cyc.* See JUTE. Wight describes corchorus acutangulus, capsularis, humilis, and prostratus.

(2865) CORCHORUS CAPSULARIS. This species is one of the plants from which the Jute of India is prepared.

(2866) CORCHORUS FUSCUS. This annual affords a strong and abundant fibre, springing up about Rangoon in the rainy season and mostly found growing along with *Urena*, but not to the same extent. It affords a strong fine grey fibre—*McClelland.*

(2867) CORCHORUS OLITORIUS.

Bhunghe, BENGALEE. | Phetwoon, BURM.

An annual plant common in Bengal. There are two varieties, the green (Pat, *Beng,*), the reddish, (Bun-pat, *Beng.*) both are used for their fibres, which are called *jute* and *pat.* A coarse kind of cloth (*tat*) is woven from the jute, and affords the materials of the well known gunny bags. An infusion of the leaf is much employed as a fever drink among the natives of the Lower Provinces, and Mr. Twining mentions the practice with approbation in the 2d. vol. of his admirable work on the diseases of Bengal.—*O'Sh. page* 229. The Bunghi of Bengal grows wild about Rangoon during the rainy season, and probably also in other districts, though not to the extent that *Urena* does. The plant might of course be cultivated to any extent. The fibres of the bark is the jute of Bengal.—*McClelland.* The leaves of this plant are used in Egypt as a pot-herb, and, under the name of Nurcha or Sag Greens, they are in common use amongst the natives of India.—*Jaffrey.* It will be seen from the above that Jute, Jew's Mallow, is the product of *Corchorus olitorius* and *capsularis* of the family *Tiliaceæ*. Fibre Jute (Sans., *Putta*; Beng. *Pat*; fibre, *Jute*; cloth, *tat, chotee, megila. Gania*, Amboynese, *Rami Tsjina*, Malay, *Oimoa*, Chin is now so familiarly known, and is so extensively employed in some of our manufactures, that one is apt to think that it must have long been established as an article of commerce. This is far from being the case, for we find no notice of it even in comparatively recent dictionaries of commerce; and it is not above fifteen years since that it has come to be much employed in the manufactures of Britain though it has long been so employed in India, and its fibres much used there for making both cordage and cloth. Under the name of Jute, however, the fibre of two very distinct plants is included, though no recent accounts of these, have been published by any of the present growers of Jute. Both plants are common in almost every part of India; the leaves of both are used as pot-herbs, and the stems of both yield fibre, and are cultivated on both these accounts; and both are placed by botanists in the genus Corchorus, which is so named from the *Korkhoros* of the Greeks, which also was a pot-herb, and, indeed, is by many supposed to have been one of the very plants which we now describe. This is the species called *Corchorus olitorius*, which is still cultivated in the neighbourhood of Aleppo, and is described by travellers in the East as eaten for a pot-herb in Egypt and Arabia, as well as in Palestine. Rauwolf saw the Jews about Aleppo using the leaves as a pot-herb; hence the old name of "Olus judaicum" in old authors; which by the French is translated Mauve de Juif, and by us "Jew's Mallow." It is supposed to be the plant alluded to in 'Job,' xxx, 4. 'Mallauch,' in Kitto's 'Cyclopædia of Biblical Literature.' It is the same plant which, small and herbaceous in the dry soil of Syria, grows to a height of four or five feet in the North of India; but in the hot, moist climate of Bengal, attains a size that allows fibres of twelve feet in length to be separat-

CORCHORUS OLITORIUS: JUTE.

ed from it. The other plant, which we suppose also yields some of the Jute of commerce, is *Corchorus capsularis*, easily distinguished from the former by the form of its seed-vessels being globular instead of elongated and cylindrical. It is also more remarkable for an east and west, than for a north and south distribution. We have stated that it is to be found in most parts of India, and likewise in Ceylon. It is curious that Rumphius, in his 'Herb. Amboinense,' v. 212, t. 78, describes it under the name of Ganja (but this may be pronounced Gania), which is that applied in India to the true Hemp. By Malays it is called *Rami Tsjina*, that is, Chinese Rami; a name which is also applied by them to other fibre-yielding plants, as to the true Hemp, according to Rumphius, and also to the *Urtica nivea*, as we have seen under the head of China-grass. It is no doubt cultivated in China, where Roxburgh states it is called *Oi moa*. This so-called Chinese Hemp—but a true Corchorus—was at one time supposed to be superior to the true Hemp, and attempts were made to introduce it into England; the account of which is detailed in the 'Phil. Trans.,' vol. lxxii. It is there stated, that seeds sown in England produced plants fourteen feet high, and nearly seven inches in circumference, though few produced mature seeds. Some, however, which came to maturity in the second season produced a crop of good Hemp, greater by one third than was ever known to be obtained in England. We may easily believe, therefore, that this may grow to a great height in the congenial climate of Bengal. As both those plants seem to yield the fibre called Jute, though already noticed under their respective heads, we may again describe both, before proceeding to treat of their culture or the mode adopted by the natives of India for separating their fibre. *Corchorus olitorius*, Pot-herb, or Jew's Mallow, as seen in the Mediterranean region, is an herbaceous annual plant, only a foot or two, but in India of several feet, in height, and erect in habit. The stem is smooth, cylindrical, and more or less branched. The leaves are of a lively green colour and smooth, alternate, on footstalks, oval or ovo-lanceolate in shape, with the margin dentate, and with the two lower dentilures terminated by a slender filament. The stipules are simple, awl-shaped, and reddish coloured at their base. The peduncles or flower-stalks are one to two-flowered. The flowers are small, having the calyx consisting of five pieces or sepals, and the corolla of five yellow petals. Stamens numerous. Torus, or nectary cup-shaped, with glands at the base of the petals. Ovary solitary, ripening into a long, nearly cylindrical capsule, ten-ribbed, six to eight times longer than it is broad, five-celled, and formed of five valves, with five terminal points. Seeds numerous, with nearly perfect transverse partitions between them. This is called *Puti* in Sanscrit, and *Pat* in Bengalee: flowers in the rainy season, and fructifies in October and November. Cloth made of it is called *Tat*, the fibre *Jute*. Dr. Roxburgh states that there is a reddish variety of this, which the natives call *Bun Pat*, that is Wild Pat. *Corchorus capsularis*, or Capsular Corchorus, is also an annual, with a straight, smooth, and cylindrical, afterwards branched stem, from four and five to eight and ten feet in height. The leaves have long footstalks, and are oval, acuminate, thin, and of a light green; serrated at their margins, with the two lower serratures terminating in narrow filaments. The flowers are small, yellow, and like those of the other species in the number of their parts. The capsules are short and globose, wrinkled and muricated, with five cells, and composed of five valves: seeds few in each cell, and without transverse partitions. It flowers in the rainy season, and the fruit is ripe in September and October. This is the *Ghi-nalita pat* of the Bengalese, and its fibre sometimes called *Nalta jute*. It is called *isbund* in North-West India. It has been called Chinese Hemp (*Rami tsjina*) by the Malays, and its fibre *China pat* by Roxburgh. The kind called *Teetah* pat is said to be a variety of this species. It is cultivated both in Bengal and in China, on account of its fibre, which is separated by maceration, and used as cordage, both for agricultural purposes and for river navigation, as well as for making paper. It is also employed for making the coarse kind of cloth called Megila in Bengal; and another kind called *tat* or *choti*, whence, probably, has been derived the name *Jute*. This kind of cloth is now well known by the name *gunny*, and used for making *gunny bags*; a name derived either from the Ganja or Gania of Rumphius, or from *goni*, a name of *Crotalaria juncea* on the Madras side (Buchanan); there the name Jute is in some places applied to its fibre, and also to that of *Hibiscus cannabinus*. There are several other species of Corchorus common as weeds in every part of India, but all may easily be distinguished from the last by the roundish form of its capsules. Dr. Royle found species at as great an elevation as 5000 feet in the Himalayas, but only in the rainy season. Dr. Buchanan found both the above species cultivated in the districts of Dinajpore, Rungpore, and Purneya. In the last he was informed, that the Corchorus which is used for cordage is the species called by botanists *olitorius*, while that used as a pot-herb is the *capsularis*; just the reverse of what is the case in some other places, showing the probability of both species being cultivated indifferently for their fibres. The fibre is long, soft, and silky and well fitted for many of the purposes to which Flax is applied, as it is divisible into very fine fibrils, which, like those of the other species, are easily spun. It is possessed also of some strength and durability, even after 116 days'

CORCHORUS OLITORIUS: JUTE.

maceration, as in Dr. Roxburgh's experiments. Under the microscope, the fibres of the two species seem exactly alike. It is generally stated that the fibres of Jute, or of those employed in making gunny bags, cannot be bleached. This is incorrect; they may not be bleached by ordinary methods. Indeed, a paper-maker mentioned to Dr. Royle, having discovered Jute in some rope, because it would not bleach. But the late Col. Calvert brought several specimens of beautifully bleached Jute to the India House, as well as some furniture damask made of it: and we observe that Mr. Rogers presented some of his bleached specimens to the Agri-Horticultural Society, in May, 1846. Dr. Roxburgh has described the species *C. olitorius* as the Pat of the Bengalese, and as partially grown for the leaves and tender shoots, which are used by the natives —both Hindoos and Mahomedans—as an article of food. When wild, it shoots out many lateral branches, which renders it a difficult matter to separate the fibres from the woody parts. In preparing the filaments, the plant requires much longer steeping in water than Hemp—a fortnight or three weeks being scarcely sufficient for its proper maceration. (*v.* p. 248.) He called attention to it as a substitute for Flax, from the length and fineness of its fibre. The gunny bags, in which sugar and similar commodities are brought to Europe from India, are made of this material. These are now sent to America for packing their cotton. Though only made known in the beginning of the century, it is now imported in immense quantities, and used for a variety of purposes, as it spins so easily, and being cheap, is therefore used for mixing. It was formerly employed for mixing with Codilla; this is now used for mixing with Jute. A description of the cultivation and manufacture of Jute was given by Baboo Ram Comul Sen (in 'Trans. Agri-Hortic. Soc.,' vol. ii, p. 91), where he mentions that the principal places where it is cultivated are Malda, Purnea, Natore, Rungpore, and Dacca—where both land and labour are cheap. He mentions four kinds—*Pat*, *Tasa*, *Mestah*, and *Coshta*—but without describing them; and quotes Roxburgh's descriptions of *C. olitorius*, *C. capsularis*, and *C. fuscus*. Other names are given in other districts, as at Jungypore: 1, *Ghore Sun*; 2, *Paut*; 3, *Cooch-murda Paut*; 4, *Amleeath Paut*. The first and fourth may be Crotalaria and Hibiscus, and the second and third species of Corchorus. These may also be included under the names of *Amrah Sun*, *Chunduna Sun*, and *Putooa Sun*. Some Jute sent to the Exhibition of 1851, from Rungpore, was distinguished by the names of Suffed (white) Hemanty Pat; 2, Lal (red) Hemanty Pat; and 3, Lal Petrie Pat.

Culture.—The seeds are sown in April or May when there is a sufficient quantity of rain to moisten the ground, which is generally low, and harrowed in the same manner as paddy (rice) land (in any land that will produce summer rice, which requires to be well ploughed and smoothed). The field is weeded after the plants are a foot and half high. When it has flowered, which happens about July and August (to 14th Sept.,—B.), it is cut. The plants are three to twelve feet high, and the circumference of the stalk is about one inch. As the seed is not ripe when the plants are cut, some of them are left to allow the seeds to come to maturity. After the plants are cut down close to the roots, their tops are clipped off, and fifty to a hundred are tied together; ten to fifteen of these bundles are laid in a shallow tank or reservoir of water, like rafts, over which a quantity of turf and clods of earth are laid to make them sink under the surface of the water; it is allowed to remain there for eight or ten days, during which the cultivator daily visits it, in order to see that it is properly laid, and the trunks are not unduly rotted. When the bark separates, and the stalk and fibres become soft, the weight upon the raft is removed, and the stalks are unbundled. The dresser descends into the water knee-deep, and takes up five or eight sticks at a time. He breaks off two feet of them at the bottom; the bark, which is become soft like thread, is held in both hands, and the stalks are taken off. The fibres thus separated (and by mere washing are brought to the state of separated fibres,—B.), are dressed, and exposed to the sun, by hanging the bundles of fibres over bamboos to dry; they are afterwards partially cleaned, and finally made up into bundles of from one to two maunds for the market. After the Pat has been removed, the fields of which the soil and elevation are suitable grow a winter crop of tobacco or mustard seed. The produce is differently stated to be from 400 lb. to 700 lb. per acre. The harvest price, according to Dr. Buchanan, was, in his time, about 12½ annas per 100 lb. Mr. Henley informed Dr. Royle that "Jute used to be sold some years ago for R. 1 8 for the bazar maund; but the demand in Britain has had the effect of raising the price of Jute to double its old Indian value. At present, any fine, long, silky Jute is eagerly bought up at Rs. 2 8; still for inferior Jute I should say, dealing face to face with the village dulals, the price would not exceed R. 1 8 per bazar maund." The culture of Jute has of late years been greatly improved in many places, as may be seen in much of that sent to market, and of which we have an instance in sample of a Jute presented for report by Mr. P. Carter of Bhojepore Factory to the Agri-Horticultural Society. This having been submitted to the members of the Flax Committee, the following favorable opinions have been expressed on it: Mr. Hodgkinson says,—This is the finest specimen of Jute I have ever seen—being bright, clean, strong, and of excellent

staple; the root ends particularly well freed of the hard woody bark which characterises bazar Jute, and deteriorates its value. I should say that £16 to £17 could be obtained for Jute of similar quality at home, being fully £2 per ton more than the ordinary descriptions now fetch. Mr. Fergusson says--It is very good Jute, worth £3 to £4 per ton more than what is generally shipped. Dr. Buchanan and Ram Comul Sen describe the Pat as spun by two kinds of spindles, the Takur and Dhara. A bunch of the raw material is hung up in every farmer's house, or to the protruding stick of a thatched roof, and every one who has leisure, forms with one or other of these spindles, some coarse packthread (sutoli), of which ropes are twisted for the use of the farm. The Dhara is a reel, on which a thread when sufficiently twisted, is wound up. The Takur is a kind of spindle which is turned upon the thigh or the sole of the foot. Ghurghurea is a third kind of spinning machine. It is only the lower Hindu castes, called Rajbongsi, Konget, and Polya, that form this packthread for being woven into sackcloth, and spin a finer thread from which the cloth called Megili, or Megila, is woven. By far the greater part of the cloth that is used dyed, receives the colour in the state of thread. The coarse cloth, called Megili, is woven by the women of the lower class of people. Most families have a loom, and the people, especially the women in the afternoons, work a little occasionally, and this serves to clothe the family. The pieces consist of three or four narrow cloths sewed together, some four or five cubits long, and from two to three cubits wide, and are worth from two to eight annas each. Some have red and black borders. It is said to be more durable than cloth made of cotton. Since the foregoing remarks were written by Dr. Royle, he has been favored with the following remarks from Mr. Henley. The plant in question is by far the most extensively cultivated of all the fibrous family throughout the delta of Bengal. Its easy culture, rapid growth, and comparatively large produce present advantages not to be overlooked by that eminently practical and economical people, the natives of Bengal. Had it combined along with these advantages, the qualities of strength and durability, it would probably have superseded all other fibrous materials; but, rapid in its growth, it is again remarkably rapid in its decay—being in fact the most perishable of fibres. It is generally grown as an after-crop, during the rainy season, on high land, or land not subject to submersion, like rice land. A hot and moderately rainy season suits it best; excessive rains or bad drainage injure and deteriorate it. In this point of view it is a precarious and delicate crop; otherwise it presents the advantage of affording a more valuable return from land at that season, than any other crop which the cultivator can employ. It is sown broadcast, requires careful weeding when young, but soon acquires strength enough to keep off all intruders. The young leaves are eaten by the natives as a sort of spinach; they have, however, a coarse, weedy flavour, little suited to our European palates. No plant is more grateful for good cultivation than the one in question, in a good, loamy soil, well manured, or which has been well manured under a former crop. It attains a height of ten or twelve feet, with stems of three quarters of an inch in diameter. A poor crop, or one which had suffered from excessive rains, would have a height of only from three to six feet. The crop being ripe, the stems are cut down close to the roots, made up into bundles, and laid to steep in some neighbouring ditch, where lumps of mud are placed on them to keep them submerged. Here they are carefully watched from day to day, the operator trying the bark with his nail, until he finds the decomposition arrived at the proper point. In preparing Jute intended for export, he will push the water-retting process to its utmost limits, short of actually destroying the fibre by excessive putrefaction. This is done in order to obtain that thoroughly detached silky character of fibre, according to which it is valued in the export market. Such Jute has always suffered more or less in strength.—Jute or Paut prepared for native consumption is much more durable than that prepared for export. It is likewise cheaper, as the yield per acre is much larger. It is much darker coloured, and not so clean. The natives are very particular in the selection of Jute for such purposes as pack-saddle bags for their transport oxen; or for their store-grain bags—great packages of six or eight feet diameter, erected on bamboo stages, and looking like our European brewery tuns. There are also a multitude of manufactures in this fibre, many of them possessed of considerable strength, some again of very fine texture. To return to our water-retting process. The proper point being attained, the native operator, standing up to his middle in water, takes as many of the sticks in his hand as he can grasp, and removing a small portion of the bark from the ends next the roots, and grasping them together, he strips off the whole with a little management, from end to end, without breaking either stem or fibre. Having prepared a certain quantity into this half state, he next proceeds to wash off: this is done by taking a large handful; swinging it round his head he dashes it repeatedly against the surface of the water, drawing it through towards him, so as to wash off the impurities; then, with a dexterous throw he fans it out on the surface of the water, and carefully picks off all remaining black spots. It is now wrung out so as to remove as much water as possible, and then hung up on lines prepared on the spot, to dry in the sun. Jute is never so beautiful as at the first moment of its preparation; for such is

CORCHORUS OLITORIUS: JUTE.

its proneness to decay—a true eremacausis of Liebig—that it changes colour from day to day, gradually descending from the beautiful pearly white, through shades of fawn colour and brown, with proportionate loss of strength. These changes, also, are occasioned or accelerated by causes which hardly affect other fibres; hence, one of the difficulties of bleaching, and the tendency to become brown, of all fabrics consisting of this material. That portion of the hank of fibre next the root, or where it has been held in the hand, being always more or less contaminated with bark and impurities, is cut off for about nine inches. These ends are sold to the paper-makers and for mixing and making up various thick, coarse fabrics, of which whole cargoes, amounting to tens of thousands of pieces, are now annually taken off by the Americans from Calcutta, for cotton bagging and similar purposes, forming an entirely new trade. The manufacture of Jute whiskey from these ends was tried experimentally, by subjecting them to the process of conversion into sugar with sulphuric acid, and afterwards fermenting. The produce had much resemblance to grain whiskey. But the great trade and principal employ of Jute is for the manufacture of Gunny chuts or chuttees, *i. e.*, lengths suitable for making bags. This industry forms the grand domestic manufacture of all the populous eastern districts of Lower Bengal. It pervades all classes, and penetrates into every household. Men, women, and children find occupation therein. Boatmen in their spare moments, husbandmen, palankeen-carriers, and domestic servants; everybody in fact, being Hindoos—for Mussulmans spin cotton only—pass their leisure moments, distaff in hand, spinning Gunny twist. Its preparation, together with the weaving into lengths, forms the never-failing resource of that most humble, patient, and despised of created beings—the Hindoo widow—saved by law from the pile, but condemned by opinion and custom for the remainder of her days, literally to sackcloth and ashes, and the lowest domestic drudgery in the very household where once, perhaps, her will was law. This manufacture spares her from being a charge on her family—she can always earn her bread.—Amongst these causes will be discerned the very low prices at which Gunny manufactures are produced in Bengal, and which have attracted the demand of the whole commercial world. There is, perhaps, no other article so universally diffused over the globe as the Indian Gunny bag. All the finer and long stapled Jute is reserved for the export trade, in which it bears a comparatively high price. The short staple serves for the local manufactures, and it may be remarked, that a given weight of Gunny bags may be purchased at about the same price as a similar weight of raw material—leaving no apparent margin for spinning and weaving. The stems or stalks of the Jute crop are of almost equal value with the fibrous portion. They are beautiful white and straight stems, of a light, brittle wood, somewhat like willow switches, and have a multitude of uses amongst the natives, such as for the manufacture of charcoal for gunpowder and fireworks, for the formation of fences and enclosures, for pea and similar cultivation, and for the construction of those acres of basket-work which the traveller may remark near every native village. These are the enclosures in which the betel-pepper vine is cultivated, the leaf of which is universally consumed by the million—peer or peasant. These stems have another extensive employ which cannot be passed unnoticed—that of furnishing a peculiar quality of fuel suited to the native process of careening boats on the banks of the rivers. Great flaming fires may be observed at night under the bottoms and sides of the native craft; men running to and fro with bundles of flaming faggots, applying them assiduously, as if they were occupied in trying to burn the craft. Looking at the structures themselves, built up of mats and thatch, and appearing like slovenly, ill-conditioned hay stalks, that an accidental spark would ignite, it appears surprising that such a determined effort should not produce that result. The only object, however, is to effect the destruction of the myriads of worms or teredæ, which, if not destroyed, would in a very short time have eaten up the whole fabric. Bengal Jute has now attained such an important position in the commerce of the world that any suggestion for its improved production merits attention; and there can be no doubt but that the application to it of the process of preparing the fibre without water-retting, would effect the most signal improvement in its qualities. Such could never make it equal to Flax or Hemp; but the method would increase the qualities of strength and durability, and fit it for all purposes in which moisture took no part, for to this agent it is peculiarly obnoxious. In reference to this point it may be worth noticing, that in cases in which it is desirable to ascertain the amount of Jute adulteration in such fabrics as sail-cloth (in which it appears to me to be a highly criminal fraud), a very good test may be found in high-pressure steam. A piece of such sail-cloth, kept for four hours in steam of 30 lbs. pressure, lost on simple washing thereafter, 22 per cent.—the decomposed Jute actually washing out, and with little injury to the remaining fabric. Besides being used in India and exported to England, it is sent to America, and will probably be required on the Continent of Europe but it is necessary for the people, if they wish to retain or extend their trade, to keep up the quality of their produce, which is complained of in the following extract from a letter from America to Dr. Royle. "The article of Gunny bagging for cotton is imported largely into this country

from India; in fact, is superseding all other descriptions of cloth for that purpose. I have been asked several times what it is made of, and where manufactured. On both points I am ignorant, and should be much obliged if you will give me the information. It is superior to and liked better than any other bagging; but the manufacturers are already commencing to make it inferior, by mixing ordinary (Indian) Hemp or tow with it. They will spoil their market unless they desist from such practices, for the planters will not use an inferior, if they can procure a good article." *Georgia, 15th April*, 1853. Some of the Jute lately imported into England has been twelve feet in length, in bales of about 4 cwt., bound round with Gunny cloth. The exports of Jute have already been alluded to when referring to the great increase which has taken place in this trade. Many other Indian fibres are possessed of equally good properties in some respects, and of very superior ones in others, and which require only to be known to be very generally appreciated in Europe.

JUTE, GUNNY CLOTH, AND GUNNY BAGS EXPORTED FROM CALCUTTA, IN THE YEAR 1850-51.

Exports.	Jute.	Gunnies and Gunny Cloth.
To United Kingdom, ...	Ms. 768,945	Nos. 69,636
„ France, ...	13,931	—
„ Hamburgh, ...	128	2,180
„ North America, ...	9,242	2,290,427
„ Coast of Coromandel, ...	598	1,955,150
„ Malabar, ...	—	2,054,075
„ Penang and Singapore, ...	—	1,043,600

„ Arabian and Persian Gulfs,	—	4,000
Total..	Mds. 793,299	9,035,713
Value...	Rs. 1,970,715	Rs. 2,159 782

The following statement shows the proportion of Gunnies and of Gunny Cloth; and also that a decrease took place in the former, and an increase in the latter in the two years given:

Exports from Calcutta.	1849-50.	1850-51.
Gunnies, ...	12,961,441	8,759,185
Gunny Cloth, ...	238,039	276,528
Total...	13,199,480	9,035,713
Value....	Rs. 2,683,551	2,159,782

Besides these there were exported from the Madras Presidency 58,950 gunny bags; but there is reason to believe that these are made of *Sunn* or *Crotalaria juncia*. Bombay being on a small island, cannot export any of its own growth; but as Gunny cloth is much required for packing cotton, it is imported in large quantities, as 167,820 pieces, valued at Rs. 397,097 (but in 1849, to the value of Rs. 548,384), from the United Kingdom, Ceylon, East Coast of Africa, and Soumeeanee, but chiefly from Calcutta; also from Cutch, Malabar, and Canara, Aden, Sindh, Concan, and Guzerat. But we also find the places mentioned after Calcutta as those to which Gunny cloth was exported, but not in any quantity, except 296,757 pieces to the Concan—the whole export for that year amounting to 391,279 pieces, and the re-exports to 3,403,453, valued at Rs. 468,177, therefore greatly exceeding the imports, and hence probably including some brought by the Causeway. The kind of cloth called *chatee* is made from the same material, and is made of three different kinds, and always woven in pieces from three quarters to one cubit wide, of which two or three are sewn together into one piece before it is sold. The first kind, intended for bedding, is from four to five cubits long, and from two and a quarter to three cubits wide, and sells at about 8 rupees per 100 pieces. Secondly, that intended for covering bales of cloth is of the same dimensions, but is thicker than the former kind. The 100 pieces cost from 6 to 10 rupees. Thirdly, that intended for making rice and sugar-bags is four cubits long, and one and a half or one and a quarter cubit wide, and ten bags cost 4 or 5 rupees. These are sewed or doubled and made into bags. The value of the manufacture in the Dinajepore district amounted to 160,000 rupees. (Buchanan.) The principal places where Chatees are manufactured are Malda, Purnea, Natore, Rungpore, and Dacca; where the cultivation of Jute is extensive, and the price of labour and land very cheap. Ram Comul Sen says, "If the labour of spinning the Jute and weaving Chatee, are to be done according to the rules of labour at Calcutta, the price of gunny would be more than double that for which it is sold." The greater part is cultivated by those who use or manufacture it; for almost all the small Hindu farmers weave cloth of this material, and every farmer requires some for the use of his farm. On all the eastern frontier a great proportion of the women are clothed in the coarse cloth made of the Corchorus, which also gives them much employment. The value of the material consumed in those days was about 70,000 rupees. In the cold weather the poor cover themselves by night, and often by day with a sackcloth rug; and the rich usually put one under their bedding. Some is required for the packing of tobacco and for some grains, but much even in those days was exported to Calcutta, Patna, and other places.

In the north-west port of Bengal a great porportion of the people used to be clothed with Megili or Pata. Specimens of this Pat clothing were sent to the Exhibition of 1851.—*Royle, Fibrous Plants, pages 240 to 252.*

(2868) CORDAGE.

Touw-werk, Dut.	Russee, Hind.
Manœuvres, Cordage, Fr.	Caolame, It.
Tauwerk, Ger.	Jarcia, Cordaje, Sp.
Doodah, Guz.	

A term used in general for all sorts of cord, whether small, middling, or great. Coir cordage is largely manufactured on the Malabar Coast, and the Laccadive and Maldive Islands, and is the kind in general use in rigging native craft, &c. Cordage of excellent quality is manufactured in Calcutta: the principal of the fibrous plants of Southern Asia are as follows:—

Abelmoschus esculentus, ...	Vendee fibre.
Abelmoschus ficulneus, ...	
Abutilon indicum, ...	Toottee.
Abutilon polyandrum, ...	
Abutilon tomentosum, ...	
Acacia leucophlœa, ...	Oody nar.—This tree is common near Cape Comorin. The fibres from the bark are used by the fishermen in making nets. A coarse kind of cordage is also made from it.
Acacia indicum, ...	Karoovalum nar.
Agave americana, ...	Pita fibre or great Aloe.
Agave vivipara, ...	Kathalay.
Ailantus malabaricus, ...	Poroomarum.—Inner bark. Not much used.
Aloe indica, or vulgaris, ...	Kuttally nar.
Aloe perfoliata, ...	Aloe fibre.
Ananassa sativa, ...	Pine Apple fibre.
Andropogon schœnanthus,	Camachy.
Antiaris saccidora, ...	Arengee.
Bauhinia racemosa, ...	Malthun.
Bauhinia diphylla, ...	
Bauhinia Vahlii, ...	Yepy tree bark.
Bauhinea tomentosa, ...	Vellay Aatee nar.
Baehmeria; several species,	
Borassus flabelliformis, ..	Palmyra fibre.
Butea frondosa, ...	Brown hemp.
Callicarpa lanata, ...	Thondy nar.—Inner Bark. Not much used.
Calotropis gigantea, ...	Ak, Mudar, or Yercum.
Cannabis sativa, ...	Hemp.
Chamœrops or Hemp palm,	
Crotalaria juncea, ...	Canamboo or Wuckoo.—Cultivated extensively in the Southern districts. It is not exported. Fishing nets are made from them; the best kinds are grown in the Northern districts of Travancore.
Cordia obliqua.....	Pothooveroosen nar.—Moderate strength.
Crotalaria juncea, ...	Sunn (wuckoo nar.)
Crotalaria tenuifolia, ...	
Cocos nucifera, ...	Cocoa.
Corchorus olitorius, ...	Jute.
Corchorus capsularis, ...	
Cyperus textilis, ...	Mat-grass, or Coaray.
Decaschistia crotonifolia, ...	
Dœmia extensa, ...	Ootrum ka bel.
Eriochlœna Candollii, ...	
Eriodendron anfractuosum,	Bast.
Erythrina indica, ...	
Ficus religiosa, ...	Arasa nar.
Ficus racemosa, ...	Atti nar.
Ficus indica, ...	Aulamarum nar, Aallen nar. —Not much used.
Ficus oppositifolia, ...	Bodda nar.
Ficus mysorensis, ...	Kul-aallun nar.—Not much used.
Fourcroya gigantea, ...	Seemay Kathalay.
Girardinia Leschenaultiana,	Neilgherry nettle.
Gossypium indicum, ...	Indian Cotton.
Gossypium acuminatum, ...	Brazil Cotton.
Grewia asiatica, ...	Bast.
Grewia tiliæfolia, ...	
Grewia rotundifolia, ...	Oonoo.--Moderate strength.
Guazuma tomentosa, ...	
Hibiscus cannabinus, ...	Poolychay fibre.
Hibiscus sabdariffa, ...	Roselle fibre,
Hibiscus vesicarius, ...	Wild ambara.
Hibiscus rosa chinensis, ...	Shoe plant fibre.
Hibiscus vitifolia, ...	
Hibiscus lampas, ...	
Hibiscus macrophyllus, ...	
Isora corylifolia, ...	Valumbrikai, Kywen nar. This is the most valuable fibre in Travancore. The plant grows abundantly at the base of the hills. It is from the stem of this shrub that the natives produce fibre.
Linum usitatissimum, ...	Flax.
Mimosa Intsia, ...	Eenjy nar.
Musa paradisiaca, ...	Plantain fibre.
Pandanus odoratissimus, ...	Fragrant Screw Pine.
Paritium macrophyllum, ...	
Paritium tiliaceum, ...	
Rhaphis, ...	
Saccharum sara, ...	Sara.
Sanseviera zeylanica, ...	Moorghee, or Marool.
Salmalia malabarica, ...	Elavum parooty.
Sesbania cannabina, ...	
Sida populifolia, ...	Used for Cardage &c.
Strychnos potatorum, ...	Katha vennar.
Smilax ovalifolia, ...	Krinkoddy nar.—Used for tying bundles &c.
Sterculia guttata, ...	
Sterculia ornata, ...	
Terminalia alata, ...	Mooroothen nar.—Bark, very strong and lasts many years: used for dragging timber, cordage &c. Common in the forests.
Terminalia belerica, ...	Umburathee nar.
Tylophora asthmatica, ...	Koorinja.
Vernonia anthelmintica, ...	Coat seeragum.
Yucca gloriosa, ...	Pita or Adam's Needle.
Yucca aloifolia, ...	

In the Tenasserim Provinces, as in other parts of India, cordage is made of coir, the outside shell of the cocoa-nut, but ropes are more frequently made from the bark of three different trees belonging to the genera hibiscus, paritium, and sterculia, viz, Paritium macrophyllum and P. tiliaceum; Hibiscus macrophyllus, Sterculia guttata and Sterculia ornata.—*Mason.*

(2869) CORDIA, a genus of Plants belonging to the natural order *Cordiaceæ*. It has a tubular calyx, 4-5 toothed. Corolla funnel shaped or

campanulate with a flat 5-7 cleft limb, and a hairy or naked throat. Stamens 5, short, inserted in the throat of the corolla. Style protruding, bifid, with 4 stigmas. Ovary 3-4 celled. Drupe containing 1 stone with 1 or 3 cells, two of which are usually abortive.—*Eng. Cyc. page* 146. In the southern part of the Peninsula, the Tamil name, Narvillie marum, seems to be applied indiscriminately to three or four species of the genus, Cordea Rothii, Icon. 1379, Cord. obliqua, Icon. 1378, Cord. fulvosa, Icon. 1380, *Borragineæ*, so that it is impossible to say which is the one meant by it. Cordea obliqua, C. Rothii and C. fulvosa have all been brought to Dr. Wight, under this name. He believes the wood of all is very inferior, the trees being usually small.—*Wight.* Dr. Wight gives in his Icones, Cordia cuneata, 1379; domestica, 1378; fulvosa, 1380; Leschenaultii, 1380; Myxa, 1378; obliqua, 1378; Perrottettii, 1381; Rothii, 1379; serrata, 469; tomentosa, 1378; trichostemon, 1380; and Wallichii, 1378.

(2870) CORDIA ANGUSTIFOLIA.

Goondnee, Hind.

This tree is from 30 to 40 feet high, the wood is very tough, used for carriage poles, &c., fruit the size of a large pea, round and smooth, the pulp yellow, and gelatinous, the tree is common throughout the Deccan.—*Riddell.* Dr. Buchanan, in his 'Journey through Mysore,' mentions that ropes are made of the *Narweli*. Naravali Fibre, which is the *Cordia angustifolia*, and which he found common near Severndroog. Its fruit is esculent, but tasteless. The plant belongs to the same family as the Sebestens, formerly famous in medicine; but which, when ripe, seems only remarkable for containing much mawkish mucilaginous pulp. It is possible that the bark of some of the species, when young, may yield a useful fibre.—*Royle. Fib. Pl. page* 11.

(2871) CORDIA LATIFOLIA. Roxb. Fl. Ind. i. p. 588.

Buhooari, Beng. | Burra Icsoora, Hind.—*O'Sh. p.* 497.

Broad-leaved Cordia. The tree is common at Ajmeer, is found in Hindostan, but mostly confined to the southern parts of India.—*Royle. C. latifolia* has numerous spreading and drooping branches; the young shoots angular and smooth. The general height of trees ten or twelve years old about 20 feet.—*Eng. Cyc. p.* 146. The fruit is eaten: "phaleetas" or slow matches are made of the bark. This tree is hardy and ornamental, and would do well in compounds along with other trees.—*Gen. Med. Top.* The wood is very inferior, and of small size. Under the name Sebesten Plums, Sebestans, or sepistans, two sorts of Indian fruit have been employed as pectoral medicines, for which their mucilaginous qualities, combined with some astringency, have recommended them. They are believed to have been the *Persea* of Dioscorides. Linnæus has erroneously applied the name of Sebesten to an American species of this genus which is not known in medicine.—*Eng. Cyc. page* 146.

(2872) CORDIA MYXA. Roxb. Fl. Ind. i. p. 500. *Syn* Sebestena officinalis.

Vidi marum, Tam.	Buhooarie Beng.
Kendal, Jav.	Lesura, Hind.
Lebuck, Avicenna.	Nekra, Tel.
Mochayet, Forskal,	Bukampadáruk a. Sans.
Lolu, Cyng.	

A native of many parts of India, Persia, Arabia, and Egypt, and common throughout the Concan. The trunk is generally crooked, from 8 to 12 feet high, and as thick or thicker than a man's body. The bark gray, cracked in various directions. Branches numerous, spreading, and bent in every possible direction, forming a dense shady head. The flowers are numerous, white and small.—*Eng. Cyc. page* 146. The fruit of *Cordia Myxa* has been long used as a medicine under the name of Sebistans or Lobestens. *C. latifolia* is supposed to produce the larger, *C. Myxa* the smaller variety of this article. The bark is deemed a mild tonic. That of *C. angustifolia*, Roxb. (Goondnee) is much used for making astringent gargles. The dried fruits are very glutinous in the fresh state. They are slightly laxative, but it is especially as a pectoral that they are esteemed in India. In Java the fruit is used in gonorrhœa and ardor urinæ; 12 drachms of the pulp are said to be equal in aperient effect to the same quantity of cassia pulp. The seeds of Cordia Myxa, are called *Chakoon ke beenge*, and deemed an infallible remedy in ringworm, the powder mixed with oil being applied to the eruption.—*O'Shaughuessy, p.* 498. The smell of the nut when cut is heavy and disagreeable; the taste of the kernels is like that of filberts. It is the true Sebesten of the European Materia Medica. The fruits according to Roxburgh, are not used in the Circars medicinally, but when ripe are eaten by the natives, and also most greedily by several sorts of birds, being of a sweetish taste. The wood is soft, and of little use except for fuel. It is reckoned one of the best kinds for kindling fire by friction and is thought to have furnished the wood from which the Egyptians constructed their mummy cases. The wood is said by Dr. Royle to be accounted a mild tonic.—*Engl. Cyc. page* 146.

(2873) CORDIA OBLIQUA. Willd.

Narroovallay pullum, Tam.	Lasora. Hindooee.
Goudnee, Duk.	Seloo, Sans.

This is a large handsome tree, common in the lower provinces of India, with a small, round, reddish colored, pleasant tasted, but glutinous, fruit—*Ainslie page* 228.

(2874) CORDIA SERRATA. Saw-leaved Cordia. Gab, Gad, Gondori, Hind.

This species is common in hedges at Ajmeer.

The small gummy berries are eaten as a fruit by the poor.—*Genl. Med. Top. page* 184.

(2875) COREOPSIS. The bright yellow flowered coreopsis, which derives its name from the resemblance of its seeds to an insect, is uncommon in Tenasserim gardens.—*Mason.*

(2876) COREOPSIS, Varieties. Are annuals well worth cultivating in India either in pots or the flower garden: raised from seeds, should be sown at various times during the cold months for the purpose of obtaining a succession of bloom, sown in February; they may be had in flower during the hot months, if attended to with water, at which season any flower is acceptable.—*Jaffrey.*

(2877) COREOPSIS TINCTORIA. *Compositæ.* There are several varieties of this elegant flower. The leaves have a strong scent of fennel. The colour of the flower is a deep orange yellow striped with red. The seed may be sown at the commencement of the rains, or at any time after. It requires no particular care beyond other border flowers.

(2878) CORGE. Twenty pieces of Cloth.

(2879) CORIANDER SEED.

Kezeerah. Arab.	Dhunnia, Guz. & Hind.
Dhunia, Beng.	Coriandri semina, Lat.
Cotum-barroo, Cyng.	Mety, Mal.
Cottimbiry, Can.	Kushneez, Pers.
Coriander, Dut.	Coentro, Port.
Coriandre, Fr.	Dhanyaka. Sans.
Koriander Saamen, Ger.	Cottamillie, Tam. & Tel.

The fruit or seed of an annual plant (*Coriandrum sativum*), cultivated in Suffolk, Essex, Kent, in Great Britain, and the Levant, Tartary, South of Europe, and in parts of India. When fresh, their smell is strong and disagreeable, but by drying it becomes sufficiently grateful. They are used as an ingredient in curries in India, and medicinally as a stimulant and stomachic. The seeds are procurable in all Indian bazars. In Europe, Coriander seed is chiefly used by distillers to produce an aromatic oil. The quantity imported annually into Britain does not exceed 50 tons, and it is brought principally to the port of Hull. —*Simmonds.* At the Madras Exhibition of 1855, *Coriander*, *Aniseed* and *Cummin* were largely exhibited from several collectorates.—*M. E. Juries Reports.*

(2880) CORIARIA NIPALENSIS. (Vern. *Mussooree*) from its abundance, has bestowed its name on that well known hill station in the Himalayas. It is also common in Nipal. The fruit formed by the junction of several pistils is eaten in the hills, although that of the European species is poisonous, inducing narcotism and tetanus. The leaves of *Coriaria myrtifolia* have been used in France for the adulteration of senna, and have occasioned some fatal accidents. All parts of these plants are very rich in the astringent acids, and are consequently much employed by dyers.—*O'Shaughnessy, page* 270.

(2881) CORIARIACEÆ a vey small natural order of Gynobasic Polypetalous Exogenous Plants. The two genera, of which alone the order consists, are nearly allied to *Rutaceæ*, but their leaves are not dotted.—*Eng. Cyc. p.* 148.

(2882) CORIANDRUM, a genus of Plants belonging to the natural order *Umbelliferæ.*—*Eng. Cyc. p.* 147.

(2883) CORIANDRUM SATIVUM, Coriander plant.

Duniya, Beng.	Duniah, Duk. Hind. & Can
Kushneez, Pers.	Coriander, Coriandrum sativum, Lin.
Kuzeereh. Arab.	Damaka, Sans.
Cottamillie, Tam.	*Ainslie's Mat. Med. p.* 263.
Dhana, Guz.	

C. sativum is found in the corn-fields of Tartary, the Levant, Greece, Italy, and south of Europe.—*Eng. Cyc. p.* 147. It is grown in every part of Southern Asia, where the leaves are used by the natives for chatnies and curries, the seeds in decoction, sweetmeats; of easy culture; raised from seed: will grow in any good soil. The fruit is carminative and aromatic. Cullen considered it more powerfully corrective of the odour and taste of senna than any other aromatic. (Lindley, 'Flora Medica.')—*Engl. Cyc. page* 147. During the unripe state, the odour resembles that of bugs, but this changes rapidly as ripening proceeds. Fée derives coriandrum from χορις, *a bug*, on account of the factor of the young seeds.—*O'Shaughnessy, page* 371. Coriander Fruit, or seeds as they are incorrectly called, are used in sweetmeats, in certain stomachic liqueurs, and in some countries in cookery: they are little esteemed in England.—*Engl. Cyc. page* 147.

(2884) CORK.

Kork, Kurk, Vlothout, Dut.	Sughero, Suvero, It.
Liege, Fr.	Suber, Lat.
Kork, Ger.	Cortica, Port.
Bhooj Guz. Hind.	Korkowoe derewo, Rus.
	Corcho, Sp.

The outer bark of a species of evergreen oak (*Quercus suber*), abundant in Portugal, Spain, Italy, the south of France, Corsica, and other countries. It is light, porous, compressible, and elastic. Corks, floats for nets, and other articles are cut and shaped out of the bark. Cork, botanically considered, is a soft and elastic layer of bark which becomes remarkably developed in the kind of oak inhabiting Spain and Portugal. This substance is developed in other plants, but in none in so large quantity as in the *Quercus suber.* As soon as the bark dies it ceases to grow, and then, not distending as it is pressed upon from within, it falls off in flakes which correspond to the layers that are formed annually. These flakes are the layers of cork which the Spaniards collect under the name of the outer bark, while the inner living bark is or rather should be spared. We are told

however by Captain Cook that the Spaniards have been in the habit of stripping off the inner bark also, although it is of no value except for tanning, and although its removal destroys the trees. The same intelligent observer states that the cork-tree occurs in Spain throughout the whole extent of the Tierra Caliente, but it is most abundant in Catalonia and Valencia, whence the principal exports have been made.—*Engl. Cyc. page* 148. At the Madras Exhibition of 1855, two specimens of cork were exhibited, one good, from the "Western Coast Jungles," and another inferior from Coimbatore, the trees producing the samples were not mentioned. The deeply cracked spongy bark of the "*Bignonia suberosa*" (country-cork tree) yields an inferior kind of cork.—*M. E. J. R.*

(2885) CORN.

Korn, Dan.	Frumentum, Lat.
Graanen, Dut.	Zboze, Pol.
Bleds, Grains, Fr.	Graos, Port.
Korn Getreide Ger.	Chljeb, Rus.
Dhan, Guz. Hind.	Granos, Sp.
Biade Grani, It.	Sad, Spannmal, Sw.

The grain or seed of plants separated from the spica or ear, and used for making bread, &c. Such as wheat, rye, barley, oats, &c. *Faulk:*

(2886) CORNELIAN, Agate, Carnelian.

Achaat, Dut.	Agata, It.
Agate, Fr.	Achates, Lat.
Achat, Ger	Agat, Rus.
Akeek, Guz. & Hind.	

A genus of semi-pellucid gems. It takes a very high polish, and its opaque parts usually present the appearance of dots, eyes, veins, clouds, zones, or bands. Its colours are yellowish, reddish, blueish, milk-white, honey-orange, or ochre-yellow, flesh-blood, or brick-red, reddish-brown, violet-blue, and brownish-green. The most beautiful agates found in Great Britain are the *Scotch Pebble*, which are met with in the mountains of Cairngorm, by which term they are distinguished. Cornelians are also obtained in Germany, Siberia, Ceylon, some parts of the Cape of Good Hope, but the principal agate mines are situated in the province of Guzerat. From the latter place they are brought to Bombay in the form of beads of various shapes and sizes, small square cut pieces, (which are chiefly re-exported to China), rings, brooches, studs, cups, and a variety of other ornaments.—*Faulkner.* Cornelians, agates, and other stones of greater or less value are purchased by the Chinese for manufacturing into official insignia, rings, beads, and other articles of ornament; they are brought to China chiefly from India or Central Asia.—*Williams.*

(2887) CORNUS CAPITATA. Caprifoliaceæ.

Bhumowra, Hind.

This genus of plants consists of large trees and shrubs, the bark of the C. florida and sericea are said to be most excellent tonics.—*Riddell.*

(2888) CORNUS. Several species of this genus have been found in the Himalayas, in Sylhet, and Nipal, by Drs. Wallich and Royle; these are the Cornus oblonga, in the Deyra Doon; C. macrophylla, and C. nervosa, Mussoorie; and Cornus capitata, Wall., (Benthamia fragifera, Lind.) at a still higher elevation.—*O'Shaughnessy, p.* 375. The fruit of *Benthamia* is eaten in the hills, and from the seeds of some species an oil is expressed.—*O'Shaughnessy, p.* 375. Wight, in Icones, gives figure of Cornus altera, 1211, sylvestris, 1211, and Zeylanica, 1210-11.

(2889) COROMANDEL or CALAMANDER WOOD. This is the produce of a Ceylon tree of great size, having a dingy ground, and sometimes running into white streaks. It is used in cabinet work, like zebra and rose wood, to which it has some resemblance.—*Faulkner.* Tredgold mentions that the figure is between that of rose-wood and zebra-wood; the colour of the ground is usually of a red hazel brown, described also as chocolate brown, with black stripes and marks. It is said to be so hard as almost to require grinding rather than cutting, this is not exactly true, as the veneer saws cut it without particular difficulty: it is a very handsome furniture wood and turns well; it is considered to be a variety of ebony. Mr. Laird says there are three varieties of Coromandel; the Calamander or Coromandel, which is the darkest, and the most commonly seen in England; the Calemberri, which is lighter coloured and striped, and the Omander, the ground of which is as light as English yew, but of a redder cast, with a few slight veins and marks of darker tints. He says, the wood is scarce and almost or quite limited to Ceylon; that it grows between the clefts of rocks, this renders it difficult to extract the roots, which are the most beautiful parts of the trees. The Calamander wood tree is Diospyros hirsuta, and Kadum Beriya is D. Ebenaster, according to Moore's Catalogue of Ceylon Plants, and therefore of the same genus as the true Ebony.—*Holtzappfel.*

(2890) CORONILLA. Two species are described, having cathartic leaves and juice.

(2891) CORONILLA GRANDIFLORA. Willd.

Its greens.

Aghaty kai, Tam.	Avisic kaia, Tel.
Aghaty ke pullie, Duk.	Aghastia, Sans.

The slender long legume of this plant is eaten by the natives who dress it in various ways. The tree in Malay is called Turi.—*Ainslie page* 236.

Its leaves.

Aghaty keeray, Tam.	Coronilla grandiflora,
Aghaty ke baujie, Duk.	Lin.
Avisee koora, Tel.	Aghastia, Sans.

This tree is commonly planted to support the Betel vine. Rheede tells us in his Hortus Mala-

baricus that an infusion of its leaves is given on the Malabar coast, in cases of catarrh. *Vide Hort. Mal. par.* 1. *page* 96 —*Ainslie, p.* 252.

(2892) CORONILLA PICTA (Flore purpureo.)

The plant.

Carin Chembie, TAM.	Purple Flowered Coronilla ENG.
Nulla Somuttie, TEL,	Kristnah Rajum, SANS.

This is a plant held in high estimation by the Tamools as well on account of the great beauty of its delicate purple flowers as from the virtues, the leaves are said to possess : these are invariably employed when they can be obtained in such cases as require poultices to hasten suppuration which they form by being made warm and mixed with a little castor oil. The leaves smell like fresh clover, and are food for cattle.—*Ain's. Mat. Med page* 75. Poultice of Nutceya Leaf prepared as Nim leaf poultices, are favourite external emollients among the native practitioners.—*Beng. Phar. page* 390.

(2893) COROSOS, OR IVORY-NUTS, are produced by Phytelephas macrocarpa, growing in central America and Columbia, (Humboldt.) They are described as seeds with osseous albumen ; the tree is a genus allied to the Pandaneæ, or screw Pines, and also to the Palms. The nuts are of irregular shapes, from one to two inches diameter, and when enclosed in their thin husks, they resemble small potatoes covered with light brown earth : the coat of the nut itself is of a darker brown, with a few loose filaments folded upon it. The internal substance of the ivory-nut resembles white wax rather than ivory ; it has, when dried, a faint and somewhat transparent tint between yellow and blue, but when opened it is often almost grey from the quantity of moisture it contains, and in losing which it contracts considerably. Each nut has a hole, which leads into a small, central, angular cavity ; this, joined to the irregularity of the external form, limits the purposes to which they are applied, principally the knobs of walking sticks, and a few other small works.—*Holtzappfel.*

(2894) CORRÆA. RUTACEÆ. The species of this genus are mostly shrubs, the flowers white and scarlet, each plant requires a tolerable space to grow in, as it attains the height of six or more feet, and should be placed in a shrubbery where the soil is good.—*Riddell.*

(2895) CORROSIVE SUBLIMATE, BI-CHLORIDE OF MERCURY,

Ruscapoor, GUZ. HIND.	Doppelt chlorquecksilber, GER.
Bi-chlorure de Mercure,	Hydrargiri Bi-chloridum, LAT.
Sublime corrosif, FR.	

Is white, with an acrid metallic and persistent taste, without smell. It is met with in small crystals, on in semi-transparent masses. Corrosive sublimate is made in Surat, and seems to have been long known to, and prepared by the natives of India.—*Faulkner.*

(2896) CORTINARIUS EMODENSIS, of the Rev. M. J. Berkeley, who has named and described it from Dr. Hooker's specimens and drawings.—*Hooker Him. Jour. Vol.* ii. *page* 47. It is a large mushroom, the "Onglau" of Thibet : it forms a favorite article of food.

(2897) CORUNDUM. ADAMANTINE SPAR.

Samada, GUZ. HIND.

Several substances differing considerably in colour, and sometimes in form, but nearly agreeing in composition are classed together under the name of *Corundum*, which is that given to the common variety by the natives of India.—*Engl. Cyc. p.* 151. This stone is, with the exception of the diamond, the hardest substance known. It is generally of a pale-gray or greenish colour, but sometimes of red and brown tints. It is found in India, China, and in some parts of Europe. The Indian variety is whiter than the Chinese, and is considered the purest. In India it is used for polishing steel, and cutting precious stones ; it is always procurable in the bazars.

Common Corundum. This variety, usually called *Adamantine* spar, occurs, like the sapphire and Ruby, commonly in the secondary form of 6-sided prisms, but usually much larger. It is sometimes nearly colourless, and rather translucent ; it presents great variety of colour, but is most commonly greenish or grayish ; occasionally brown or red, rarely blue. Although its most common form is the 6-sided prism, it occurs, though rarely, also in acute and obtuse double 6-sided pyramids. On account of its extreme hardness it received the name of Adamantine spar. It occurs in China, Bengal, Malabar, Tibet, the Carnatic, &c. It is used in the East Indies for cutting and polishing precious stones, and also granite and other hard rocks that are employed in the temples and other public monuments. According to Chenevix the Carnatic Corundum contains silica, but this does not appear to be constant.—*Engl. Cyc. page* 151.

Emery. This substance which, when reduced to powder, is much used for polishing hard bodies, though very different in appearance from the preceding, is on account of its hardness and an analysis, regarded as Amorphous Corundum. Its colour is usually gray ; its lustre is somewhat glistening. Its specific gravity is about 3·66 to 4 ; it occurs massive, and is granular. It is principally imported from the island of Naxos in the Grecian Archipelago, and was found by Mr. Smithson Tennant to consist of,

Alumina, ...	86
Silica, ...	3
Oxide of Iron, ...	4
	— 93

It occurs also in Italy, Spain, and Saxony; in Asia minor, India and America, and it is said, in small quantities, also in Wicklow, Ireland.—*Eng. Cyc. page* 152.

Ruby. Colour blood-red or rose-red, sometimes a tinge of violet; primary form as above, and generally occurs in 6-sided prisms. It is not so hard as the Sapphire, and is more readily cleaved. Like the Sapphire, it consists of pure alumina. "The largest oriental ruby known was brought from China to Prince Gargarin, governor of Siberia; it afterwards came into the possession of Prince Menzikoff, and constitutes now a jewel in the Imperial Crown of Russia." (Dana.)—*Engl. Cyc. page* 151.

Sapphire, of which there are several varieties, the names of which are dependant chiefly upon their colour: the *White Sapphire,* which is transparent or translucent; the Oriental Sapphire, which is blue; *Oriental Amethyst,* which is purple; the *Oriental Topaz,* yellow; the *Oriental Emerald,* green: and some other varieties occur, as the *Chatoyant* and the *Opalescent Sapphire.* —*Engl. Cyc. page* 151.

Prismatic corundum or chrysoberyl, is found among the Tora hills near Rajmahal on the Bunas, in irregular rolled pieces, small and generally of a light green colour: these stones are considered by the natives as emeralds, and pass under the name of "punna," but the natives are aware that they are still softer than the real emerald of India (which is generally green-coloured sapphire). —*Gen. Med. Top. page* 160. *Corundum pebbles* are found in "the gem-sand of Ava river;" and they probably exist in the sands of some of the rivers in the Tenasserim provinces. The common emery is a variety of this species.—*Mason.* In Coimbatore two very different minerals pass under the common name of corundum, the one is true corundum of lameller structure, the other softer and amorphous, but chrystature in its composition, apparently some form of hornblend. The mineral is abundant in the district and easily procured at a small cost. The corundums in the Madras Presidency are not unworthy of notice. Their applications, as grinding and polishing materials, are well known to the people who use them in mass or mixed in lac. The implements prepared by the latter process are in the form of discs for laps, or wheel grindstones; used by cutlers, &c., also in the form of whets and hones and ragstones for sharpening the finer and coarser cutting implements used by farriers, &c. The Native workmen, cutlers, &c., often do not distinguish garnets from corundums calling both of these emery, though the differences between the three minerals are so marked, it is difficult to understand how they can be confounded. The corundums of Southern India are the more deserving of notice, because they seem to replace the emery of other countries; at least I am aware of only one author who has alluded to the occurrence of emery in Southern India, and the Madras Museum does not contain any substance that Merchants would regard as identical with the Turkish or Grecian emery of commerce. The meaning or origin of the word is not very apparent: the Mahomedans call it "corund" or "corunj" stone, and the Hindoos know it by a somewhat similar name. The first specimens sent to Europe were forwarded by the late Mr. Anderson to Mr. Berry, a lapidary in Edinburgh, as the substance used by the people of India to polish masses of stone, crystal and all other gems, except the diamond, and it was then examined by the celebrated Dr. Black, who from its hardness named it adamantine spar.—*Vide Adamantine Spar.* Corundum and its varieties, viz., Sapphire, Corundum and Emery are only surpassed in hardness by the diamond. They belong to the same class of minerals, and the emery of commerce which is so extensively used in Europe and imported into England for grinding and polishing metals, glass. &c,, is supposed to be a mere variety of corundum, a mixed granular corundum; a mechanical mixture of corundum and oxide of iron, the iron in some of the varieties amounting to 33 per cent.

In the mixed corundums of Greece and Turkey the iron seems equably diffused through the mass imparting to it a bluish grey colour; but in the specimens which have reached the Madras Museum from Southern India the corundum and ore of iron, though occurring together, are not mixed, but remain apart, segregated, the corundum forming one side of a mineral and the oxide of iron, in a lump or lumps on the other side; and all such masses are magnetic and possess polarity.

Emery. Of the different varieties of emery used in the arts that of Naxos is still preferred, as it is more uniform in its quality than that from Pulah and Gumuch: but it is believed that if the best qualities of Nicarian emery be found in abundance and such only sent to the market, they prove equal, if not superior, to the emery of Naxos. That from Naxos is of a dark grey colour with a mottled surface and with small

points of a micaceous mineral disseminated in the mass. It frequently contains bluish specks or streaks, which are easily recognised as being pure corundum. When reduced to powder it varies in colour from dark grey to black, but the colour of its powder affords no indication of its commercial value. The powder of emery examined under the microscope shows the distinct existence of the two minerals, corundum and oxide of iron. The specific gravity of emery is about 4, but its hardness is its most important property in its application to the arts; and those emeries which contain the least water, everything else being alike, are the hardest. The silica is usually in combination with alumina, or the oxide of iron, or both, so that the quantity of alumina must not be regarded as an indication of the quantity of corundum in the emery. In addition to the component substances of emery, others, as titanic acid, oxide of manganese, oxide of zirconium, and sulphur, occur in some of the emeries, but in very minute quantities. These remarks have been made with the hope that the corundums of India may be found suitable for all the purposes to which emery is now applied. The only difference in corundum seems to be the absence of oxide of iron, but there does not seem to be any quality given to the mineral by its presence in emery, essential to its value in the arts. This is a point however that I write with diffidence on. In Europe, where machinery is so available, there could be no difficulty in preparing corundum powders of the requisite degrees of fineness, and its preparation in this country would perhaps be the only difficulty to be overcome. There can be no question of the great cheapness of corundum. Emery at the end of the last century was selling at from £7 to £8-10 per ton, and between the year 1820 and 1835, it fell to even less than this: but a monopoly being allowed, it rose in 1846 and 1847 to £40 a ton. The discovery of other mines however at Gumuchdagh near Ephesus has caused a great reduction since then, and the selling price in London has been from £10 to £25 a ton. What prices the several corundums of India might bring in the London market it is difficult to say. There is no reason why the picked corundums should sell for less than the finest emeries, and Captain Newbold mentions that the corundums near Gram, when sorted into the three sorts known in commerce, viz. the *red*, the *white*, and the *scraps* of these two, are sold to the Arab merchants at Mangalore and Tellicherry at prices from twelve to fifteen or thirty rupees the candy equal to £4, £6, and £12 a ton. Corundum seems to occur in abundance in several parts of the peninsula of India, in North Arcot, Cuttack, Coimbatore, Guntoor, Mysore, Salem and Hyderabad. The authority for its existence in North Arcot, is a specimen in the Museum of the clove-brown variety, labelled from Naggery, and for its occuring in Cuttack and Coimbatore, the statement of the late Captain Newbold, who mentions Gudjelhutty and Chennimully as the places where it is found in Coimbatore, but does not specify the locality in Cuttack. The occurrence of corundum in the Guntoor Collectorate, was first made known to the community generally by the Madras Exhibition of 1855, and Mr. Rohde, who exhibited the specimens, remarked on them as follows:—"I am "desirous that the attention of the Agency "Houses should be called to the specimens of "red corundum, I send. If I mistake not, ex- "perienced jewellers would pick out stones "suited for common jewellery from it, and "the refuse cannot be worth less than £15 "and £20 a ton at home." The other district which the Madras Exhibition of 1855 showed to be producing corundum was the kingdom of Hyderabad, from which was received a very excellent sample of picked stones, possessing an irregularly chrystalline structure. Salem and the Mysore country, however, have been the longest known as containing corundum sites, some of which were described at some length by the late Captain Newbold, who mentions its occurrence in the neighbourhood of Gram, a village and fort in the Mysore country about ninety-eight miles westerly from Bangalore, and lying between the latter place and the Western Ghauts. The mines which Captain Newbold named, being about forty-five miles north by west from Seringapatam and about seven or eight east by north from the fort of Gram. But judging from the specimens in the Madras Museum there have been some other sites discovered since then, and the following places may be named as sites in Mysore where corundum occurs:—

French Rocks, Captain Loudon, in Madras Museum.
Golhushully, in the division of Nooghully, Newbold.
Kulkairi, in the division of Chinrayapatam.
Burkunhull, in the division of Chinrayapatam, Newbold.
Kundeo, in the division of Chinrayapatam, Newbold.
Erdgunkul, in the division of Chinrayapatam, Newbold.
Norhik, in the division of Narsipur, Newbold.
Deysani Carbonhully, in the division of Banawaram, Newbold.
Appianhully, in the division of Harnally, Newbold.
Nullapardy, on the road to Bangalore, Madras Museum.
Mundium, in the Astagram division, Madras Museum.
Cuddoor, in the Nuggur division, Madras Museum.
Nuggur, in the Nuggur division, Madras Museum.

Professor Thomson is quoted by Captain Newbold as mentioning (Outlines of Mineralogy, volume 1, p. 213) that "the corundum occurs in imbedded crystals in a rock which consists, according to Count Bournon, of indianite, and contains felspar, fibrolite, several varieties of augite, and also octohedral iron ore; the hair brown or reddish brown varieties are called adamantine spar. They occur with fibrolite and octohedral iron ore in a sort of granite containing no quartz." And again (p. 256) he states, that "fibrolite is a mineral found accompanying crystals of corundum in the Carnatic, and that it is a component part of the granite, which is the matrix of the corundum of China." Professor

Jameson, in his Geognosy of Peninsular India (Ed. Cab. Lib. No. VIII, pp. 349-50) gives a summary of what is known regarding the corundum of Southern India, and states that it occurs embedded in granite, and sienite in the district of Salem, in the Madras Presidency, associated with cleavelandite, indianite, and fibrolite; but near Gram at Golhushully and Kulkairi, at which the best corundum is said to be obtained, the mineral was found to occur in decomposed beds of a talcose slate, to which gneiss is subordinate, associated with nodules of indurated talc, and of a poor quartzy iron ore; asbestus, chlorite, actinolite, and schorl were found in the talcose slate. In the Salem district also Newbold mentions that this mineral occurs embedded in gneiss and a greyish earth resulting in part from the disintegration of that rock. The places named by that inquirer and the sites from which the specimens in the Museum have been received, are as follows:—

Nammaul Viralmodos.—On the north bank of the Cauvery, in the Permutty talook.—Newbold.

Sholasigamany, (probably *Scholaserameny*). Trichingode talook, near the village in a low hill in great abundace.—Newbold.

Caronel, Aupore, Mallapollye and at various localities up the river Cauvery as far as *Corcoambodi*, where it is dug by the natives in the fields, and there are remains of many ancient excavations still to be tracted.—Newbold.

Gopaulchetty pollium, 50 miles north of Salem.

Talaneegerry, Madras Museum.

Coundapady, Madras Museum.

Rubies. Captain Newbold also mentions that fine rubies have from time to time been discovered in many of the corundum localities just enumerated, associated with this gem, particularly in the gneiss at Viralimodos and Sholasiramany, and the natives informed him that it occurs in the Trichingode talook and at Mallapollaye, though comparatively speaking rare. Passing, says Captain Newbold, last year through Gram, a village and fort in the Mysore country, about ninety-eight miles westerly from Bangalore, between it and the Western Ghauts, I was informed by the Natives of the place that corundum (corund ka pathar) was found in this vicinity; at Golhushully, in the division of Noogyhully; at Kulkairi, Burkunhulli, Kundeo, and Yedgunkul, in that of Chinrayapatam; at Norhik, in Narsipur; at Deysani Curbonhully, in Banawaram, and at Apyianhully in that of Harnhully. The localities I visited were Golhushully and Kulkairi, at which places the best corundum is said to be obtained. The mines lie about forty-five miles north by west from Seringapatam, and about seven or eight east by north from the fort of Gram. The formation around Gram is gneiss, associated with protogene. Proceeding from it in a westerly direction, the northern shoulder of the insulated range, south of the village of Belladaira, running nearly north and south, is crossed, and the soil suddenly changes from a light sandy colour to a deep red. The surface of this swell is covered with fragments of a ferro-siliceous schist, with quartz in alternate layers. As night was coming on, I was not able to examine this mountain-range; but from its singularly sharp outline, the elevation and shape of its highest peak, and its direction conformable with that of the primary schist, I should say it was, probably, a large ferruginous quartzose bed, in the gneiss, associated with quartzy iron ore, fragments of which are seen at its base. The Natives have a tradition that gold was formerly got from this hill, which is not at all improbable, as it is found in similar gangue near Baitmungalum, sixty-one and a half miles east from Bangalore, and at Malliyalum, near the south west border of Mysore in Coimbatore. Minute grains occur in the sandy bed of a brook there. A little farther west, where the talus of the mountain subsides into the plain, the gneiss reappears, alternating with talc slate in nearly vertical strata. The dip, as observed in an adjoining nullah between the mountain and the village of Belladaira, is to the east by north, and the direction of the strata N. 22° east. The corundum mines of Golhushully lie four or five miles north-east of this place, and those of Kulkairi about a mile farther. The surrounding country is a succession of smooth slightly convex plains, except to the south-east, where the gneiss rises above the soil in a rocky ridge, terminating in a knoll about 700 yards to the east by south of the mines to which it descends, rising again into a slope to west northwest of the mines, on which lie fragments of a light brown compact quartzy iron ore. Nearly at the bottom of this slope are the mines, from which the ground descends on both sides, to the north-west to a tank, and towards the south-east to the village of Golhushully, about a mile distant. Between the mines and this village, near the bottom of the ascent on which they are situated, runs a nullah, the bed of which gives a tolerable section of the strata resting on the gneiss. The first (No. 1) commencing from the surface is a thin sandy alluvial soil; next (No. 2) succeeds a dark brown gritty soil, apparently decomposed ferruginous quartz, but sometimes sandy, from two to three feet thick. Below this we see the detritus (No. 3) of the subjacent gneiss; the quartz veins of which, remaining undecomposed, are observed penetrating into the substance of the soil from below. Some of the veins are broken by the superincumbent weight, aided by their own approach to decomposition. The quartz and felspar veins contain nests of a disintegrating blackish mica. The direction of the beds of gneiss is S. 10° E. with a dip of 60° a little to the N. of E. The surface of the ascent from Golhushully to the mines, except where the blocks of the brown ore above described, and a few edges of talc slate crop out,

is covered with dark brown soil (No. 1, Sec. 2) containing small particles of iron ore, and the broken up veins of the subjacent rock to the depth of about three feet: below this lies a bed (No. 2) varying from one to two feet in thickness, of chert, angular and rounded fragments of a poor quartzy iron ore, nodules of a whitish, highly indurated talc, talcose quartz, and felspar. A variety of schorl occurs imbedded in an indurated brownish talc, generally in three-sided prisms: it fuses into a lighter coloured enamel than the European specimen in my cabinet. This schorl has a shining lustre; fracture uneven breaks easily across the axis of its prisms; opaque, streak grey, scratches glass and quartz, the latter with difficulty. In this bed the best kinds of corundum are found. Below this is a bed (No. 8) of greenish earth, evidently of decomposed talcose slate: it is slightly greasy to touch, and falls to pieces with a hissing noise when put into water. Before the blowpipe in the platinum forceps it melts partially into a brownish slag, covered with minute globules of a white enamel, streak slightly coherent, shining, approaching earthy; adheres slightly to the tongue, and emits an argillaceous odour when breathed on. It is traversed by veins of a compact talc in laminæ which in some places bear traces of dislocation. The red earth and a quartzy ferruginous paste in small reniform and pisiform nodules, resembling those of hæmatite, are found intermixed with the more decayed portions of the schist. Beds and veins of white earth are also found in it, occupying the bottom of some of the excavations, as at Kulkairi. These are composed of talc, quartz, and minute particles of the corundum of which the vein is the gangue; streak and fracture earthy; feels gritty, and slightly greasy; adheres slightly to the tongue; does not emit so strong an argillaceous odour as the green earth; falls to pieces when put into water with a hissing noise. Before the blowpipe, fuses partially and with difficulty into a whitish enamel. The corundum is imbedded both in this earth and that arising from the decomposed talcose schist; the whiter fragments occur sometimes as hexagonal prisms tapering off to the extremity. The locality can be easily distinguished by the external appearance of the crystals, those found embedded with the iron ore having a ferruginous covering, whilst those found in the white talcose earth present a white or greyish appearance. Microsopic particles of corundum occur disseminated in this earth, more numerous in some parts than others, as if coverging to certain central foci of molecular aggregation. In fact, the whole of the component parts of the surrounding talcose slate appear to be separating from their combined state, and about to enter into some new form. Disintegration in the interior of certain rocks, whether from heat, cold, moisture, electricity, or other cause, seems to be, in some cases, a preparatory stage in Nature's mystic laboratory to matter assuming new forms; and under certain relative conditions we find the same agents that caused their decomposition, actively operating in their re-aggregation. Heat and electricity are powerful dispersive and aggregative agents. For familiar illustration, I need scarcely point to the flame produced by the blowpipe reducing at one point a metal to dust, and at another restoring the dust to its metallic state. By the judicious application of heat nearly solid particles can be made to move through and converge in the centre of a nearly solid mass, as exemplified by the experiment of Breislak, who succeeded in forming a nucleus of a variegated copper in the centre of a mass of pure copper pyrites, by subjecting it to a heat below that of fusion. Decomposition, however, is not an absolutely necessary condition for the production of adamantine spar, as I have seen it in canular nests in gneiss but little disintegrated. The talc schist is sometimes hardened and consolidated by contact with the iron ore, as seen in blocks thrown out of a mine near the foot of the ascent. Both the chert and a dark red ferruginous jasper are used by the Natives as flints. Salt springs occur in the vicinity. The wells about Gram were, I am told, both sweet and brackish within a short distance, and I picked up a fragment of a rock-salt in the green earth of the mine. This is to be accounted for by the nearly vertical position of the strata between which they find their way towards the surface. A little to the east of Kulkairi I crossed a low plain nearly covered with a white travertine, partly compact, partly cellular, resembling that found in the bed of the Cavery at Seringapatam.

Mines of Kulkairi.—The corundum mines at Kulkairi are situated both near the summit, and at the foot of the rising ground there. There are a series of excavations, vaying from two to twelve feet in depth, sunk perpendicularly through similar strata to those just described. The corundum is thrown out, cleared, and separated by the miners into four classes, viz., the red, the white, the scraps of both, and the refuse. The three first form the article of commerce, which is carried to Mangalore and Tellicherry; and, according to my Native informants, there sold by the contractor to the Bombay and Arab merchants, at prices from twelve and fifteen to thirty rupees the candy, according to its quality. A very large quantity (2,000 bags) is now (January 1837) lying at Tellicherry unsold, owing to a disagreement about the price between the contractor and the merchant. The present contractor for corundum in Mysore is a Lingayet, named Bussetti, an inhabitant of Bowenhulli, in the talook of Arculgode; his contract has almost expired, and, in consequence, no miners are at work. He took the mines for two years, for which he was to pay

the sum of 530 Canteray pagodas. The former contractors paid 500 for two, or 250 for one year; consequently it may be supposed that the produce has risen in value. These mines were only opened about seven or eight years ago by a native, named Hari Ram. I need scarcely add, the corundum is used by natives, pounded as emery, to polish precious and other stones, particularly granite and basalt. It is also mixed for this, and other purposes, with melted lac, in fine and coarse powders, as we use a mixture of glue and sand. It is said to be found at Mundium in Mysore, at Gudjelhutty in Coimbatore, at the Tapoor Ghat in Salem, at Chennimully in Coimbatore, and in Cuttack. At Namaul and at Viralimodes, on the north bank of the Cauvery, in the Perinutty talook, Salem district, it occurs embedded in gneiss, and a greyish earth, resulting in part from the disintegration of that rock. It is found in this vicinity in great abundance, in a low hill near the village of Sholasigamany, Trichingode talook, Caranel, Anpore, Mallapollaye, and at various localities up the river Cavery, as far as Cocarambadi, where it is dug for by the Natives in the fields; and there are the remains of many ancient excavations still to be traced. The corundum was formerly sent as an article of traffic to Palghatcherry, and thence to the Western Coast and various other parts of India. It can still be procured at the rate of from fifteen to thirty measures the rupee, each measure weighing fifty-seven ounces, avoirdupois. The caste usually employed in collecting it is the Vittaver.

Ruby localities.—Fine rubies have, from time to time, been discovered in many of the corundum localities just enumerated, associated with this gem, particularly in the gneiss at Viralimodos and Sholasigamany. The natives inform me that it occurs also in the Trichingode talook and at Mallapollaye, but it is rare, comparatively speaking.

Garnet.—This gem, the red variety, is very generally diffused over India. Its geognostic position, the hypogene or metamorphic schists, more particularly near their line of junction with the plutonic rocks, or trap dykes; for instance, in the crystalline and metalliferous areas of Salem and Nellore, already described, whence the finest crystals are procured, and sold by the Native merchants at an insignificant price. Colophonite is not uncommon in these tracts, as also in Mysore, the Neilgherries, the Carnatic, and other provinces of Southern India. It usually occurs in the granite, associated with the hypogene schists. That beautiful variety of dodecahedral garnet, called cinnamon-stone or essonite, has been discovered in the Neilgherries in the hypogene hornblende rock, near the seven Cairns Hill, by Dr. Benza, where their number is such, he informs us, that entire portions of the rock are formed almost exclusively of them. The essonite and hornblende are in large separate crystals, imbedded in a paste of compact felspar and hornblende; the former is very liable to disintegrate, leaving, in falling out, small cavities in the rock. *Green garnet* is of rare occurrence: the only locality where I discovered this gem was in the Salem district at Sankerydroog, lat. 11°29' N., long. 77° 58' E., associated with other green crystals in quartz veins, penetrating hornblende schist. The latter is associated with gneiss, garnet rock, actinolitic schist, and altered limestone, thrown into disorder by the intrusion of a porphyritic granite. The green garnet is not found in considerable quantities. A mine of precious garnet occurs at Gharilpit, about eight miles south of Palumshah, in the Hyderabad country, in the detritus of a granitic rock, penetrated by trap dykes, and composed of mica, garnets, kyanite, quartz, and felspar. Dr. Voysey, who gives a description of this mine *July* 18, states that the precious garnets are found at the depth of eight or ten feet in the alluvium at the foot of the rock. The surface of the rock and soil were strewed with garnets in great profusion, but these were generally of a very coarse kind. The garnets when collected are gently pounded, and the bad ones broken: those which survive the blows are reckoned of good quality. It occurs in great abundance near the Munzerabad-ghat, in Mysore.

Corundum.—Bournon considered indianite and fibrolite to be the matrix of corundum in Southern India, and Phillips states, on what authority is not mentioned, that its gangue in the Carnatic is a coarse grained white marble. I have always found it, both in Mysore and Salem, in talc, mica, or hornblende schist, associated with iron ore, asbestus, and sometimes indianite and fibrolite. It occurs imbedded in the rock in grains and crystals. Viralimodos and Sholasigamany are its principal localities in the valley of the Cauvery; Golashully and Kulkairy in Mysore, where it also occurs at Mundium near Seringapatam, Tippaty, Beygoor, Bannercota, Baugoopilly, and other places. It is also said to be found in the hypogene schists of Nellore and Guntoor. The spinel ruby (dodecahedral corundum) and sapphire (the corindon hyalin of Haüy) are occasionally found with the common corundum in the Salem district, and in the valley of the Cauvery. Emery, or granular corundum, is found at Bombardipadu, about twenty four miles northerly from Tripaty in North Arcot, in hornblende rock, in pieces varying from the size of a pea to that of a hen's egg, or even larger. Common corundum is also found where the Godavery escapes through the eastern ghauts, east of Papconda, from the Nizam's territories to the plains of Rajahmundry and the sea. Beryl occurs at Paddioor in Coimbatore; and, according to the Natives, at Vaniambaddi, at the north base of the Neilgherries.

Fibrolite occurs but rarely with indianite and corundum, as has been before alluded to, in speaking of the last two minerals. Kyanite I found associated with adularia, asbestiform tremolite, and magnetic iron ore, at Adipuram, in the Nellore district, in gneiss: it occurs in the same rock near Gharibpett, in the Nizam's territories; also in Mysore, and in the maritime districts of the Godavery and Kistna with tremolite, pearl spar, bitter spar, almandine and staurolite.—*Editor's report on Govt. Museum for* 1856.

(2898) CORVIDÆ, Crows, a family of Birds belonging to the division *Conirostres*. The bill is strong, slightly cultrirostral, or more or less compressed; the gape or commissure straight. The nostrils are covered with stiff, bristle-like feathers directed forwards.—*Eng. Cyc. page* 152. Every large black Crow, in whatever region, is sure to be denominated "the Raven:" and hence the Raven (*Corvus corax*) came to be considered as a bird of almost universal distribution. "It is one of those birds," writes Mr. Mudie (in his 'Feathered Tribes of the British Islands'), "which inhabit almost all latitudes, and have there plumage unchanged by varieties of season or of climate. The genus *Corvus* has no representative in all South America, nor in New Zealand and the numerous archipelagos of the Pacific, and there is one species only in Australia. Levaillant's Raven of South Africa, described by him as identical with that of Europe, has been sought in vain by subsequent observers in that region. The true Raven is pre-eminently a bird of the coldest climates: though a few occur so far southward as in the Barbary States, in America so low as in the Carolinas, and in India proper within the Punjab only. "The Raven," remarks Sir John Ross, "is one of the few birds that are capable of braving the severity of an arctic winter." But the finest account of this bird is by Von Wrangell, in his most impressive description of the fearful cold of a Northern Siberian winter; when—"even the Rein Deer seeks the forests to protect himself from its intensity: in the *tundras* [equivalent to the 'barren-grounds' of Arctic America], where there is no shelter to be found, the whole herd crowd together as closely as possible to gain a little warmth from each other, and may be seen standing in this way, quite motionless. Only the dark bird of winter, the Raven still cleaves the icy air with slow and heavy wing, leaving behind him a long line of thin vapour, marking the track of his solitary flight." The true Rook (*Corvus frugilegus*) is known to inhabit or visit the Peshawur valley, Afghanistan, Kashmir (the Rook of China and Japan being considered a distinct species, *C. pastinator* of Gould;) and the Jackdaw (*C. monedula*) accompanies it in those countries, while the true northern Raven is met with not only there, but also over a great portion of the Punjab. In other parts of India the comparatively small *C. culminatus* is popularly known to Europeans as "the Raven:" but the northern Raven would make a meal of one and not feel much the worse for it!

Fregilus.—Bill longer than the head, slender, entire, arched, pointed. *Fregilus Enca*, of Horsfield, from Java, for instance.—*Eng. Cyc. p.* 163.

(2899) CORYDALIS CASHMERIANA. Of this nothing is known.

(2900) CORYDALIS, Fumariaceæ. *C. Glauca*. These plants are of a rapid growth and well adapted for covering trellis work.

(2901) CORYDALIS GOVANIANA, Wall., (*Vern.* Bhootkes) is common in the Choor mountains, above 8000 feet of elevation, where it is regarded as a charm against evil spirits. The roots sent by Dr. Falconer, were long, fibrous, tough, and exceedingly bitter; dark brown externally, yellow within.—*O'Shaughnessy, page* 185.

(2902) CORYLUS, a genus of Plants after which the natural order *Corylaceæ* receives its name. The *C. lacera* and *C. ferox* are two species found in the Himalaya Mountains. Of these, the former, gathered in Kumaon, is hardly different from *C. colurna*; the other, from Mount Sheopore, has narrow taper-pointed leaves, and excessively hard nuts inclosed in a husk, with divaricating narrow spiny divisions.—*Engl. Cyc. p.* 166.

(2903) CORYLUS AVELLANA, (Hazel). Abundant in the Himalayas, nuts called *Bindick* and *Finduck* in bazars. Fruits (nuts) grouped in clusters together. Inodorous, taste sweet and agreeable. The almond becomes rancid very quickly. By expression the kernel yields a very agreeable oil, nearly in the proportion of half its weight. The wood of the hazel was the material of the divining rods of the magicians and snake enchanters, who even in modern times have had their believers in Europe.—*O'Shaughnessy, page* 609.

(2904) CORYPHA, a genus of Plants belonging to the natural order *Palmaceæ*. It has gigantic fan shaped leaves, flowers with a 3-toothed calyx, 3 petals, 6 stamens, and a 3-celled ovary. The fruit is composed of round 1-seeded berries.—*Engl. Cyc. page* 167. Among other Palms which are valued for different products and employed to supply the place of cordage plants, we may instance the species of this genus Corypha. Of these, *C. Gebanga* has its young leaves plaited into baskets and bags, affording much employment to the people in Java. The leaves are also employed for thatching, and for making broad-brimmed hats, So, *C. Taliera*, the *Tara* of Bengal and the *Talipat* of the Peninsula, is much employed for making leaf hats and leaf umbrellas. The leaves, moreover, when smoothed, are much used for writing on, and also for tying the rafters of their houses, as they are strong and durable. Thus, also, *C. umbraculi-*

fera, the *Codda-panna* of Madras and the *Talipat* of Ceylon, and very like the former, is common in Ceylon, and found also on the Malabar coast. Of this the leaf, being dried, is very strong and limber—and, according to Knox, "most wonderfully made for men's convenience to carry along with them; for though this leaf be thus broad enough to cover fifteen or twenty men when it is open, yet it will fold close like a lady's fan, and then it is no bigger than a man's arm; it is wonderfully light." "This tree is within, a pith only; they beat it in mortars to flour, and bake cakes of it, which taste much like to white bread; it serves them instead of corn before their harvest is ripe." (Knox's 'Ceylon.')—*Royle Fib. Pl.* The Burmese books are all made of the leaf of a species of Corypha.—*Seeman.*

(2905) CORYPHA ELATA, according to Mr. Mason, grows in the Tenasserim Provinces.

(2906) CORYPHA GEBANGA is one of the most useful of all the palms of Eastern Asia. Its pith furnishes a sort of sago; its leaves are plaited into bags and baskets and used for thatch and broad-brimmed hats; fishing-nets and linen shirts are woven from its fibres, and ropes from its twisted leaf-stalks; the root is both emollient and slightly astringent; sliced, it is used in slight diarrhæas, and Waitz says that it is a most valuable remedy for the periodical diarrhæas which in the East Indies attack Europeans.—*Eng. Cyc. page* 167.

(2907) CORYPHA TALLIERA, the *Tara* of Bengal, and *Talipat* of the peninsula of India, is an elegant stately species inhabiting Bengal. Its trunk is about 30 feet high, and as nearly as possible of equal thickness throughout. The leaves are in about 80 divisions, each 6 feet long by 4 inches broad, radiating from the point of a leaf-stalk from 5 to 10 feet long, and covered with strong spines at its edge. Roxburgh describes the spadix as decompound, issuing in the month of February from the apex of the tree and centre of the leaves, forming an immense diffuse ovate panicle of about 20 or more feet in height. The fruit is the size of a crab-apple, wrinkled, dark-olive, or greenish-yellow. The leaves are used by the natives of India to write upon with their steel styles, and for other purposes.—*Eng. Cyc. page* 167. In Tenasserim, it is known as the book palm and specimens of this palm, the leaves of which are commonly used to write on instead of paper, are not infrequent in the neighbourhood of religious edifices.—*Mason.* The leaves of Corypha talliera are said to be greatly employed in the Tenasserim Provinces,

(2908) CORYPHA UMBRACULIFERA, Lin. KODA PANEI.

Kodda panei marm, TAM.

The Tala, or Talipat Palm, is a native of Ceylon, and similar in appearance; but its leaves are not so round as those of the Talliera, the divisions in the centre being shorter than those at the sides. The trunk grows 60 or 70 feet high; the leaves are 14 feet broad and 18 feet long, exclusive of the stalk, and they form a head about 40 feet in diameter. Fans of enormous size are manufactured from this plant in Ceylon; the boll of this palm is wholly pith which furnishes a sort of flour from which bread is made; the leaves make excellent thatch, and are also used for writing on, like those of the Talliera.—*Engl. Cyc. page* 167. Griffith met with trees in flower at Mergui, which he thought belonged to this species, but "not having access to a complete copy of Martius' Palms," he could not speak with certainty. For the same reason, other trees that Mr. Mason saw in Tavoy, must be stated as probably talipat palms. The dark coloured roundish seeds of these trees are used as beads by the Taders, (religious fanatics of the sect of Vishnoo) which people the Telingas call Dasaries. —*Ains. Mat. Med. page* 143.

(2909) CORYPHÆNA, (Linnæus), a genus of fishes belonging to the section Acanthopterygii and family *Scomberidæ*. The group of fishes formerly included under the head Coryphæna is now sub-divided, and the sub divisions may be either termed subgenera of the genus Coryphæna, or the group may be looked upon as a sub-family and the sub divisions as genera.—*Engl. Cyc. page* 168.

(2910) CORYSTES, a genus of brachyurous or short tailed Crustacea.—*Engl. Cyc. page* 169.

(2911) COSMEA BIPINNATA. *Compositæ.* The species of this genus are mostly annuals and ornamental flowers, colours purple, white and yellow, the roots are tuberous, and may be cultivated by dividing the same or by seed.—*Riddell.*

(2912) COSMETIC BARK. *Murraya paniculata.* The fragrant bark of a tree which is indigenous in Burmah above Rangoon, is more universally used for a cosmetic than sandal wood. —*Mason.* A single specimen has been shown in Maulmain, which is a very ornamental fragrant flowering shrub of the citron tribe.—*Mason.*

(2913) COSMETIC TUBERCLES. *Toddalia aculeata* and *Toddalia floribunda.* An inferior cosmetic wood is seen in market, which is the tubercle of some plant. The Burmese appear, from their name, to regard them as produced by a species of erythrina, for they call them "erythrina thorns" but Mr. Mason knows the plant to be a creeper, and suspects that it is of the above genus.—*Mason.*

(2914) COSMETIC WOOD OF MERGUI. *Xanthoxylaceæ?* There is a fragrant cosmetic wood sold in the bazar, which is said to come from Mergui, but Mr. Mason never saw the tree.—*Mason.*

(2915) COSSYAH or KHASSIA COUNTRY. The Cossyah Country on the N. E. frontier of

India has iron of great purity, smelted at Pundua; Cassia Lignea is one of its principal articles of export; and a variety of parti-coloured cloths, generally known by the name of Sylhet cloths. Some of them are dyed of rich colours, and being of a strong durable texture, are well adapted for table covers, to which purpose they are usually applied in the Eastern part of Bengal.

(2916) COSTUS OR PUTCHUK. The substance called costus was highly prized by the ancients, and specimens may be met with at a few of the London drug-houses. It has been shown by Dr. Falconer to be the produce of a genus of the thistle tribe, to which he has given the name of *Aucklandia*. Dr. Falconer found it growing in great abundance all round the elevated summits of Cashmere. From the plants with which it was associated, and the circumstances under which the Koot grows, being one of the Compositæ,or Thistle tribe,with feathered seed,of which, when once established, the dissemination becomes easy; Dr. F. has no hesitation in thinking that it could be produced to an unlimited extent, of the best quality, in the Himalayas at elevations of from seven thousand five hundred to nine thousand feet above the sea, and that the Choor mountain alone might be brought in a few years to produce thousands of maunds of it. Preparatory to diffusing the Koot, or Costus, he has introduced it into the Mussooree nursery.—*Royle Pro. Res.* The root of *A. Costus* is supposed to be the *Costus Arabicus*, on the following grounds:—It corresponds with the descriptions given by the ancient authors, and is used at the present day for the same purposes in China, as costus was formerly applied to by the Greeks. The coincidence of the names—in Cashmere the root is called koot, and the Arabic synonym is said to be *koost*. It grows in immense abundance on the mountains which surround Cashmere. It is a gregarious herb, about six or seven feet high, with a perennial thick branched root, with an annual round smooth stem, large leaves and dark purple flowers. The roots are dug up in the months of September and October, when the plant begins to be torpid; they are chopped up into pieces, from two to six inches long, and are exported without further preparation. The quantity collected, according to Dr. Falconer, is very large, amounting to about two million pounds per annum. The cost of its collection and transport to a mercantile depot in Cashmere, is about 2s. 4d. the cwt. The commodity is laden on bullocks and exported to the Punjaub, whence the larger portion goes down to Bombay, where it is shipped for the Red Sea, the Persian Gulf, and China; a portion of it finds its way across the Sutlej and Jumna into Hindostan Proper, whence it is taken to Calcutta, and bought up there with avidity under the name of putchuk. The value is enhanced at Jugadree, on the Jumna, to about 16s. 9d. or 23s. 4d. per cwt. In the Chinese ports it fetches nearly double that price per cwt. The Chinese burn the roots as an incense in the temples of their gods and regard it as aphrodisiac. The import into Canton

In 1848 were 414 piculs and
„ 1850 „ 854 „ Valued at 5,150 dollars.

In Cashmere it is chiefly used for the protection of bales of shawls from insects. The Exports from Calcutta, were

In 1841 1842 ... 12,847
„ 1847 1848 ... 2,050½
„ 1848 1849 ... } 2,110½ worth about £1,500 annually.—*Sim.*

It will thus be seen that this root forms a rather important export from Calcutta. It is brought from Lahore, where it is called *koot*, and is sold in the Bengal bazars under the name of kooth, kust, and koshta; one kind is called *koosht tulkh*, or the bitter; another, *koosht shereen*, the sweet or mild; the latter is of light yellow colour and pleasant smell. Mr. Royle supposes it to be identical with the Indian orris root, but this is called *beg banopsha*, and is imported from the Red Sea. It appears to us to be in every respect identical with the true orris root. According to Dr O'Shaughnessy writing in 1842, *Putchuk* is of unknown origin; though usually referred to *Costus arabicus* or *speciosus*; the roots of the latter are quite insipid and inodorous. The putchuk is chiefly exported to China, where it is used as incense. Mr. Royle inclines to the opinion that it is in reality the produce of an umbelliferous plant; specimens have been seen by Mr. Beckett of Allyghur having hollow stems.—(*Royle p.* 360.)—*O'Shaughnessy, page* 652.

(2917) COSTUS ARGYROPHYLLUS. An indigenous species of the spirical costus is very abundant in Tenasserim, but not described in the books to which I can refer.—*Mason.*

(2918) COSTUS. Dr. Wight has given figures of Costus page 15, Vol. VI. 2015, *Nepaulensis*, 3014, speciosus. 2014.

(2919) COTTIE KALUNG TAM.—APONOGETON MONOSTACHYON. THUNB. It is commonly found growing in the beds of tanks. Thunberg in his "Travels," tells us, that this root is eaten in Caffraria, as a great delicacy; It does not appear to be less relished by the natives of India.—*Ainslie, page* 248.

(2920) COTTON,

Kutun, ARAB.	Kapas, MAL.
Bomuld, DAN.	Pumba, PER.

Ruhie, HIND.	Algodon, SP.
Bambagia, Cotone, IT.	Bomull, SW.
Gossypium, Bombax, LAT.	*Faulkner.*

The hairs attached to the seeds of *Gossypium herbaceum* and other species of the genus Gossy-

pium or Cotton. Cotton has been characteristic of India from the earliest times. The first distinct notice of it is in the Book of Esther, i. v. 6, where its Sanscrit name *Karpas* is translated *green* in the English Bible. Herodotus and Ctesias notice it, but it was not till the invasion of India by Alexander, that the Greeks were acquainted with the plant, as may be seen in Theophrastus and also in Pliny. Europe is now supplied chiefly from America, where two distinct species are indigenous; *G. Barbadense;* yielding the Cotton from the United States, and *G. peruvianum* or *acuminatum*, that which is produced in South America. India also has two distinct species, *G. herbaceum*, or the common Cotton of India, which has spread to the south of Europe. and *G. arboreum*, or Tree Cotton, which yields little if any of the cotton of commerce (very distinct from the species of Bombax often called Cotton-tree and Silk Cotton-tree). The species consist of large or small shrubs, and one forms a tree. All have alternate leaves, which are more or less palmate or lobed, and usually covered, as well as the young branches, with little black dots, and the nerves below have one or more glands. The calyx is double, the exterior (involucel) is larger than the interior, divided into three large leaflets, cordate at the base, entire, toothed, or deeply cut along the margin. The interior or true calyx is one-leafed, cup-shaped, and with an obtusely quinquifid margin. The flowers are large and showy, more or less yellow or red, consisting of five petals united at their base, subcordate, flat and spreading. Stamens numerous, filaments united below and adhering to the petals, free above, with small kidney-shaped anthers. Ovary superior, oval, roundish or pointed, terminated by a style, which passes through the cylinder formed by the stamens, marked with three or five furrows towards its apex, and dividing into three, sometimes into five stigmas. The capsule is roundish, oval or pointed, three to five celled, and three to five valved at the apex, with loculicidal dehiscence. Each cell contains from 3 to 7 ovoid seeds, from the seed-coats of which arises the filamentous substance, which by its twisting envelopes the seeds. Along with this Cotton there is often a shorter covering, called *fuzz* by planters. Cotton wool is formed of tubular hairs, which in drying become flattened, and are transparent, without joints, and twisted like a corkscrew. Under water, they appear like distinct, flat, narrow ribands, with occasionally a transverse line, which indicates the end of cells. This twisted nature of the Cotton fibre is probably the reason why Cotton cloth is not so well fitted as linen for surgical dressings. But being a worse conductor of heat than linen, it is well suited for inner clothing, where the object is to preserve uniformity of temperature, as it will retain heat, and prevent the body being so readily affected by external heat or cold. At the same time that it condenses less freely than linen the vapour of perspiration, but absorbs it readily when it has been condensed into the form of sweat. For these reasons probably, thick calico shirts, &c. have been introduced into the army for the use of soldiers.—*Royle, page* 289. The cotton plant or shrub (*Gossipium herbaceum*), of which there are many varieties, is indigenous in the tropical regions of Asia, Africa, and America. It flourishes also in the southern provinces of the United States; and, although an exotic there, has been cultivated with such success, that its produce is at the present time an all-important article of commerce. Cotton may be described in its unmanufactured state as a sort of vegetable wool, which bears value according to its color, length, strength, and fineness of fibre. Pure whiteness is generally held to denote a secondary quality; whilst a yellowish tinge, provided it be not the result of casual exposure to damp, or the natural effect of an unfavourable season, is indicative of superior fineness. Many varieties of raw cotton figure in the market, each sort being usually distinguished by the name of the locality where it is produced; but the main distinction recognised is that between the long and short *stapled* qualities; though of these, again, there are different degrees of excellence. The "sea-island" cotton of Georgia (so named from its being raised on certain narrow sandy islets lying along the coast of that province) is esteemed the best of the long-stapled kind; and the "upland" produce of the same state excels amongst the short-stapled classes. The indigenous Asiatic cotton is exclusively of the latter species. The manufacture of cotton—a business in Europe of growth so recent as the end of the sixteenth or beginning of the seventeenth century—has been carried on in India from very remote antiquity. As noticed above Herodotus and, at a latter period, Arrian, speak of certain wild trees in that country, producing a kind of wool superior to that of the sheep in their day, and state that a cloth woven from this substance was in universal wear amongst the inhabitants in their day. The natives had, indeed, attained such a perfection in the arts of spinning and weaving, that the lightness and delicacy of their finest cloths emulated the gossamer's web, and seemed to set competition at defiance. Yet neither the extreme cheapness of his labor, nor his acknowledged manual skill, has enabled the Indian artisan to withstand the triumphs of mechanical genius. And the striped and figured muslins of Dacca, so long celebrated throughout the world for the beauty and delicacy of their fabric, are now almost entirely displaced by the productions of Manchester and Paisley. But cotton is nevertheless, even now, one of the leading features of Indian agriculture. It forms part of an established

course in most village lands throughout the plain country; and except upon swampy, desert, or absolutely sterile ground, there is no situation in which it cannot readily be grown. Thus within the vast confines of the English Empire in the East, no particular limits can be assigned as constituting the "home" of the cotton shrub. In the lower provinces of Bengal, where the cultivation of the plant is almost entirely limited to the requirements of the local population, there are five districts—viz., Chittagong, Cuttack, Maunbhoom, Loharnuggur, and Assam—in each of which upwards of 10,000 acres of soil are so appropriated. And in some of these, as well as in several other districts where the present acreage is considerably less, it is known that the cultivation might be widely extended. In the North Western Provinces, a late return informs us that cotton is, more or less, grown in every pergunnah or district—from Kumaon, with 260 acres, to Banda, which exhibits 230,557 acres under cultivation. The eastern shores of the Bay of Bengal are no less favorable to the production of cotton. It is found, too, in the more arid climates of Scinde and the Punjab; whilst it grows luxuriantly on the sea-board of Cutch, and in the fertile peninsula of Guzerat. But the grand cotton field of India lies partly within the dominions of the Nizam, and partly in the province of Nagpore. The extent of cotton cultivation throughout this vast tract cannot be estimated with any near approach to accuracy. But this region is, beyond doubt, the part of India from which Great Britain might, in case of need, draw the raw material in inexhaustible abundance. In addition to the immense resources which here only await development, the Bombay Presidency (including some native states that lie within its limits,) exhibits a grand total of 2,890,279 acres, now or lately under cotton cultivation. Exclusively, in fine, of what may be raised in the newly acquired territories of Burmah and Pegue, it is on official record that, throughout the length and breadth of British India, the aggregate extent of cotton growth was very recently no less than 5,147,223 acres; and this already vast area is universally allowed to be capable of being almost indefinitely enlarged. In the face, then, of India's admitted ability to furnish not only Great Britain, but, were it requisite, the whole world besides, with an ample and unfailing supply of the raw material—let us see how the facts of the case stand in practice. The Board of Trade returns show that the total imports into Great Britain of Indian cotton, during five years (from 1849-50 to 1853-54,) were as follows, viz;—

	lbs.
From Bengal, ...	10,573,653
" Madras, ...	43,093,473
" Bombay,...	598,218,675
Total from India...	652,785,801
From other countries, ...	3,368,282,031
Total imported by Great Britain, ...	4,021,067,832

From which statement it will be seen that India contributes no more than about one-sixth, or nearly sixteen per cent., of the whole amount of cotton consumed by Great Britain. Last year, indeed, an increased demand in the home market raised the per-centage for 1856 to 26⅓: but half a century since, in 1806, the ratio of Indian imports was as high as forty per cent. During the period that has intervened, the supply of cotton from the United States of America has increased fourteenfold, whilst that furnished to us from India has augmented only ninefold. To the Manchester Commercial Association and Chamber of Commerce, we are mainly indebted for the efforts which have from time to time been made by the East India Company, to improve the cotton staple by introducing a better system of cultivation, and to create additional facilities for transporting and shipping the raw material. Yet up to the present time comparatively little has been done in either respect. But something at all events, has been proved; since, at the meeting already referred to, Mr. Bazley informed his auditors that, in August last, he had seen some very beautiful specimens of cotton from India, which were worth 15d. per pound. These specimens were, no doubt, raised from foreign seed. The indigenous plant of India is an annual, and succeeds best in the rich black soil that characterises various districts. The American plant, though in reality perennial, is practically an annual in India; for in that country neither native nor foreign cotton is cultivated on the same ground more than one year in three, its properties being found to exhaust the productive powers of the soil. The American cotton grows well on the black soil, but thrives still better on the light red lands. Each species possesses advantages peculiar to itself. The Indian variety is capable of being manufactured into fabrics of extraordinary durability and wonderful fineness; its color, too, is superior, but the staple short. The American species, on the other hand, excels in length of staple; the plant yields more flowers, and each flower a larger pod, whilst the quantity of seed contained in the pod is smaller and more readily separated from the fibre. It is now close upon seventy years since the rulers of British India made a first attempt to extend cotton culti-

vation, to improve the staple, and to establish better methods of cleaning and packing the produce. Those who are at all acquainted with the Asiatic mode of conducting business, will be at no loss to imagine (should they never have witnessed it) the unsatisfactory manner in which the last-named important operations would, in all likelihood, be performed. The distribution of seed of a superior quality commenced so far back as the year 1788. Rewards were next instituted to stimulate exertion, and instruments both agricultural and mechanical, superior to those in use among the natives, have since been extensively introduced. In 1813, the services of an experienced American cultivator were obtained, and trans-Atlantic gins were at the same time first imported with a view to expedite the cleaning process. In 1818, again, some further activity was manifested; and in 1831, experimental farms were sanctioned in the Southern Mahratta country and in Guzerat. But these, after much expense had been incurred, were abolished, apparently as failures, by the local government, in 1836. Still, the Court of Directors expressed great anxiety "that no means should be left untried which might be likely to assist the desirable object of improving and extending the cotton cultivation on the Bombay side of India." The local government then proposed granting farms upon advantageous terms, and even making pecuniary advances to respectable parties who might be desirous of cultivating cotton, and to this suggestion the Directors partially acceded. But ere their qualified consent could reach Bombay, the authorities on the spot had already determined upon a far more extensive measure of encouragement—viz., the exemption from the land revenue, for five years, of all lands sown with cotton in the collectorates of Poona and Ahmednuggur. This scheme, however, was disapproved of by the supreme government of India, and eventually disallowed by the Court of Directors. Again, in 1839, it was resolved upon to obtain further practical information in the cotton-producing districts of the United States: and to engage on the spot the services of competent persons, who should proceed to India for the purpose of instructing the native growers in the best modes of culture and cleaning. This determination was shortly after carried out. Ten Americans of approved experience in the management of cotton plantations were despatched to India, their services being distributed as was deemed most advantageous among the different presidencies. Some experimental gardens were established at Rutnagherry on the western coast—a district (strange to say) in which the cultivation of cotton was not generally prevalent. Under such circumstances, we are not much surprised to learn that the experiment in question was abandoned after a short and unsatisfactory trial. At the same period, the government farms were again established in Broach, Dharwar, and Candeish. But in the first named district (where the culture of New Orleans cotton was more especially aimed at) no good results were achieved beyond the limits of the farm; and notwithstanding a lavish expenditure, no improvement was effected in the staple of the country. In 1846, the other farms were abolished, and at this time the contract system of cultivation was introduced both in Dharwar and in Candeish. Upon this plan, the native cultivator merely undertakes to grow a certain description of cotton, and the government, without any further interference, engages to receive the produce. The soil and climate of Candeish are described as well suited to the growth and culture of New Orleans, Egyptian, Bourbon, and other foreign varieties of cotton. The farms established by government in Coimbatoor, Tinnevelly, and other districts of the Madras presidency have been also discontinued; it being alleged that the object for which these establishments were formed has been fully attained in demonstrating that the soil and climate are capable of producing cotton suitable to the British market. The general results of American management under the Bombay Presidency, up to the year 1844, have been embodied in a report from Mr. W. R. Mercer, one of the cultivators engaged. Considering how little had been effected, and how large an expenditure incurred, Mr. Mercer's statements appear more favorable, upon the whole, than we should have anticipated. But before referring to these in detail, let us take occasion to enquire what opinions have been placed on record by other parties, whom long residence in India, knowledge of its people and their habits, and a tolerably intimate acquaintance with the subject under discussion, combine to designate as trustworthy witnesses and competent judges. It must be borne in mind that the introduction of improvements in India is a task of no small difficulty, and requires very delicate management. "The indigenous cotton of India is naturally inferior; and besides, the staple is ruined by bad cultivation, bad cleaning, bad packing, carelessness in transport, and wilful adulteration." Now, reverting to Mr. Mercer's report already mentioned, the American cultivators express their opinion of the article produced in anything but disparaging terms. Mr. Mercer and his colleagues aver that Indian cotton has long been known to possess two very remarkably good qualities. It "gills" or swells in bleaching, thereby yielding a more substantial fabric; it takes and retains color better than American cotton, and it would command a good market if sent in regular supply and of uniform cleanness. On the same authority, we learn that the natives of large cotton tracts in India already employ a mode of cultivating the plant in principle nearly the same as the American, but better suited in some re-

spects to local circumstances. Mr. Mercer's ultimate conclusions were, that it is erroneous to suppose that the cultivation of varieties of American cotton would be very beneficial to India; that the staple of Western India was as long, as strong, and equally as good as the new Orleans, and, in respect of the qualities above specified, more valuable. In fact, nothing was required but better cleaning to make the cotton of India equal, if not superior, to New Orleans. The latter portion of this flattering judgment was pronounced in December, 1846, and was not without its effect in the local markets. For when, in the following year, the Bombay government exposed for sale a quantity of Dharwar New Orleans seed cotton, and at the same time a lot of the best native Candeish (both cleaned, prepared, and saw-ginned for the English market by government servants) the native cotton was sold on the spot at fifteen to twenty per cent. higher than the Dharwar New Orleans seed. But on the arrival of the consignment at Manchester, the previous judgment was something more than reversed—the Candeish best native selling there for 3½d., the Dharwar New Orleans for 6¼d. per lb. The verdict of Manchester was necessarily decisive; and subsequently to this occurrence, the Bombay price-lists for several years show, that the Dharwar American seed cotton has realised an average of ten to twelve per cent. higher than the best native produce of Western India; and about twenty-five per cent more than any other cotton grown in the Southern Mahratta country, or in the neighbouring districts of Mysore and the Nizam's dominions. The entire Southern Mahratta territory, embracing the two collectorates of Belgaum and Dharwar and a few independent states, was formerly entrusted to the superintendence of a single civil functionary under the Presidency of Bombay. But the charge being justly deemed too onerous for an individual, the existing division was made within the last twenty years. Reference to the map of India will show that Belgaum is by about one-third the larger of the two collectorates. But their climate is one and the same—one dialect prevails throughout both; the people and country are, in short, identical. Yet of these contiguous, and as we may say, twin districts, there are printed returns which inform us that the area of indigenous cotton cultivation is much less considerable in the larger province of Belgaum; whilst, as regards the exotic species, Dharwar has been lately represented as exhibiting 63,000 acres under cultivation, against only 1,300 or 1,400 in Belgaum. Upon these premises it is alleged that, although the American cotton may have succeeded in Dharwar—even to the extent of needing no further external encouragement or assistance—yet it has failed everywhere else. Now it may be true that no greater progress has been made in Belgaum than in other parts of the same presidency; but who shall venture to affirm that what has been effected in Dharwar cannot be equally effected in Belgaum, under precisely similar circumstances? The successful agent in the Dharwar experiments was a gentleman whose name is well known in connexion with the subject under discussion—Mr. A. N. Shaw, late of the Bombay Civil Service; and it is a mere accident that Belgaum was not the scene of his exertions, instead of Dharwar. Mr. Shaw, being at the time collector and political chief at the former station, was transferred to the latter post in 1842, at the very period when he was about to commence his subsequent operations. The success of the Dharwar experiments was not immediate. Mr Shaw had his failures and disappointments to encounter as others had; but he met both manfully, and his unflinching perseverance at last commanded favorable results. Thus the failures in Surat, Broach, Candeish, and other localities—classed, as they have been, together with Belgaum—may be said to prove nothing at all, in the absence of some distinct and special grounds assignable as the cause of failure in Belgaum. It may readily be conceded, that in the instances of Surat, Broach, and some other parts of the country, slightly varying modes of treatment might be desirable, and earlier or later planting, or even the introduction of a different class of cotton, would possibly prove advantageous. The long extent of sea-coast about Surat and Broach, embracing many hundred miles, would seem particularly well adapted to the culture of the more valuable staples—such as Sea-island, Pernambuco, Egyptian, and Bourbon. The scene of Mr. Shaw's labors was laid in a district where the soil and climate have long since been recognised as eminently suitable to the growth of cotton. But that gentleman's testimony and general experience are abundantly confirmed by evidence from less favored quarters. A distinguished member of the Bengal Civil Service, located in the North Western Provinces, has within the last few months made public the results of many years' close attention to the practice of cotton cultivation. This valuable witness has always been of opinion that the government experiments, the event of which he watched with great interest, had the elements of failure inseparably connected with them; whilst, by repeated experiments upon his own grounds, he had become fully satisfied of India's capacity to supply the home-market with any amount, even of exotic cotton. The Bengal civilian justly observes that, in order to improve the Indian staple by the introduction of exotic varieties, we must demonstrate that a given area can be made to produce a certain quantity, which will sell higher than the produce of the same area grown from indigenous seed. He himself during ten years cultivated Mexican cotton, and the acclimated produce was pronounced excellent in

Lancashire. The average yield per acre was from 200 to 250 lbs. of *clean* cotton. Here is enough to show what can be done, even in Upper India. But the assistance of irrigation is sometimes necessary; and the government experiments were made on land not irrigated, their success being thus dependent upon the periodical rains. These in Bengal and the North Western Provinces do not ordinarily set in before the middle or latter end of June; whereas foreign cotton for the English market should be sown by the middle of March. The Ganges canal is capable of irrigating and trebling the productive powers of millions of acres. Our Bengal civilian would establish experimental cultivation at various points on the canal, under the supervision of its officers, and afterwards distribute seed; taking care that the villagers should sow at the proper season, and be careful about picking the crop *clean*. Encouragement might be offered to the cultivators in remission of land or water tax, or by buying up the produce at the highest rates affordable. Desultory attempts have already been made, but a systematised introduction of acclimated seed is required, together with strict supervision both of culture and gathering. It were needless to multiply evidence of the foregoing description. But whether we accept the testimony of the American planters, or adopt the conclusions of Mr. Shaw and the Bengal civilian, practical experience may be safely represented as establishing the fact that India *can* produce excellent cotton, and her capability of producing the same in any quantity depends only upon an increase of the necessary facilities. The objections as to cleansing, packing, and adulteration, whether accidental or wilful, bear reference to matters of detail, which we cannot afford to discuss at present. But there can surely be no insuperable obstacle to the redress of these imperfections and abuses. Under a better system, it is to be hoped that diligence and honesty will prove more remunerative than indolence and roguery are at present. An effective remedy has moreover been already suggested in the proposed establishment of direct relations between the cultivator and the manufacturer. It has been said that "India cannot compete with the United States." Perhaps not, as regards the very finest descriptions of cotton, though even upon this point there may be room for question. But as regards such sorts as would rank in the home-market under the denominations of "fair" and "good fair," it is already on record that India is able to compete with the States most successfully. Dr. Wight of the Madras Medical Service, who for eleven years superintended the Coimbatore experiments, informs the Committee of the House of Commons [Indian Territories, Fourth Report, Quest. 5,952, et. seq.] that Coimbatore cotton selling in Liverpool at 4d. per lb., would "barely remunerate" the grower. But prices vary with the fluctuations of American cotton; and "ours," says Dr. Wight, "has always borne nearly the same prices in Liverpool as American-grown cotton, under the same denomination, bore there." Thus the Coimbatore produce was generally ranked as "fair" and "good fair," and on the very day (6th June, 1853) when the Doctor gave his evidence, cotton under that denomination was fetching in Liverpool from 5d. to 5½d. per lb.—a price that would leave a very large profit. If such, then, were the result, when there was a weary transit of nine or ten days' duration, over bad and broken roads, to be accomplished ere the Coimbatore produce reached the port of Cochin—still more favorable to India will be the terms of competition when a railway unites the cotton-field and port. American-grown cotton is already selling at a *minimum* price—the Indian by no means necessarily so. In India, countless acres await the fuller development of cotton growth; but America is by no means possessed of the same indefinite power of extending cultivation upon anything like advantageous terms. The American crop occasionally is deficient: this may be an accident, but should still be regarded as a warning. It has also become evident that the demand for cotton wool is increasing beyond the amount that America will eventually be able to supply. Such a contingency had, indeed, been foreseen, inasmuch as the most able men engaged in the cotton trade had for years predicted its occurrence at no very distant period. Yet little has as yet been done to counteract the impending evil. The late Mr. Mackay's mission to India was a step in the right direction, and now or never is the time to reap the benefit of that lamented gentleman's advance and experience. No man better knew the appalling embarrassments which would accrue to England from the stoppage of even one year's supply of cotton; no man better knew that the extension and improvement of cotton in India is no chimera, and that the time may come when we shall find therein our safety.—*Dublin University Magazine, June* 1857. Mr. Bonynge, an American gentleman long resident in India, is of opinion that America has reached her utmost limit of producing cotton, and India must be depended on in future. He states that in America there has been a falling off in progressive increase of 54$\frac{10}{13}$ per cent., —but probably in the next ten years there will be no increase over the last ten. So it may be said, he adds, that the production of cotton in America has not increased materially for twelve years—there has been only an increase of 160,000 bales yearly, for the last six years, over the former six. Since the year 1839, the cotton crop in America is comparatively stationary in quantity; and it is seen that the cotton crop realized more in dollars for five years—from 1835 to 1840—than it has in the two following periods,

that is from 1840 to 1845, and from 1845 to 1850. He concludes, that this all-important staple—cotton—admits of no further increase for the employment of additional hands. And though cotton has done wonders for America; after a time, every thing gets old, and the Cotton States themselves complain that the land yields them nearly one-third less produce, and it sells for one-third less price. He is of opinion that it is not the want of suitable soil, climate, and cheap labor, that has left the cotton trade so largely in the hands of America. The cultivation in America, he considers, is in its senile years; while in other countries it is in its infancy, that is, in some, and in others in their lately renewed efforts; and they are even now formidable rivals, and America will have to struggle hard. But as far as the East Indies are concerned, it would not be the least surprising if that country monopolized altogether the cotton markets in a few years hence. That she can do so there is no doubt; that she has not done so under the half-dozen planters whom the East India Company have taken out there from Georgia, is no evidence to the contrary. The cause of the failure is one to be accounted for; the planting in the East is below 20 degrees of N. latitude. All Southern Americans know that it will not even do well low down in Florida, and that the cultivation is northwards of the 27 deg. to 36 deg. N. latitude. Probably India produces twice the quantity that America does. There is no over production for the world. The world would find people to wear twice the quantities of cotton clothing, but the lowness of prices must be tempting to the world for them to do so. For instance, Americans consume 11½ lbs. per head; it has been calculated that the East Indians consume 20 lbs. per head; Great Britain only 4½ lbs. per head. There is room, if returns be correct, for an increase in the consumption to take place in Great Britain of 7 lbs. per head, or say, some 210,0 00,000 lbs. The East Indian cotton contains 25 per cent of waste and dirt, while the American contains only 12½ per cent. It is somewhat difficult to spin the Indian, from its often breaking, and requiring more turns of the spindle, from its shortness of fibre, than that of America. But the yarn made from a pound of East Indian cotton, which cost 3½ pence sterling will sell for 7 pence, while from the American, which cost 4½ pence the lb., the yarn sells for 7¾ pence only, making up somewhat of the difference in value of the yarn. *Bonynge's America, p.* 36. The capabilities of India to produce cotton is seen from the following evidence. Mr. Chapman, manager of the Great Peninsular Railway Company, stated to Mr. Bazley, "That cotton of good quality for English use is always to be had in Berar at about 1½ pence per lb., ranging of late years from 1¼ to 7¼ pence per lb. The quality of this cotton is such, that at a certain relative difference of price (averaging about 15 per cent. less for Indian than American), it can be used instead of American for more than 50 per cent. of our manufactures; that is, will afford material for all yarns under No. 20." (Royle on cotton in India.) Mr. Mercer and Mr. Finnie, American planters, state that an inferior and dirty cotton is the most profitable article to the native trader, and even to the European merchants; and Mr. Petrie, stated before the cotton committee, that "Cotton, which would be sold in England at 4½ pence per lb., and cotton that would only bring 3 pence, will sell in India within 3 to 4 per cent of the same value. The cultivators know this, and therefore they have no object in bestowing more care and labor." Mr. Read, Commissioner of Benares division, wrote 16th August, 1848: "In this division, the cultivation of cotton is little more than nominal, it is most commonly mixed up with other crops, it is nowhere carefully attended to; in many places it is an object of superstitious aversion, and often when the plant contrives to struggle to maturity, it is left, after being stripped of a portion of the bolls, enough to supply domestic purposes, to be devoured by cattle." Mr. Bruce, in a letter dated 15th March, 1848, says: "that if the associations and manufacturers who have been memorializing and soliciting the authorities in England, regarding the increase of cultivation of cotton in India, actually wish for it, and will guarantee that all which may be produced through his exertions in this country will be taken by them, and paid for here, and will sent out responsible agents to receive charge of the cotton, either here or at Calcutta, he will engage and undertake to produce for them as much real good marketable cotton as they may require, and not cost them, when landed in England, more than about 3½ pence per lb., which he thinks very moderate, considering that Indian cotton generally realizes from 4½ to 5½ pence per lb. in England. "The Doab, as well as Bundlecund, has always grown considerable quantities of cotton, and will be able to grow a better quality as soon as the Ganges Canal, that most magnificent of works for irrigation, is completed."—*Royle. Bonynge America, page* 38. "The cotton of Jaloun and Jahnsi (writes Mr. Bell) was formerly much celebrated. Koonch is now the great mart in that direction, and it is surrounded by the Jaloun Territory. Mr. Bell, after making careful enquiries, ascertained that the cotton of Baugchenee was that which then was in most in repute with the natives of those parts, who gave about 7½ per cent more for it than for the other best kinds. The district is on the south of the Chumbul, near Dholpore, and therefore probably very similar in soil and climate to that of Jaloun and Jhansi, which are not very far distant. Mr. Bell further thought that it might be landed at Liverpool

in a clean and desirable condition for about 3½ pence per lb. As these districts, as well as Bundlecund, lie to the westward of the Jumna, and have always been famous among the natives for their cotton, it is probably owing to some physical pecularities of soil, or of climate, that the cotton is produced of a better quality, for we cannot discover that it has the advantage of any more careful culture or cleaning."—*Royle.* Mr. Mercer, the American planter, says, "Dharwar is more like the Mississippi climate than any other he has met with in India. The elevation modifies the climate, which also feels the influence of both monsoons or rains, so that it never becomes extremely dry, and is never inundated with excessive rains." Mr. Mercer finds the seed returning to it soriginal Mexican character, instead of deteriorating as in other parts of India. Government farming with American cotton, have themselves adopted and are rapidly increasing it, as they find it yields a larger quantity per acre, and they get a better price, even from the native weavers." The culture of American cotton has been greatly increasing in quantity; from 600 acres the first year (1842) to 15,000 acres in 1845. Mr. Mercer thought that not less than 1,000,000 lbs., of American cotton would be produced. This crop has now been ginned, and 40,000 rupees (20,000 dollars) worth, at 66¼ Rupees per 784 lbs. (*i. e.* 33 dollars in round numbers) has been bought from the ryots (farmers), for transmission to this country." The further expense of this cotton amounted to 17½ rupees, (exchange value of a rupee is 1*s.* 10*d.* or say 45 cts.) Some of this cotton (100 bales) was sold at Bombay for 113 rupees a candy, and the 500 which were sent to Manchester for 6½ pence a pound, having cost 3¾ pence a pound.—*Bonynge America, pages* 16 *to* 40. It only remains to state the mode of improving the Indian staple, which seems to hold forth the surest promise of eventual success. There can, we think, be no doubt that the safest and wisest course open is to bestow all possible attention upon the culture of New Orleans, Mobile, Upland, or Mexican cotton: which (in India) are practically one and the same article, the denomination only varying according to the locality from whence imported. This is the sort of cotton for which there would always be an unlimited demand at Manchester; and the cultivation of this species, besides bringing us into direct competition with the cottons most largely grown in America, and most extensively used in our own manufactures, involves other advantages. For the proportion of its seed being considerably less than that of most other cotton, an equal area sown with New Orleans is more valuable than if sown with other exotic or indigenous (Indian) seed, in the following respects:—Firstly, It gives a larger yield. Secondly, It yields more wool in proportion. Thirdly, It commands a higher price in the market. Fourthly, It requires no peculiar mode of culture or treatment, other than is applicable to the indigenous species. When this class of cotton has gained a firm footing in India, it must rest entirely with the discretion of cultivators and dealers, whether they will attempt introducing the finer staples in particular localities. But the New Orleans seed must be relied upon as the most generally remunerative, and the most universally suitable to Indian soils and climates. Irrigation must not be forgotten. In the Southern Mahratta country, one cwt. of *clean* cotton per acre may be accounted a fair yield; but by means of irrigation, the Bengal civilian, whose experiences we have cited, obtained double that yield in the North Western Provinces.—*Dublin University Magazine, June* 1857. Few subjects have occupied so much of public attention of late years,—have been so frequently discussed in books, in newspapers, and in parliamentary debates, as that of the production of cotton within the territories of the East India Company. None will be disposed to question the great importance of the subject. Whether we regard cotton in its broadest aspect, as affording ample employment to vast numbers of persons in its growth, transport, and shipment; whether we look at it as furnishing food for gigantic manufacturing establishments in the parent country, scattering wealth and happiness in its path; or whether we view it as an article of social moment, ministering to the health and comfort of the entire human race; whether we consider it as a source of revenue, as a staple of trade and manufacture, or as a great help to civilisation and progress,—we cannot but feel that we have to deal with a most important subject. India was unquestionably the birth-place of cotton cultivation and cotton manufacture. It is mentioned in the institutes of *Menu*, a work composed eight centuries before the Christian era, with many details relative to its manufacture and uses; and although not named in the *Rig Veda*, of still higher antiquity, there is no doubt that in more than one place the thread alluded to was composed of cotton. Possessing, therefore, so much antiquity, we need not feel astonished that, until the last half century, the culture, trade, and manufacture of cotton in India should have occupied a most important position in the commercial annals of the world. That the production of cotton goods in India would still have stood forward pre-eminently as a branch of industry, had not the modern improvements of machinery in Europe snatched from it all its ancient prestige, there can be but little doubt; although, as regards the cultivation of the raw material, other causes have been at work to spread it elsewhere, to an extent unprecedented in the history of the world's industry. It was a remarkable coincidence that at the precise time when Arkwright and Watt were

elaborating and perfecting their magnificent improvements of the spinning-machine and steam-engine, the British arms were subjecting vast empires in the East to our dominion, countries which possessed within themselves the germs of an almost boundless production; lands which, from their suitability and fertile nature, might well be expected to furnish illimitable food for the new leviathans of steam and iron which they of Lancashire were creating. The varieties of cotton known in the commercial world may be referred to three distinct species, each having several varieties. The *Gossypium barbadense* is the species cultivated in the West Indies, North America, and in one or two parts of the peninsula of India. *Gossypium peruvianum* yields the cotton of Brazil, Pernambuco, Peru, &c. This also has been introduced into some districts of India. *Gossypium indicum* is the species which, in a number of varieties, produces the great bulk of the cotton of India and China. There is a fourth species also, the *Gossypium arboreum*, or Tree-cotton of India, unknown to commerce, though yielding a beautifully soft and silky fibre, admirably adapted for padding cushions, pillows, &c. The Indian species is that which now calls for our remarks. Of this there are many varieties, each possessing some distinguishing character of its own, arising from mode of treatment, soil, climate, &c. It usually attains a height of four to six feet, is bi-triennial, but may be equally cultivated as an annual, germinating and ripening its seed within a period of from four to eight months. The leaves are five-lobed; the flowers are usually found blossoming singly at the extremity of the branches; the petals being of a lively yellow colour, with a small purple spot near the claw. The seeds are five in number, and are clothed with a firmly-adhering greyish down, beneath the short white wool of the capsule. The qualities by which the value of cottons are determined may be confined to three; viz. length of staple, strength of fibre, and cleanness of sample. Colour, which was at one time thought much of, is no longer looked upon as a matter of moment. Inferior as the cotton of India is allowed to be, as regards its staple and purity, there is every reason to believe that in durability it at least equals the produce of any part of America; and of this fact the Hindoos are themselves perfectly aware. In spite of its comparative inferiority, the Chinese have become large consumers of the cotton of India; and from taking a few hundred bales in the early part of the present century, they now consume as much as 50,000,000 lbs. annually. Some quantity is also exported into the neighbouring countries on the north-west of India; and if we add to these outlets the home-demand for the manufacture of a variety of dresses, furniture-trappings, &c. in daily use amongst all classes of the natives, it will be seen that the yearly production of cotton within the Indian territories must be on an enormous scale. It has been stated by Dr. Wight, allowed to be a competent authority on all matters connected with the natives of India, that the average consumption of cotton by the inhabitants of Hindostan amounts to not less than twenty pounds for each person. This will give a local annual consumption of 3,000,000,000 lbs.; and, with the quantities taken by Great Britain and China, a total yearly crop of 3,110,000,000 lbs. As early as the year 1788, the Court of Directors urged the Indian authorities to give every possible encouragement to the growth and improvement of Indian cotton, at the same time ordering a shipment of 500,000 lbs. to be made. Shortly afterwards, screws for the embalement of the article were erected, and a variety of imported seed was distributed throughout the peninsula. From this time until the beginning of the present century the shipments of Indian cotton to England fluctuated between 700,000 lbs. and 3,300 lbs., the price of Surat kinds at Liverpool varying from 2*s.* 5*d.* to 8*d.* per lb. In 1801, samples of the produce of Mauritius and Nankin seeds were received in England: and between that period and 1812 bounties were offered for improved samples, reports were received on the cotton resources of the various districts from the collectors, and quantities of West Indian and American seeds were sent out and distributed through various cotton districts, with copies of instructions carefully compiled. The shipments of cotton to England during this period varied from 27,783,000 lbs. to 694,000 lbs., with prices ranging between 3*s.* and 8*d.* In 1813 and 1814 the war with America broke out: and strange to say, that although our supplies from the United States entirely ceased while hostilities lasted, the receipts of cotton from British India only amounted in those two years to 5,200,000 lbs., or 2,600,000 lbs. per annum. It was at this time that the first American planter was dispatched to India, with the view of aiding in the improved culture and preparation of cotton, taking with him a number of New Orleans sawgins. In 1840, Captain Bayles of the Madras army, having returned from a mission to the southern states of America, brought with him ten planters skilled in the growth and preparation of cotton, a great quantity of the best cotton-seed, as well as a large assortment of agricultural and mechanical implements employed in the States. Experimental culture on a liberal scale was now commenced in the districts of Broach, within the Bombay presidency; in Coimbatore and Tinnevelly, to the south of Madras; and in the Doab and Bundelcund, within the Bengal presidency. These were followed up by similar attempts at various other points within the three presidencies; the American planters were shifted from one locality to another, with a view of testing the comparative qualities of soil; in some instances model plantations were established and worked under the immedi-

ate supervision of these planters; in others, efforts were made to induce the native growers to cultivate some of the American varieties, with the seed of which they were supplied. In all these efforts little expense was spared; yet in spite of the lavish and continued outlay, nothing appears to have been arrived at beyond the conviction that, with but one or two exceptions, much time, labour, and money had been expended without any encouraging results. How far these continued efforts, which have, on the whole, been spread over a period of nearly seventy years, have been attended with success, may be judged from the facts, that in 1848 the shipments of Indian cotton to Great Britain amounted to 84,101,000 lbs., being 4,500,000 lbs. less than in 1844, 13,200,000 lbs. less than in 1841, and 2,400,000 lbs. below the exports of 1818. Taking the average of a number of years, the export of Indian cotton to England shews a sensible increase since the pacification of Europe. Thus the average shipments to Liverpool from the Indian ports during the five years immediately following the peace were 44,000,000 lbs.; whilst in the five years ending 1848 they amounted to 69,000,000 lbs.; in other words, they have averaged an increase of rather more than fifty per cent in thirty-three years. This augmentation, however, sinks into utter insignificance when compared with the progress of the cotton shipments from the United States to England during the same period, which was, in round numbers, from 45,000,000 lbs. to 600,000,000 lbs., shewing an increase of more than thirteen hundred per cent. By far the greater portion of the English supplies of Indian cotton are shipped from the port of Bombay, as may be seen by reference to the following figures:—

From Bombay.. ...	55,201,231	representing an average of 13 years ending 1846.
„ Calcutta.....	1,293,080	
„ Madras.....	3,973,074	
„ Tinnevelly...	1,110,084	

Having thus seen that, at the end of labours spread over seventy years, after a large outlay of money and labour, after the importation of seeds, tools, and superintendence, the quantity of Indian cotton obtained for England amounts to but one sixteenth in value of her total requirements: that in but few respects does the bulk of this excel in quality that which was exported fifty years since; and that the culture of the plant has been very partially extended or improved in the chief cotton-growing districts, scarcely at all in provinces to which that cultivation is less known, —it behoves us to examine into the causes of this wholesale failure. It must be borne in mind that the question of improvement of Indian cotton should be considered under three distinct heads: the introduction of better varieties, the amelioration of the quality and condition of the indigenous produce already grown, and the increased culture of the plant. The opinions of the American planters who were engaged by the East India Company appear to have been that the soils selected for trial of new seed were adverse to the chances of success. That this has been so in several instances, and with some shew of reasoning, there can be little doubt; the black cotton soil has been, in not a few cases, supplanted by the red soil, especially of Southern India, where some success has attended the trials thus made. There does not seem, however, to have been much, if any, attention paid to the peculiarities of climate, the degree of moisture, the temperature, nor of these points taken in connexion with varieties of soil. It will require no argument to shew that conditions affecting the vegetable economy of sugar, coffee, or rice, must be not altogether without their value in regard to the development of the cotton-plant, whether in India or elsewhere. Yet it does not appear that this consideration has entered into the calculations of the many practical men engaged inthe long labours of the cotton experiments of India. It cannot be that, as has been said, any portion of these failures is attributable to the supineness of the agency employed. If the bulk of the experimentalists have been in the employ of government, and therefore not so likely to have taken a lively interest in the matter, what is to be said of the want of success attending private enterprise? All appear to have shared in the common disappointment; and it is clear that we must look elsewhere for causes of failure. Whilst climate and soil, separately or together, have been at work in retardment of new culture or the introduction of new varieties, there are antagonisms to be found in other quarters, affecting not only these, but the improvement of the indigenous cotton by culture, and by care in picking, equally with the increase in the amount of crop produced.—*Capper's Three Presidencies, page* 344.

Indian Cottons.—The species peculiar to the Indian continent in common with other parts of Asia, as distinguishable from the American and West Indian descriptions, is, according to Dr. Royle, the *Gossypium Indicum* or *herbaceum*; the *Gossypium arboreum*, peculiar to India alone, is unfitted for manufacturing purposes, and employed solely as a padding for cushions, pillows, &c., for which, from its silky softness, it is especially adapted. It appears to have been produced in and exported from India since the most remote periods, and during the present century to have assumed a very important position amongst the articles shipped from each of the three Presidencies. Great Britain at the present time takes on an average 90,000,000 lbs. annually. China consumes nearly as much; whilst the native manufacture for local use cannot be less than 600,000,000 lbs. yearly. This vast quantity will cease to cause astonishment, when

re remember that the hundred million of inhabitants of India are accustomed to use cotton or all those purposes for which hemp, flax, wool, nd hair, are employed in European countries. n commerce Indian cotton is known under the ames of Surat, Tinnevelly, Bengal, Broach, &c., ccording to the locality of its growth or place of hipment. Dr. Royle gives three distinct varieies of cotton, all indigenous to Hindostan. The ommon description is found scattered more or ess throughout India, reared either as a triennial r annual. It reaches the height of five or six eet in warm, moist climates; the seeds are five n number, clothed with a short greyish down. n the peninsula there are two distinct species of his sort, known amongst the natives as *Oopum* nd *Nadum*. The first thrives only on the richest lack oil, and is an annual, producing a fine taple; the latter is a triennial plant, and grows n the poorer red soil, yielding small crops of nferior quality. Next to these we have the Dacca cotton, as a distinct variety of the *Gossypium Indicum*. It differs from the previous in he plant being more erect, with fewer branches, nd tinged with a reddish hue, whilst the cotton s finer, softer, and longer. This variety is reared nore or less extensively throughout Bengal especially in the Dacca district, where it is employed n the manufacture of the exquisitely fine muslin loths known over a great part of the world as Dacca muslins, and whose delicacy of texture so ong defied the imitation of the art-manufacturrs of the West. A third variety is the Berar otton, grown also in the Berar country, in the norhern provinces of the Madras Presidency, and n Surat and Broach. This plant attains a greatr size than the preceding, bears for a longer eriod, and produces a fibre of a finer quality han the former. It appears to thrive best n a light black soil of vegetable composition. Amongst commercial men the term *Surat* includes he produce of Surat, Berar, and Broach, with ccasionally some from Dacca; it comes mostly rom Bombay. The Madras cottons are those hipped from Tinnevelly, Coimbatore, and other arts of that Presidency, whilst the Bengals ake in the Bundelcund, Nagpore, and the far orthern provinces. Examined under a microsope the staple of these sorts appears to range rom seventeen-twentieths to one and one-tenth f an inch in length; the staple of the celerated Sea-Island cotton being usually an inch nd a half in length. The soil in which all hese Indian varieties thrive may be classed under two distinct heads, the black and the red cotton soil. The former, as its name indicates, s of a black or deep brown colour, of a layey nature, forming in the rains a heavy enacious mass, and drying into solid lumps in he hot months. An analysis of this gives 4 per cent of silex, 12 of carbonate of lime, 3 protoxide of iron, 3 of alumina, 2 of vegetable matter, and ½ salts, with a trace of magnesia. The red soil of India has been found in some localities better suited to the growth of cotton than the black earth. It is a rather coarse yellowish-red soil, commingled with particles of kunker, silex, felspar, and aluminous earth. It mainly differs in composition from the preceding in the iron existing in the state of peroxide or red oxide, whilst the carbonate of lime is found present in greater abundance. Analyses of the best cotton-soils of America, prove that they differ from those of India chiefly in the large portions of peaty matter contained in them. —*Capper's Three Presidencies, page* 26.

China Cottons. The *yellow Cotton* from which the beautiful Nankin cloth is manufactured is called Tze mie wha by the Chinese. Although the yellow variety has a more stunted habit than the other it has no characters which constitute a distinct species. It is merely an accidental variety, and although its seeds may generally produce the same kind, they doubtless frequently yield the white variety, and vice versa. Hence, specimens of the yellow cotton are frequently found growing amongst the white in the immediate vicinity of Shanghae; and again a few miles northward, in fields near the city of Poushan on the Banks of the yang-tse-kiang; where the yellow Cotton abounds. Fortune often gathered specimens of the white variety.

The *Nankin Cotton* is chiefly cultivated in the level ground around Shanghae, where it forms the staple summer production of the country. This district which is part of the great plain of the Yang-tze-kiang, although flat, is yet several feet above the level of the water in the rivers and canals, and is consequently much better fitted for cotton cultivation than those flat rice districts in various parts of the country,—such for example as the plain of Ningpo, where the ground is either wet and marshy, or liable at times to be completely overflowed. Some fields in this district are of course, low and marshy, and these are cultivated with rice instead of cotton, and regularly flooded by the water wheel during the period of growth. Although the cotton land is generally flat, so much so, indeed, that no hills can be seen from the tops of the houses in the city of Shanghae, it has nevertheless a pleasing and undulating appearance, and taken as a whole it is perhaps the most fertile agricultural district in the world. The soil is a strong rich loam capable of yielding immense crops year after year, although it receives but a small portion of manure. The manure applied to the cotton lands of the Chinese is doubtless peculiarly well fitted for this kind of crop. It is obtained from the canals, ponds, and ditches which intersect the country in every direction and consists of mud which has been formed partly by the decay of long grass, reeds, and succulent water plants, and partly by the surface soil which has been washed

down from the higher ground by the heavy rains. Every agricultural operation in China seems to be done with the greatest regularity, at certain stated times, which experience has proved the best, and in nothing is this more apparent than in the manuring of the Cotton lands. Early in April the agricultural labourers, all over the country, are seen busily employed in cleaning these ponds and ditches. The water is first of all partly drawn off, and then the mud is thrown upon the adjoining land to dry, where it remains for a few days until all the superfluous water is drained out of it, and is then conveyed away and spread over the cotton fields. Previous to this, the land has been prepared for its reception, having been either ploughed up with the small buffalo plough in common use in the country, and then broken and pulverised by the three-pronged hoe, or in those instances where the farms are small and cannot boast of a buffalo and plough, it is loosened and broken up entirely by manual labour. When the mud is first spread over the land, it is, of course, hard or cloggy, but the first showers soon mix it with the surface soil, and the whole becomes pulverised, and it is then ready for the reception of the cotton seed. Road scrapings and burnt rubbish are saved up with care, and used for the same purpose and in the same manner. A considerable portion of the cotton lands either lie fallow during the winter months, or are planted with those crops which are ready for gathering prior to the sowing of the cotton seed. Frequently, however, two crops are found growing in the field at the same time. Wheat, for example, which is a winter crop, is reaped in the Shanghae district generally about the end of May, while the proper time for putting in the cotton seed is the beginning of that month or the end of April. In order, therefore, to have cotton on the wheat lands the Chinese sow its seeds at the usual time amongst the wheat, and when the latter is reaped, the former is several inches above ground, and ready to grow with vigour when it is more fully exposed to the influence of sun and air. The Shanghae season—that is, from the late spring frosts to those in autumn—is barely long enough for the production and ripening of the Cotton, as it is easily injured by frost, and the Chinese farmer is thus obliged, in order to gain time and obtain two crops from this ground in one year, to sow its seeds before the winter crop is ready to be removed from the ground. When it is possible to have the first crop entirely removed before the cotton is sown it is much preferred, as the land can then be well worked and properly manured, neither of which can otherwise be done. The method of sowing one crop before the preceding one is ripe and removed from the land is very common in this part of the country; and even in autumn, before the cotton stalks are taken out of the ground other seeds are frequently seen germinating and ready to take the place of the more tender crop. In the end of April and beginning of May—the land having been prepared in the manner just described the cotton seeds are carried in baskets to the fields and the sowing commences. They are generally sown broad cast, that is, scattered regularly over the surface of the ground, and then the labourers go over the whole surface with their feet and tread them carefully in. This not only embeds the seeds, but also acts like a roller to break and pulverise the soil. Germination soon commences, the seeds rooting first in the manure which had been scattered over the surface of the land. In some cases the seed, instead of being sown broadcast, is sown in drills or patches, but this mode is less common than the other. The rains, which always fall copiously at the change of the monsoon which takes place at this season of the year, warm and moisten the earth, and the seeds swell, and vegetation progresses with wonderful rapidity. Many of the operations in Chinese agriculture are regulated by the change of the monsoon. The farmer knows from experience, that, when the winds, which have been blowing from the north and east for the last seven months, change to the south and west, the atmosphere will be highly charged with electric fluid, and the clouds will daily rain and refresh his crops. The cotton fields are carefully tended during the summer months. The plants are thinned where they have been sown too thickly, the earth is loosened amongst the roots, and the ground hoed and kept free from weeds. If the season is favourable, immense crops are obtained owing to the fertility of the soil, but if the weather happens to be usually dry from June to August, the crop receives a check which it never entirely recovers, even although the ground after that period, should be moistened by frequent showers. 1845 was a season of this kind, and the crop was a very deficient one, compared with that of the previous year. The spring was highly favourable, and the plants looked well up to the month of June, when the dry weather set in, and gave them a check which they never recovered. Abundance of rain fell later in the season, but it was then too late, and only caused the plants to grow tall and run to leaf, without producing those secretions which ultimately go to the formation of flowers and seed. The cotton plant produces its flowers in succession from August to the end of October, but sometimes, when the autumn is mild, blooms are produced even up to November, when the cold nights generally nip the buds, and prevent them from forming seed. In the autumn of 1844 this happened on the night of the 28th of October, when the thermometer sunk to the freezing point, and the ice was found on the sides of the canals and ponds. As the pods are bursting every day, it is necessary to have them gathered with

great regularity, otherwise they fall upon the ground and the Cotton gets dirty, which of course reduces its value in the market. Little bands of the Chinese are now seen in the afternoon in every field, gathering the ripe cotton and carrying it home to the houses of the farmers, As the farms are generally small, they are worked almost entirely by the farmer and his family, consisting sometimes of three or even four generations, including the old grey-haired grandfather or great grandfather, who has seen the crops of four-score years gathered into his barns. Every member of these family groups has a certain degree of interest in his employment; the harvest is their own, and the more productive it is, the greater number of comforts they will be able to afford. Of course there are many cotton farms of larger size, where labourers are employed in addition to the farmer's family, but by far the greater number are small and worked in the way I have just described. It is no unusual sight to see the family goats too, doing their share of the work. Several of these animals are kept on almost every farm, where they are, of course, great favourites with the children, and often follow them to the cotton fields. Although the children with their little hands can gather the cotton as well as their elders, they are not strong enough to carry it about with them, and it is amusing to see their favourites the goats, with bags slung across their backs, receiving the deposits of cotton, and bearing it home to the houses, evidently aware that they too are working for the general good. However fine the crop may be, the Chinese are never sure of it until it is actually gathered in; much depends upon a dry autumn, for, if the weather is wet after the pods begin to burst, they drop amongst the muddy soil, and are consequently much injured, if not completely destroyed. When the cotton reaches the farmyard, it is daily spread out on hurdles raised about four feet from the ground, and fully exposed to the sun. As the object is to get rid of all the moisture, it is of course only put out in fine weather, and is always taken into the house or barn in the evening. When perfectly dry, the process of separating it from the seeds commences. This is done by the well known wheel with two rollers, which, when turned round, draws or sucks in the cotton, and rejects the seeds. It is a simple and beautiful contrivance, and answers well the end for which it is designed. The cotton is now sent to market, and a portion of the seeds are reserved for the next year's crop. Early in the fine autumnal mornings, the roads leading into Shanghae are crowded with bands of coolies from the cotton farms, each with his bamboo across his shoulders and a large sack of cotton swung from each end. With these they hurry into the town, for the purpose of disposing of them to the merchants, who have numerous warehouses from which they send the cotton to the other provinces of the empire. These coolies or small farmers, for many of them bring their own produce to market themselves, are very independent in their dealings. Having reached the first warehouse, the cotton is exposed to the view of the merchant, who is asked what price he intends to give for that particular quality and should the sum offered be below the owner's expectations, he immediately shoulders his load and walks away to another merchant. At this season it is almost impossible to get along the streets near the sides of the river where the cotton ware-houses are, owing to the large quantities of this commodity which are daily brought in from the country. It is bought up by the large cotton merchants, who empty it out in their warehouses, and then repack it in a neat and compact manner before it is conveyed on board the junks. Before the cotton is converted into thread for the purpose of weaving, it is cleaned and freed from knots by the well known process common in our possessions in India. This is done by an elastic bow, the string of which being passed under a portion of the cotton placed on a table, throws it in the air by the vibration which is kept up by the workman, and separates the fibre without at all breaking or injuring it. At the same time the wind caused by the sudden vibrations carries off the dust and other impurities. After this process the Chinese cotton is particularly pure and soft, and is considered by good judges not to be surpassed by any in the world. It is much superior to that imported into China from Hindustan, and always commands a higher price in the Chinese Market. When the last crops are gathered from the cotton fields, the stalks are carried home for fuel. Thus every part of the crop is turned to account: the cotton itself clothes them, and affords them the means of supplying themselves with all the necessaries of life, the stalks boil their frugal meals, and the ashes even—the remains of all—are strewed over their fields for the purposes of manure. But even before this takes place the system I have already noticed of sowing and planting fresh crops before the removal of those which occupy the land—is already in progress. Clover, beans, and other vegetables, are frequently above ground in the cotton fields before the stalks of the latter are removed. Thus, the Chinese in the northern provinces lengthen by every means in their power the period of growth; and gain as much as they possibly can from the fertility of their land. The reader must bear in mind, however, that the soil of this district is a rich deep loam, which is capable of yielding many crops in succession without the aid of a particle of manure. Nature has showered her bounties on the inhabitants of this part of the Chinese empire with no sparing hand; the soil is not only the most fertile in China,

but the climate is capable of rearing and bringing to perfection many of the productions of the tropics, as well as the whole of those found in all the temperate regions of the globe. —*Fortune's Wanderings, from page 264 to p. 273.* The annual importation into China is placed rather too low in the Table, for in 1842, there were 650,000 peculs delivered; and in 1843 there were 817,668 peculs, of which 578,775 were Bombay, 89,201 Bengal, 141,860 Madras, and 8,832 American. The average is about 750,000 peculs of all kinds at $9½ per pecul, giving a total of $7,125,000. The Bombay and Madras cotton trade has increased of late years, and the Bengal decreased; the imports of American are likely to increase. The importation of raw cotton into China is however, on the whole, not likely to increase much under the new system; for the cheapness of the manufactured goods will lead the Chinese to take them, instead of working up the raw material. Cotton is always quoted in taels and mace in China Prices Current.—*Morrison.*

Bengal Presidency.—The muslins of Dacca, so long celebrated, have always been manufactured from a cotton grown to the eastward and south-east of the city of Dacca, and a few miles inland from the banks of the Burrampooter; the plant has been figured by Dr. Roxburgh in vol. 3, t. 269, of his Coromandel Plants. It has often been doubted whether the superiority of the manufacture was dependent on the skill of the workmen or the goodness of the cotton; but from Mr. Lamb's account it appears to be carefully cultivated. It will probably be found that both have some influence, and it is certain that the workmen prefer the Dacca cotton, because, as Mr. Bebb long ago explained, its thread does not swell in bleaching, as is the case with the cotton grown in North Western and Central India. (Vide Reports of East-India Company on Cotton, p. 350.)

Cotton of N. W. India.—Of the cotton which is grown further north, Mr. Duncan, as early as 1789, relates, that the greatest part of the cotton produced in Benares (N. lat. 25°) is spun into thread, as the spinners there prefer such cotton to the generality of that imported from foreign countries. Of this, the cotton imported from Nagpore was held in the highest estimation, and considered nearly equal to that from Surat, though that grown near Benares is described as being very little inferior to it.

Cotton of the Doab and of Bundlecund, 1832. —Dr. Royle in proceeding down the Jumna in January 1832, observed that the cotton plants on its banks, especially below Agra, though smaller, were very prolific bearers, the bolls were larger, and the cotton better than he had seen either higher up or lower down the river. Subsequently, he was informed, that the best cotton was grown in Bundlecund, in the neighbourhood of Jalown, not far inland from Calpee; that the next best was that of Raja-Khera, below Agra. Good cotton is produced all along the banks of the Jumna, as far north as 30°. Mr. Vincent, of Nudjuffghur, stating that, in the tract of country lying to the north of Allahabad, "the produce of a begah (one-third of an acre) is on an average, about a maund of cotton, and two maunds of seed, which is as readily sold as the cotton itself, being an excellent food for cattle."

Cotton of Central India.—The cotton of the interior or Central India, whether we consider the opinions of the native manufacturers on the Madras coast, or those of Benares or Bengal, or the exporters at Bombay, has always been highly esteemed. It was bought also at Dacca, and they paid 19 rupees a maund for the cotton of Sironje in Malwa at the time that their own cotton was selling for about six rupees, which was about the same price, as the former was cleaned and the latter uncleaned cotton. The soil of Central India is peculiar, consisting in many places of the black cotton soil; the climate also differs from that of the Lower Provinces. It is more than probable, therefore, that the causes are physical and may be discovered, which will account for the superiority as well as the facility of culture of cotton in these districts. In such a case, the Delhi Canal affords great facilities and eligible situations. Colonel Colvin introduced the culture of the Upland Georgia cotton into upwards of one hundred villages along its banks.

Bengal.—The Garrow, Tipperah, and Chittagong Hills produce a large quantity of inferior Cotton called Bhoga. It is the principal article of traffic which the hill people bring down to the plains. The quantity annually sold or bartered by the Garrow tribe is estimated at 50,000 maunds; that by the Tipperah Kookees at 1,00,000; and that by the Chittagong people at 50,000 maunds, making a total quantity equal to *two millions* of pounds (15 millions), *vide* Mr. Taylor's letter, 20th November 1849. It is used in the manufacture of the inferior kinds of *hummums*, *baftas*, *boonees*, *sarees*, *jore*, *&c.*, also for making ropes and tapes, and the coarsest of all fabrics, viz. *garhas* and *guzeehs*, which are commonly used for packing other cloths, and for covering dead bodies, for which purpose a large quantity of them is consumed annually both by Hindoos and Mahomedans. This branch of industry has not yet been touched by the rivalry of British manufactures, the thread of which these fabrics are made, being far below the lowest number of English yarn imported into Bengal. A piece of Guzeeh cloth, measuring 10 yards, can be purchased for 12 annas (18 pence) which is the one hundred and twenty-fifth part of the price paid for a piece of *mulmul-i-khas* of the same dimensions.—*Dr. Taylor.*

Tenasserim Provinces.—Mr. Blundell introdu-

ced the Pernambuco cotton plant, *Gossypium acuminatum*, which produces the Pernambuco, Peruvian, Bahia, or South Sea Island cotton; and Capt. Macfarquhar raised such a fine article at Tavoy from it, that the Committee of the Agricultural and Horticultural Society of Calcutta were unwilling to believe it the production of that species. They reported: "The sample sent by Capt. Macfarquhar appears to be of a quality resembling the *Sea Island*, but finer and more silky, and the fibre not so strong, its value is not so easy to determine, but the Committee are of opinion that it would sell for a high price. The Pernambuco cotton, which, it is believed, is the same as the *South* Sea Island cotton, is an inferior staple to that of the North American Sea Island, and they have a sample of cotton submitted which in point of *fineness* surpasses the genuine Sea Island cotton of North America. This improvement on the general staple of Pernambuco cotton might be reconciled, had it been produced *at a distance from the sea*, since it has been ascertained, that this description of cotton deteriorates by proximity to the sea; whence your Committee are disposed to think that Capt. Macfarquhar has been led into error in calling it *South sea* Island instead of Sea Island." Admitting that Captain Macfarquhar was in error, which it is believed he was not, the report proves that an article "finer and more silky," than the best American cotton has been raised in these Provinces. The principal difficulty to the introduction of this species into general cultivation was, as Mr. Blundell told me, that the trees did not produce abundantly.—*Mason.*

Sea Island Cotton.—Sea Island cotton has been raised in these Provinces by amateur cultivators, but Mr. Mason has never seen any report on the article obtained. "Bourbon cotton of Indian growth," says Wight, "has sold in the London markets for the highest prices going;" and, as the Bourbon plant is the original Sea Island acclimatized to the East, the cultivator would have a stronger probability of success by obtaining his seed from Bourbon, than from America. Much attention should also be given to the selection of a proper soil. Analysis has shown that all the lands on which cotton is grown in India, differ widely in their constituent parts from the best cotton land of America. The subject is still in its infancy, more extensive analysis being required; "but it seems *at present*," observes Mr. Piddington, "that the abundance and fineness of good cotton depend on the quantity of carbon in the soil, *and the solubility of that carbon*. If, therefore, you can obtain a soil approaching the American soils, that is, containing peaty matter, lignite, and colouring cold water, this will no doubt be the best; because it contains carbon, and probably hydrogen combined with it, suitable for the food of the plant. And the next best soil is one containing carbonate of lime." The varieties are

Gossypium barbadense. Var. (a) Barbadoes, or Bourbon cotton. (b) Sea Island, or long stapled. (c) Upland Georgia, or short stapled.—Mason.

Native Cotton.—The Karens usually grow cotton enough to make their own fabrics, and on the Salwen and Tenasserim, it is sometimes raised in considerable quantities; but its market price is little more than a fourth of the best American cotton; yet with improved modes of culture, and frequent changes of seed, its value would undoubtedly be greatly increased.

Bombay Presidency.—The Bombay Presidency has long exported large quantities of cotton both to Europe and China. The best cotton districts are widely separated from each other, and at opposite points of the Bombay territory. These are the southern Mahratta country, about 16° N. lat., where the experimental farms were established, because presenting tracts considered by Dr. Lush well suited for the purpose. Guzerat and Cattywar are the districts where the well known superior cottons are already grown by the native; in consequence of which, these were selected as the sites of the northern experimental farms, and much favourable land for the purpose is found between the latitudes of 21° and 24° North. This part of the country was the site of the experiment of Mr. Assistant Surgeon Gilders in 1816-17, who, having observed the causes which led to the failure in the attempt to introduce the cultivation of Bourbon cotton into the western districts, considered the obstacles to have been exclusively of a physical nature. He at the same time stated, that both the soil and climate of the districts lying between the Subermuttee and the Myhee promised a favourable result. The cotton grown, at that time, by Mr. Gilders was considered at Bombay fully equal to any produced in Bourbon, and in London, as the best specimen that had been imported from Bombay raised from Bourbon seed. It sold for 15*d.* per lb. With so much sagacity had Mr. Gilders selected the site of his experiments, that fifteen years afterwards Dr. Burns collected seed from trees growing apparently wild. These being sown, produced plants of which the cotton was pronounced equal to the best from New Orleans. The cotton grown at Laberkowa, within two miles of Mongrole, though confined to a space of 200 beegahs, or thereabouts, was so highly valued, that on the spot it would fetch six-sevenths of a rupee per maund more than any other kind in that part of the country; yet the natives say they frequently used seed from Guzerat, or any part of the country. The superiority must therefore depend either upon peculiarity of soil and climate or excellency of culture. One point only of the latter is related, but that is one of great consequence. For instance, the people are in the habit of carefully extracting the cotton alone from the pod in the field; and this is, probably, of considerable importance, as some of the Ame-

rican planters are of opinion, that the staple of Indian cotton is much injured after it is collected by being allowed to heat when piled up, often for a long time, before it is cleaned.

Madras Presedency.—As early as 1790, Dr. Anderson was employed in sending Mauritius cotton seeds, as well as "Brown Cotton Seeds," imported from Malta, to different parts of the peninsula; and Dr. Roxburgh, who left Samulcotta in the Northern Circars and took charge of the Calcutta Botanic Garden in 1793, had already ascertained that the elevated, dry, and less fertile soil of Coromandel was better suited than that of Bengal to the Bourbon cotton. He obtained them from Mr. Hughes, who had for some time been engaged in the culture of cotton in the Tinnevelly district, and whose success was so considerable with the Bourbon cotton, that for twenty years "Hughes's Tinnevelly Cotton" continued to be quoted in the Liverpool market as the best from India, and sold at higher prices than the American sort staple cottons, and 3*d.* per lb. above the best Surats. The fact is important, on account of the latitude of Tinnevelly being only $8\frac{1}{2}°$, and because the success was evidently the result of skill applied to the culture. The produce, only 100 lbs. per acre, was fine in quality and much esteemed. It would also seem that in Vizagapatam, about north latitude 17°, the return is much greater than in any other district, as the produce is said to amount to "forty-six maunds, or 115 lbs., of seed cotton per acre, nearly equal to the best, and exceeding the ordinary American crops." The culture here is peculiar, as very liberal pruning is practised. In Trichinopoly, with a fertile soil, 83 lbs., which is the next highest, is the greatest return, which, though so much less than the above, is still more than double the average return from other districts. But no reports had then been received from North Arcot, Bellary, and Cuddapah; the two last are stated by Dr. Wight to be the principal cotton districts of the peninsula. The cotton of Central India finds its way on the west to Surat, and on the east to Mirzapore, which has long been the great Cotton mart of that side of India. The causes which favour the growth of Cotton, esteemed both in India and England, in the tract of country extending from Surat and Ahmedabad, or from about lat. 21° and 23°, in a broad band across Malwa to Banda and Rajakhaira, in about 25° and 27°, near the banks of the Jumna, are no doubt physical. The black cotton soil which is spread over a great portion of this tract has undoubtedly a considerable share in producing the effect; but good crops of cotton are produced in some parts where there is no black soil, as immediately on the banks of the Jumna and in the Doab. It will therefore probably be found, that the comparative dryness of the climate after the plant has got well established in the ground, checks the vegetative vigour, and favours the production of prolific fruit.—*Royle's Productive Resources of India.* Cotton plants are mucilaginous, and have been used as Demulcents. The seeds yield Oil, which is sometimes expressed for burning in lamps. Cattle are, however, often fed on the seeds, which are also sometimes employed as manure for Cotton plants. Cotton wool is largely employed, throughout the world, in the manufacture of Cloths. Cotton has been long a popular application to burns. Dr. Anderson (Ed. M. and S. Journ. 1828) directs it to be applied in thin layers, one over the other, and retained by the moderate pressure of a bandage. Pain is allayed, local irritation and blistering diminished or prevented, and constitutional disturbance proportionally obviated. M. Reynaud adopted its application in case of Erysipelas, and M. Mayor employs it as a topical application with Calomel in cases of Ophthalmia. (B. and F. Med. Rev. xx. 463) Cotton, though used chiefly for clothing, is, in India, also employed to a considerable extent for cordage, as, for instance, for tent-ropes, of which so many are required for the use of the army, and made entirely of Cotton, as are the tents themselves. So, Cotton ropes are also employed for many domestic purposes. Specimens were sent to the Exhibition of 1851, both from Calcutta and Madras, and have considerable strength. Some of the native shipping, also, and even a few American ships, are rigged with Cotton ropes; while Cotton canvas is also employed for sails, especially on the coast of Cutch, where some very good is made, and sells for about three and a half annas per yard.—*Royle Fib. Pl. p.* 264.

(2921) COTTON-GRASS. ERIOPHORUM CANNABINUM. Its seeds are clothed at their base with a silky or Cotton like substance with which pillows are stuffed and wicks of candles, as well as paper made. Its name is bhabhur and bhabhuree, and is made into ropes by the mountaineers.

(2922) COTTON MANUFACTURES. A notice of the industry of the Hindoos would be manifestly imperfect without some account of their progress in the manufacture of textile and other fabrics, especially since, in at any rate one of these arts, that of Cotton-weaving, they had arrived at a high state of perfection long prior to any extensive manufacture of the article in Europe. If it be also considered, in reference to this branch of industry, that the natives of India, whilst they so far, and for so long, excelled the skilled craftsmen of the West in the production of exquisitely fine muslins, richly worked and highly ornamented, possessed a raw material confessedly of great inferiority to the cotton imported into England from all other parts of the world, we cannot fail to award them a considerable meed of praise. It required the science of a century, the combined efforts of a

Watt and an Arkwright, to compete successfully with the simple handicraft of the Indian village-weaver; whilst in some of the finer goods, it is still questionable whether the British capitalist can equal the patient productions of the simple Hindoo. The actual date of the birth of cotton-weaving in India cannot be arrived at, though there is little doubt of its high antiquity. The cotton plant being indigenous to the country, we have every right to presume that the uses and value of this admirable production of nature would not have been long hidden from the early Hindoos, especially as the art of weaving flax and cotton was well understood by the Assyrians, Egyptians, and other nations of antiquity. The earliest records which we possess bearing upon the people and produce of India, inform us of the existence in those remote days of woven cloths of great excellence. One of the oldest Greek authors, in speaking of the land of the Hindoos, says; "The wild trees of that country bear fleeces as their fruit, surpassing those of sheep in beauty and excellence; and the Indians use cloth made from those trees." Amongst the goods which appear to have been brought to Europe from the Indian seas, in the days when Arab traders were the only medium of intercourse between the eastern and western worlds, we find mentioned cloths of silk and cotton of various colours and devices. It does not appear however, that there existed any great demand for cotton, the consumption of the Roman people, who were then the customers for all luxuries, being chiefly confined to cloths of silk and wool. During the early trade of Europeans with India by the long sea route, the calicoes and fine muslins of that country came first into general notice; and from that date until the production of machine-made fabrics in England, they continued to rise in public estimation. It was deemed a great thing with the Lancashire manufacturers, when, by the aid of mechanical and artistic skill, combined with the potent agency of steam, they found themselves able to produce an article which was considered equal to that which the unlettered Hindoo had manipulated in his little mud hut on the remote banks of the Ganges, and which had been produced of like excellence by their ancestors, when the "father of history" penned his observations upon their country. That the Hindoos paid considerable attention to the details of this manufacture, in the most remote ages, there remains sufficient proof on record. In the Indian work of highest antiquity, the *Rig Veda*, believed to have been written fifteen centuries previous to our era, occurs the following passage, "Cares consume me, Satakralu, although thy worshipper, as a rat gnaws a weaver's threads:"—the temptation to the rat was evidently the starch employed by the spinner to impart tenacity to the thread; nor can there be any doubt that cotton was the thread alluded to.

Again, in *Menu*, we find it directed as follows: "Let the weaver who has received ten palas of cotton-thread, give them back increased to eleven by the rice-water (starch), and the like used in weaving; he who does otherwise shall pay a fine of twelve panas." The cotton fabrics of India formed a considerable item in the exports from the East to this country during the early days of British Indian commerce; the delicacy of their fabric, the elegance of their design, and the brilliancy of their colours, rendered them as attractive to the better classes of consumers in England, as are, in the present day, the shawls of Cashmere or the silks of Lyons. So much superior indeed were the productions of the Indian spinning-wheel and hand-loom, to those turned out by the manufacturers of Lancashire in the middle of the last century, that not only were Indian calicoes and Indian prints preferred to the home-made articles, but the Manchester and Blackburn weavers actually imported Indian yarns in large quantities for employment in their factories. It was about the year 1771-2 that the Blackburn weavers, taking advantage of the recent discoveries and improvements of Arkwright, Hargreaves and others, found themselves in a position to produce plain cotton goods, which, if they did not quite equal the fabrics of the East, at any rate found their way very rapidly into general consumption in Europe. The invention of the mule-jenny, in 1779, was the commencement of a new era in the history of the cotton manufacture of Great Britain; and when, six years later, Arkwright's machines were thrown open to the public, a revolution was effected in the production of all kinds of yarns; England found herself able, not only to supply all her own wants with cotton goods of every variety of quality, but also to carry the produce of her looms ten thousand miles across the seas, and placing them at the doors of the Indian consumer, undersell the goods made by his own hands from cotton grown in his own garden. Nor is it only in the heavier goods that the West are able to beat out of their own markets the weavers of the East. There have long been masters in their craft who can and do produce fabrics more exquisitely delicate and light in texture than those beautiful muslins of Dacca, so long and justly celebrated with a world-wide fame; and although in some particulars these latter fabrics still claim a certain degree of superiority, and although many of the Hindoos prefer their own woven goods to those of Manchester and Glasgow, the cotton manufacture of British India, in spite of its supply of the raw material growing often close to its door, in spite of labour absurdly cheap, may truly be said to have ceased in favour of the far-off industry of Lancashire and Scotland. The actual result of this revolution of half a century has been that, in place of England importing cotton goods and

yarns from the East to the yearly value of about 300,000*l.*, that country is able, in the present day, to ship to the various ports of India cotton fabrics to the value of upwards of three millions sterling. The decay of this branch of our Indian exports has been steady and certain. In 1827,8, Bengal shipped but to the value of 275,000*l.*; in 1837-8, not more than 69,000*l.*; and at the present moment our supplies from the East are limited to about five thousand bales from Madras, solely for re-shipment to our western colonies, and various parts of northern and western Africa. Dacca was the seat of manufacture of the muslins known by that name, and spoken of by the ancients as "woven webs of hair." The most delicately worked and highly ornamented scarfs and dresses are wrought at Delhi, Benares, and Ahmedabad. Fine goods were also produced at Allahabad, Harripaul and Santipore; whilst the more substantial and useful fabrics were wrought chiefly at Patna, Luckpore, Lucknow, Balasore, Masulipatam, Cuddalore, and Surat.—*Royle, Arts of India.* Of the Arts practised at Dacca, the first that claims attention is the Cotton Manufacture. In a commercial point of view, this is no longer the important branch of industry that it formerly was; but, regarded as an Art which furnishes exquisite specimens of textile fabrics, it is still unrivalled. The implement used in spinning and weaving indeed, is rude, but the simplicity of its construction contrasts with the delicate Gossamer texture of the fabrics made by means of it, and shew that the skill displayed in this Manufacture is less the result of artistic ingenuity or complicated mechanical appliances than of that dexterous use of the hand and foot, and delicacy of touch which are possessed, in so remarkable a degree, by the Hindoo Artisans of Bengal. With their rude implements, the Hindoos of Dacca succeed in manufacturing Muslins, "to which," as Dr. Ure observe, "European ingenuity can afford no parallel, such indeed as has led a competent judge to say, it is beyond his conception how this yarn, greatly finer than the highest number made in England, can be spun by the distaff and spindle, or woven by *any* Machinery." (Ure's Cotton Manufacture of Great Britain, Vol. I, p. 54.) There is the primitive instrument used for carding the fibres of the Cotton, likewise the instruments employed for separating the Wool from the seeds, and for bowing or teazing the former. The first is simply the jaw-bone of the Boalee fish (Silurus Boalis), the teeth of which being fine, recurved and closely set, act as a fine comb in removing minute particles of earthy and vegetable matter from the Cotton. The Hindoo Spinner, with that inexhaustible patience that characterizes her race, sits down to the laborious task of cleaning with this instrument the fibres of each seed of cotton. Having accomplished this, she then separates the wool from the seeds by means of a small iron roller (dullun kathee) which is worked with the hands, backward and forward, on a small quantity of the cotton seeds placed upon a flat board. The Cotton is next bowed with a small bow of bamboo strung with a double row of catgut, muga silk, or the fibres of the plantain tree twisted together; and having been reduced by this instrument to a state of light downy fleece, it is made up into a small cylindrical roll (puni) which is held in the hand during the process of spinning. The spinning apparatus is contained in a small basket or tray not unlike the catheters of the ancient Greeks. It consists of a delicate iron spindle (tukooa), having a small ball of clay attached to it, in order to give it sufficient weight in turning; and of a piece of hard shell imbedded in a little clay on which the point of the spindle revolves during the process of spinning. With this instrument the Hindoo women almost rival Arachne's fabled skill in spinning. The thread which they make with it is exquisitely fine, and doubtless it is to their delicate organization and the sensibility with which they are endowed by nature, that their inimitable skill in their art is to be ascribed. The finest thread is spun early in the morning before the rising sun dissipates the dew on the grass, for such is the tenuity of its fibre that it would break, if an attempt were made to manufacture it during a drier and warmer portion of the day. The cohesive property of the filaments of Cotton is impaired by high temperature accompanied with dryness of the air, and hence, when there is no dew on the ground in the morning to indicate the presence of moisture in the atmosphere, the spinners impart the requisite degree of humidity to the cotton, by making the thread over a shallow vessel of water. Skeins of fine thread of different qualities, with a memorandum of the length, weight, and time occupied in spinning, attached to each skein, should be submitted for exhibition. A specimen which Dr. Taylor examined at Dacca in 1846, measured 1,349 yards and weighed only 22 grains, which is in the proportion, of upwards of 250 miles to a pound weight of staple. During the process of preparing the thread and before it is warped, it is steeped for a couple of days in fine charcoal powder soot, or lampblack mixed with water, and after being well rinsed in clear water, wrung out, and dried in the shade, it is rubbed with a sizing made of parched rice, (the husk of which has been removed by heated sand) fine lime and water. The loom is light and portable and could easily be erected for exhibition. It should have for this object, a piece of half finished fine Muslin wound upon its cloth and yarn beams, and be provided with batten, templet, and shuttle, and all the appurtenances requisite to illustrate the process of weaving. The principal varieties of plain Muslins now manufactured at Dacca, are Mulmul Khas, Abru-

wan, Shub-num, Khasu, Jhuna Circar Ali, Tunzeb, Alabullee, Nyanzook, Buddun Khas, Turundum, Surbutees and Surbund—names which either denote fineness, beauty or transparency of texture, or refer to the origin of the manufacture of the fabrics, or the uses to which they are applied as articles of dress. The finest of all is the Mulmul Khas, (literally Muslin made for the special use of a Prince or great personage). It is woven in half pieces, measuring 10 yards in length, and 1 yard in breadth, having 1,900 threads in the warp, and weighing 10 Siccas, (about 3¾ ounces Avoirdupois.) The finest half piece that I have seen weighed 9 Siccas. The price is 100 Rupees. Some of the other Muslins are also beautiful productions of the loom, as *ab-rawan*, compared by the Natives from its clear pellucid texture to "running water." Shub-num, so named from its resemblance when it is wetted and spread upon the bleaching field to the "evening dew" on the grass. Jhuna a light, transparent net-like fabric, usually made to order, and chiefly for natives of rank and wealth, worn by the inmates of zenanas and dancers, and apparently the cloth referred to in the Classics under the figurative names of *Tela Arenarum*, *Ventus Textilis*. All these Muslins are made in full pieces of 20 yards in length by 1 in breadth, but varying considerably in the number of threads in the warp, and consequently in their weight. Of figured fabrics, as striped (*Doorea*), chequered (*Charkanee*), and flowered (*Jamdanee*), there exists a considerable variety, both in regard to quality and pattern. The flowered Muslin was formerly in great demand both in India and Europe, and was the most expensive manufacture of the Decca Urungs. There was a monopoly of the finer fabrics for the Court of Delhi: those made for the Emperor Aurungzebe cost 250 Rupees per piece. This Muslin is still much admired, but is now seldom manufactured of a quality of higher value than 80 Rupees per piece. Omitting the second rate kinds of Cloth, as *Sarees*, *Boonees*, *Baftas*, *Joru*, *Ekpattus*, *Gamchas*, &c., now entirely made of English yarn, imported into the District, and which constitute the great bulk of the Dacca Cotton manufacture. The next class worthy of attention is that of fabrics of a mixed texture of cotton and silk. They are designated by various names, as *Nowbuttee*, *Kutan*, *Roomee Apjoola* and *Lucka*, and when embroidered with the needle, as many of them frequently are, they are called Kusheedu. The silk used in their manufacture is the indigenous Muga Silk of Assam and Sylhet, but the Cotton thread employed is now almost entirely English yarn, of qualities varying from No. 30 to 80. These Cloths are made exclusively for the Jedda and Bussora Market, and a considerable stock is yearly imported in the Arab vessels that trade between Calcutta and these ports. Pilgrims too, from the vicinity of Dacca, not unfrequently take an investment of them, which they dispose of at the great annual fair held at Meena, near Mecca. They are used by the Arabs chiefly for turbans and gowns. The golden color of the Muga silk gives to some of these a rich lustrous appearance. Pieces, made of Native spun cotton thread, and of the best kind of Muga silk, would, I have no doubt, be admired in England.—*Dr. Taylor*. The Export-trade of the Madras Presidency in Madapollams and Long Cloths has been annhilated by the British Manufacturer, and the goods are laid down by him in all the bazars of India. The export-trade of what were denominated Madapollams and Punjums for the 10 years from 1815-16 to 1824-25 was as follows.

	Bales.	Pieces.	Value Rs.
1815-16	11,925		37,82,859
1816-17	10,243		33,53,243
1817-18	9,905		32,78,330
1818-19	7,715		24,00,543
1819-20	5,903		19,64,006
1820-21	5,149		16,81,551
1821-22	2,915		12,53,383
1822-23	541	53,220	409,337
1823-24	„	142,470	793,208
1824-25	„	128,400	802,600

This description of Goods is not now made, and pieces of Punjum are only interesting as specimens of that important manufacture which formerly was to be found in bales in the bazar and in the Custom House for shipment. The same causes which have contributed to so great a falling off in the Cotton Manufacture of the Madras Presidency produce alike upon they arns spun by hand, the change may be perceived by referring to cotton twist imported from the United Kingdom in the years from 1826 to 1830 compared with the last 10 years.

1826-27	13,296
1827-28	17,573
1828-29	96,517
1829-30	49,110
1830-31	10,549
Total	187,045
1844-45	1,178,648
1845-46	755,464
1846-47	953,477
1847-48	517,067
1848-49	375,250
1849-50	673,387
1850-51	786,544
1851-52	10,62,223
1852-53	10,16,703
1853-54	11,05,181
Total	84,23,944

It is however worthy of remark that even the skill and capital of England has not been able to compete in a certain class of fabrics with the manufactures of this Presidency in the home

market, or even to exclude them from the Foreign. This does not arise from any distaste upon the part of natives to wear articles of European manufacture, but consequent upon Europe not being able to supply a white or dyed article, usually worn by natives, as cheap as it can be manufactured in the country; proving that there are bounds even to the power loom, and that fabrics coarse in quality can still be made by the hand at a profit, for, after a fair trial, the weavers of Europe have given up competition in this description (Native Cloths) of fabrics finding their exportation to India not remunerative. It is generally supposed that the power looms of England have destroyed the export Trade of Madras, but the annexed Table demonstrates that such is not really the case; for though a certain description of Goods have ceased to be exported, yet on the whole there is no very extraordinary difference in value between the Export of Cotton Piece Goods, in what were considered the palmy days of the Export Trade, compared with those of the last ten years.

1844-45	3,841,982
1845-46	3.926,438
1846-47	4,286,921
1847-48	3,736,055
1848-49	2,843,425
1849-50	3,097,558
1850-51	2,942,874
1851-52	2.908,934
1852-53	3,521,516
1853-54	3,141,024

TheCotton Twist imported from the UnitedKingdom may in round numbers be taken at 400 bales per annum, each bale will make about 3000 yards of the native cloths usually worn, which would give 12,000,000 (twelve million) yards annually manufactured, irrespective of goods made by yarn spun by the hand. The amount thus given is an estimate that approximates to the truth with sufficient accuracy to exhibit the great extent to which handloom weaving is still carried on in this Presidency. The Cotton Piece Goods submitted for the consideration to the jury comprised only a portion of the varieties of this staple of the Madras Presidency.—*M. Ex Jur. R.* In Ganjam is fabricated a Cotton cloth, each side of a different colour. This effect is produced not by dyeing the cloth after it is woven, but by a dexterous manner of throwing the woof across the warp on either side. Maddapollum and Ingeram used to be famous for Cotton cloths, but since the abolition of the Company's trade, the finer Punjums have not been made, Palumpores, as bed coverings, of the former place deserve attention:—very fine Muslins are made at Copada, North of Cocanada, and handsome Turbans, with gold thread interwoven—but all these things are far surpassed by the Bengal fabrics. The Chicacole Muslins would be however worth attention and are much prized by ladies. Cotton Cloths from Nellore consist of manufactured articles which find a ready sale in the markets of this Presidency.—*M. E. J. R.*

(2923) COTTON SEEDS.

Cuppasia, Guz. Hind.

Are chiefly used in India for feeding cattle, and also sometimes as manure for cotton plants. An oil is expressed from the seed which is used for burning in lamps, and is also considered to have, in a peculiar manner, the virtue, when externally applied, of clearing the skin of spots and freckles.—*Faulkner.*

(2924)COTTON, SILK.The Silk Cotton. The naturalfamily of *Byttneriaceæ*, includes such genera as *Bombax*, *Sterculia*, *Abroma*, *Guzuma*, &c., and like that of the Mallow-worts, inhabits hot parts of the globe chiefly, and also, like it, contains a number of plants remarkable for abounding in mucilage and in fibrous bark. Of these, some are employed for cordage in different parts of the world, and of them a few, as *Abroma augusta*, might probably be grown with greater profit, and yield a better product, than some of those which are now in cultivation. Thus the species of Bombax, which are remarkable for their gigantic stature and their splendid inflorescence, are also so on account of their capsules, which, on bursting, display a flocculent substance, often mistaken by travellers for cotton, and the tree is hence called *Cotton tree*. But as this substance is more silky than cotton, it has been distinguished by the name of *Silk Cotton*. It differs also in not spinning like cotton. Some difficulty, therefore, isexperienced in making use of this very abundant cotton-like produce; but Mr. Williams, of Jubbulpore, has succeeded in spinning and weaving some of it, so as to form a very good coverlet. It might be easily made use of for stuffing pillows, muffs, or coverlets, for wadding, or for conversion into half-stuff for paper-makers, perhaps for making gun-cotton. In the 'Trans. of the Agri-Hortic. Soc.,' iii, p. 274, there is a report from the Society of Arts on two pieces of cloth made from the Simool or Silk Cotton tree; and it is observed that, from the shortness of the staple of the down, and its elasticity, it could not be spun by cotton-spinning machinery.—*Royle's Fib. Plants.*

(2925) COTTUS (Linnæus), a genus of Fishes belonging to the section *Acanthopterygii* and family *Loricati* (Jenyns).—*Eng. Cyc. p.* 174.

(2926) COTULA. *Compositæ.* Cotula Aurea.—This is a common plant with little golden-ball like flowers, and is cultivated in any garden soil, by seed.—*Riddell.*

(2927) COW-DUNG AND BRATTIES.

Peda also Gomayam, Tel. | Shanie, Tam.

Bratties are dried cowding cakes. With water, cowdung forms a useful wash for walls, floors, and

it enters into the composition of the farriers' fomentations: it hides bad joinery, its chief use is in forming *bratties*. The ground cropped by cattle and which supplies straw, ought to receive it back before it is reduced to ashes: till this is done, lands must be unduly exhausted. Bratties ,(piddacalu *Tel.*) are the cowdung cakes dried in the sun: occasionally the cowdung is mixed with the husk of paddy and frequently with earth. This fuel is much used in Southern India for burning bricks and chunam, also for heating iron tyres for tyring wheels, for which purpose it answers better than any other. It is in general use among natives of that part of the East as fuel, being more economical than any other they are accustomed to: it has disagreeable smoke but when thoroughly ignited, the heat they give out is very intense.—*Rhode M.S.S.*

(2928) COW BEZOAR, and bezoars from all ruminating animals, always find a ready market in China, where the doctors lay it up as a rare medicine, and are not unfrequently deceived by an artificial preparation of pipe-clay and ox-gall mixed with a little hair.—*Williams' Middle Kingdom, Vol.* II. *page* 406.—*See* BEZOAR *and* CALCULUS.

(2929) COWHAGE, COWITCH,

Kosambiliwail, CYNG.	Rawe, JAV.
Kaunchkoori, DUK.	Atmagupta, SANS.
Cowage, FR.	Poonaykalie, TAM.
Kuhkratze, GER.	Peelia-dugookaila, TEL.
Kiwach, HIND.	

The short, bristly, brown hairs, which covers the pod or bean found growing on the *Mucuna pruriens*. The plant is a native of India, as well as of several other countries. The hairs are administered in the treatment of worm cases. Cowhage is occasionally exported from Bombay to London in small quantities.—*Faulkner.* Cowhage, probably a corruption of Alkooshee, the Arabic, or Kiwach the Hindustanee and Bengali name of one of the plants that produces it, consists of the hairs found upon the pods of different species of *Mucuna*. They are exceedingly slender, brittle, and easily detached, and the fragments readily stick into the skin and produce an intolerable itching; hence they are frequently employed for mischievous purposes. Cowitch is also used medicinally as a vermifuge, by being mixed with syrup till of the consistence of honey, and given in doses of two or three tea spoonfuls. The plants that bear these pods are large twining annuals or perennials, with leaves like those of kidney-beans, being dark purple papilionaceous flowers, with a short standard lying close upon the wings and keel, and diadelphous stamens, half of which have round and half arrow-headed anthers. The pods contain from one to six seeds, and are covered by a very wrinkled, shriveled skin, which even stands up in little plates. Before they are ripe and their hairs hardened, the pods are employed as a vegetable, like kidney-beans, and are described as being delicious. The species are found in hedges, thickets, on the banks of rivers, and about watercourses in both the East and West Indies, and America within the tropics. *Mucuna urens* and *M. pruriens* usually furnish the substance; but that from *M. monosperma*, called by the Telingas Enooga dola Gunda, or Elephant's Scratch-Wort, is said to exceed the others in the irritating burning property of its hairs. Dr. Roxburgh states that *M. pruriens* was one of the plants formerly used in India to poison wells; "it has turned out, however, not to be the poison it was taken for, and it is more than likely that the other plants employed for the same base ends are fortunately much less dangerous than those who employ them imagine."—*Engl. Cyc. p.* 177.

(2930) COW-TREE, a Plant belonging to the natural order *Urticaceæ*, and apparently to the genus *Brosimum*, from which, when wounded, a milky nutritious juice is discharged in such abundance as to render it an important object to the poor natives in whose country it grows. It is described by Humboldt as being peculiar to the Cordilleras of the coast of Caracas, particularly from Barbula to the lake of Maracaybo, near the village of San Mateo, and in the valley of Caucagua, three days' journey east of Caracas. In these places it bears the name of Palo de Vaca, or Arbol de Leche, and forms a fine tree resembling the Star-Apple of the West Indies. "Its oblong pointed leaves, rough and alterante, are marked by lateral ribs, prominent at the lower surface, and parallel; they are, some of them, ten inches long." Its flowers and fruit have not been seen by any botanist. From incisions in its trunk flows a glutinous milk, similar in consistence to the first milk yielded by a cow after calving. It has an agreeable balsamic smell, is eaten by the negroes, who fatten upon it, and has been found by Europeans, perfectly innocuous. In chemical characters it is remarkably similar to the milk of animals, throwing down a cheesy matter, and undergoing the same phenomena of putrefaction as gelatine. Humboldt supposed the Cow-tree to belong to the Saponaceous order; but, though little has been added to our knowledge of it since his visit to the Caracas, it is at least certain that it is either a species of *Erosimum*, or very nearly related to it, and consequently a member of the Urticaceous order. The latter circumstance renders the Cow-tree still more interesting; for the milky juice of Urticaceous plants is in other cases highly poisonous. But botanists are now acquainted with many instances of innocuous plants in poisonous order; thus the Hya-Hya Tree of Demerara, for instance, belonging to the deadly Apocynaceous Family, yields a thick rich milky fluid destitute of acrimony; and the Kiriaghuna plant of Ceylon is a sort of East

Indian Cow-Plant, notwithstanding it belongs to the Asclepiadaceous Order, which is acrid and dangerous. In the absence of precise information as to the circumstances under which the Cow-trees are milked, it is impossible to say what is the cause of their harmlessness; but every physiologist will see that it is capable of being explained without difficulty in more ways than one.—*Engl. Cyc. page* 178.

(2931) COWRIES

Kauris, Dut.	Bucios Zimbos, Sp.
Coris, Cauris, Bouges, Fr.	Beya, Sans. Jav. Mal. Beng.
Kauris, Ger.	
Cowrie, Guz. Hind.	
Cori, Porcellanne, It.	

Are small, white, or yellow glossy shells, found in abundance on the shores of the Laccadive and Maldive Islands, African Coast, Zanzibar, &c. There are several varieties; the commoner kinds pass current as coin in payment of fractional parts of a *pice* in Hindustan, and some parts of Africa. They are brought to Bombay in large quantities from the above named places, and are re-exported to England, where they are used in inlaying and ornamenting toys, work-boxes, &c. and in the manufacture of the superior kinds of porcelain-ware. Cowries are brought, in exchange for rice, from the Maldive Islands to Bengal, and thence shipped to England: they were, during the slave trade, exported from Bombay to Africa, where they are also employed as coin.—*Compend. Desc.* The Cypræa moneta of naturalists, is found in the Asiatic Archipelago, but in considerable quantity only on the shores of the Sula group of islands; but the cowry seems never to have been used for money among the Indian islanders as it has immemorially been by the Hindus. The Malay and Javanese name however is Sanscrit, beya, and is also one of the synonyms which express duty, impost, or toll.—*Crawfurd's Dictionary, p.* 117.

(2932) CRAB, SEA CRAB.

Kaddil Nundoo. Tam.	Punjpaiyeh, Pers.
Duryakakekra, Duk.	Katan, Malay.
Kevnkera, Hind.	Samoodrapoo Nundrakaia, Tel.
Khirchung, Arab.	

Cancer Pagurus.—*Ains. Mat. Med. p,* 12.

(2933) CRACKERS, &c. The largest proportion of Chinese fire crackers go to the United States; some are shipped to India and South America. They are made up in strings, and then in papers, and lastly in boxes, five of which are estimated to weigh one pecul. The market of Canton is chiefly supplied with fireworks from Fatshan.—*Compendious Descrip.*

(2934) CRANE. The ridge or keel of the breast-bone, common to all birds that fly, is in the Cranes, belonging to the restricted genus *Grus*, and in the Trumpeter Swans, expanded so as to form a cavity, which the windpipe is prolonged to enter and reproceed from, after describing a vertical convolution therein. Mr. Yarrells's figure of this curious structure, as it exists in the Hooper Swan (*Cygnus musicus*) is, in a general way, illustrative of it, as observed in the *buccinator*; the trachea even performs a second vertical convolution: while in the second wild Swan of North America (*C. americana*) and in the nearly affined Bewick's Swan (*C. Bewickii*), it is prolonged to form a horizontal loop in the body of the sternum, posterior to the vertical convolution within the keel,—that is, in general, for several of Bewick's Swans do not differ in this respect from the Hooper Swan, albeit of full age and development, to all appearance. In a newly hatched Hooper Swan examined, not even an indication of the peculiar structure described could be detected: nor does it occur in the two species of Crowned Crane (*Balearica*), nor in the Mute Swans (*Cygnus olor, C. immutabilis, C. atratus, C. nigricollis*), nor probably in the *C. coscoroba* of South America; but the Crowned Cranes exhibit one curious anomaly in the organ of voice, which is that the long tendinous muscles, the office of which is to contract the windpipe, and which are known as the *sterno-tracheales*, from their ordinary mode of attachment, are not fixed, as usual, at their lower extremities to the sides of the breast-bone, but to the middle of the first pair of ribs! The *sterno-tracheal* muscles are wanting to the 'Adjutant' and most other Storks, and in a very few other birds, such as the Condors (*Sarcorhamphus*) of the Vulture family; indeed the Vultures generally are among the most silent of the feathered creation, emitting no sound beyond a feeble cackling and snorting in their eagerness over their prey.

(2935) CRANGONIDÆ, a family of *Crustacea* belonging to the division *Decapoda Macroura*. The type of this family is the Common Shrimp (*Crangon vulgaris*), and no other genera are included in it. *C. vulgaris, the Common Shrimp*, has the Carapace and abdomen almost entirely smooth, with the exception of one small median spine on the stomachal region.—*Engl. Cyc. page* 188.

(2936) CRAPE.

Crepe, Fr.	Espumilla, It.	Flior, Rus.
Flohr, Ger.	Sendal, Port.	Crespon, Sp.

A light transparent stuff made of silk, gummed and twisted on the mill, and woven without crossing.—*Faulkner.*

(2937) CRATÆGUS, a genus of Plants belonging to the natural order *Rosaceæ* and the sub-order *Pomeæ.—Engl. Cyc. p.* 190.

(2938) CRATÆVA, a genus of Plants belonging to the natural order *Capparidaceæ.—Engl. Cyc. p.* 191. Of the genus Crataeva we may notice the *C. gynandra*, a native of the West Indies. The bark of the root is said to blister like cantharides. The *C. tapia* (*vern.* Birmike chawl

Tapia and Varana, *Sans.*, Garlic Pear, *English*,) is a native of Ceylon, also common in Malabar. The juice of the astringent bark is used as a tonic, and febrifuge. The *C. religiosa* is common in India. The leaves are called Bel-ka-pat, and are slightly bitter and aromatic, and much used by native practitioners. The *C. marmelos* (Bilva or Mahura) formerly considered a species of this genus, is now referred to the order Aurantiaceæ, and call *Ægle marmelos.—O' Shaughnessy, p.* 296.

(2939) CRATÆVA RELIGIOSA. Vahl.

Veelvei elley, TAM.	Bilva akoo, TEL.
Bel ka paat, DUK.	Beelva, SANS.—*Ainslie.*

Leaf of the Religious Cratæva. In the Deckan, this tree is generally found near tombs and temples, the leaves are somewhat aromatic.—*Riddell.* The leaves are somewhat aromatic, in a slight degree bitter, and are considered by the native practitioners as stomachic. The root, as it appears in the bazars, has a singular sub-aromatic and bitterish taste, and is supposed to possess alterative properties.—*Ains. Mat. Med. p.* 124. An infusion of Bel is slightly bitter and aromatic, and much used by the natives of Bengal. Its dose is two to four ounces thrice daily. —*Beng. Phar. p.* 298.

(2940) CRATÆVA ROXBURGHII. *Capparideæ.*

Mavilinghum puttay, TAM.	Tellavoolemara chettoo. T.
Birmike chawl, DUK.	Varoona, SANS.
Maredoo puttay, TEL.	Cratæva tapia, *Ainslie.*
Mavoolinga marum, TAM.	

Bark of the smooth Cratæva. This is the Cratæva tapia of Ainslie, not of Linnæus; Dr. Wight is unacquainted with the timber which Ainslie states to be used for many common purposes.—*Wight.* The Vyteans prescribe the juice of the astringent bark of this large tree, as a tonic in Intermittent Fever, and in Typhus, a decoction of the bark itself is also used for similar purposes. The tree is the Nurvala of the Hort. Mal.—*Ains. Mat. Med. p.* 89.

(2941) CRAYON. A material composed of shell-lac, naptha, and some colouring matter, used for drawing.—*Faulkner.*

(2942) CRESS, GARDEN.

Reshad, ARAB.	Huleem, Chunser, GUZ.
Huleem, BENG.	HIND.
Cresson, FR.	Turehtezak, PERS.

The leaves of the water cress (*Vern* Lootputiah), are gently stimulant and diuretic. As a salad, they are wholesome and palatable, and eminently serviceable to persons affected by scorbutic diseases. Cress should be sown thick in very narrow drills, about one inch deep and a few inches apart. It requires to be well watered, and is in season all the year round. It is only used for salad. The seed is sold in the bazars, and known by the name of Hallim: it should be cut for use when two inches high.—*Riddell.*

(2943) CRESS, AMERICAN OR BELLEISLE. Has a harsh flavour; but owing to its being of a more robust nature than the garden cress, might be easier cultivated on the plains. It is raised from seed, the young leaves cut when young are used for salads; requires plenty of water.—*Jaffrey.*

(2944) CRESS, LEPIDIUM SATIVUM, GARDEN CRESS. Should be sown broad cast in a bed raised above the level, does little good at Madras, though an excellent ingredient in salads.—*Jaffrey.*

(2945) CRESS, NASTURTIUM OFFICINALE, WATER CRESS. This is of easy culture, and should be in every garden, requires to be irrigated night and morning direct from a well; a small bed 2 or 3 yards square, so formed as to be easily irrigated, will produce sufficient for any family during the cold months, the soil near the surface should be somewhat sandy: propagated by seed and division of the plants.

(2946) CRESS SEED.

Hurcef, ARAB. BENG. GUZ. HIND.	Aliverie, Saliverie, TAM.
Rohitasarashupa, SANS.	Adala-Vittiloo TEL.

The seed is of a reddish colour, and agreeable, warm taste; and is used by native practitioners as a gentle stimulant; also as a warm aperient when bruised and mixed with lime juice. The seeds are procurable in most Indian bazars.

(2947) CRINUM, a genus of Plants belonging to the natural order *Amarillidaceæ.—Eng. Cyc. p.* 195.

(2948) CRINUM ASIATICUM, Lin.

Veshei Moonghe elley, TAM.	Veshamandalum, SANS,
Veshamangalapakoo, TEL.	

The succulent leaves of this plant are about two inches broad and two or three feet long. The Natives bruise and mix them with a little warm Castor oil, and consider them extremely useful for repelling whitlows, and other inflammations, on the ends of the fingers and toes.—*Ainslie's Mat. Med. p.* 301. The bulbs of this plant are powerfully emetic, and are used in Hindustan for the purpose of producing vomiting after poison has been taken, especially that of the Antiaris. It is a native of the East Indies.—*Eng. Cyc. p.* 195.

(2949) CRINUM AMABILE, has a very large bulb with a long red neck, the leaves broad, glaucous; smooth at the edge. This plant is a native of the East Indies, but is now common in our greenhouses. Many of the species have been lately introduced.—*Eng. Cyc. p.* 195.

(2950) CRINUM. WATER CRINUM. Many of the clear mountain streams of Tenasserim, where they rest their waters in little crystal lakes, are covered with a fragrant and beautiful species of crinum with long narrow leaves.—*Mason.*

(2951) CRINUM. CRINUM BULBS. A dried fragrant substance is seen in Tenasserim among the native drugs, which is imported. No one seems able to tell what it is, but on tracing its Burman name through the Pali into the Sanscrit, I find Prof. Wilson defines it, with some doubt, as the bulb of a species of crinum.—*Mason.*

(2952) CRINUM LATIFOLIUM, is figured by Wight, No. 2019 and 2020.

(2953) CRINUM MACROCARPON. Large fruited crinum. There are two gigantic species of crinum indigenous in the low grounds near the sea coast of Tenasserim, one of which is the large fruited crinum, and the other, which is nearly related to it, bears a large bunch of fragrant flowers and has been recently introduced into gardens.—*Mason.*

(2954) CRINUM ORNATUM. ORNAMENTAL CRINUM. There are no lilies in the Tenasserim country, but they are well represented by the crinums, which Europeans usually denominate lilies. A very large petalled species, of which there are two varieties, is much cultivated in gardens, and is quite an interesting plant.—*Mason.*

(2955) CRINUM ASIATICUM, variety *toxicarium.* Sookh durson, Burra kanoor, *Beng.* Poisonbulb. Sookh-dursun, (interview of ease), *Hind.*—*O'Shaughnessy, page* 655. A certain and mild emetic: from two to four drams of the recent root. Dr. Irvine says it is cultivated as a lily in gardens; the flowers are fragrant and ornamental; the juice of the leaves is applied to the meatus auditorius externus in ear-ache; its juice is also emetic, but is very irregular in its action.—*Genl. Med. Top. p.* 138. Syrup of Kanoor is nauseant and emetic for children. Dose, a desert spoonful repeated as required.—*Beng Phar. p.* 411. An Infusion of Kanoor, *Crinum Asiaticum or toxicarium,* is a mild and certain emetic. In doses of two drachms, given every twenty minutes, this solution occasions nausea and perspiration. It does not cause griping, purging, or any other distressing symptoms.—*Beng. Phar. p.* 301.

(2956) CRINUM ZEYLANICUM. CINGALESE CRINUM.

Sookhdursun, HIND.

Grows wild in low grounds near the Chumbul river.—*Gen. Med. Top. p.* 188.

(2957) CROCODILIDÆ, CROCODILE-TRIBE, Crocodiles, a family of Saurians, comprising the largest living forms of that order of Reptiles. Dumeril and others distinguish the family by the appellation of Aspidiot (shielded) saurians, while many modern zoologists have considered them as forming a particular order. They form the *Loricata* of Merrem and Fitzinger, and the *Emydosaurians* of De Blainville.—*Engl. Cyc. page* 916. The Crocodile, Buwaya, *Malay,* Baya, *Javanese,* is found in all the rivers of the Malay and Philippine Archipelagos. The Malays of the peninsula reckon three species, the *labu* or *gourd,* the *kutak* or *frog,* and the *tambaga,* or Copper Crocodile. That found in Sumatra and Java, is the Crocodilus biporcatus of naturalists, which is found also in Celebes and Borneo, and the Moluccas; but in addition to this there is another in the rivers of Borneo, formidable by its size and rapacity, partaking of the character of the biporcatus and the gavial of the Ganges.—*Crawfurd, page* 10.

Gavialis.—The Gavial. Jaws very long, subcylindrical, slender, rather dilated and convex at the end. Teeth, canines two, quite anterior, small; lower canines shutting into a notch in the edge of the upper jaw. Feet fringed; toes webbed to the tip. The cervical plates united to and forming a disc with the dorsal ones. Males with a large swelling in front of the nostrils. Native of Asia.—*Engl. Cyc. p.* 198.

Crocodilus.—Jaws oblong, depressed, tapering, rather dilated at the end. Teeth unequal, lower canines fitting into a notch in the side of the upper jaw. Feet fringed; toes webbed to the tip. Nuchal and cervical plates forming a disc separated from the dorsal one by small granular scales. The head of the newly hatched specimens is short, but it gradually elongates, and after a short time attains the form proper to the species, and, through the bones becoming more solid by increasing age, they only slightly alter the relative proportions of the different parts, so that the form of the head, taken with the shielding of the back, affords good characters for the determination of the species.—*Engl. Cyc. page* 199.

Crocodilus porosus, the Indian Crocodile.

Crocodilus bombifrons, the Large-Headed Indian Crocodile.—*Engl. Cyc. page* 199.

Gavialis Gangeticus, the Narrow-Beaked Crocodile of the Ganges, Edw., 'Phil. Trans.'—*Engl. Cyc. p.* 202. Naturl. Syst. Amph.; *Gavialis Gangeticus,* Gray, 'Syrops Rept.;' the Gavial of the Ganges, Griff., 'Anim. Kingd.'—*Engl. Cyc. p.* 293. The Gavial of the Ganges is supposed to be the largest of the living Saurians. The measurement of the largest mentioned by Messrs. Dumeril and Bibron is given at 5 metres, 40 centimetres (17 feet 8 inches).—*Engl. Cyc. page* 205.

(2958) CROCUS SATIVUS, SAFFRON.

Zaffron, HIND. ARAB. | Kurkoom, PERS.

A native of Asia Minor, naturalized in England, France, and many other parts of Europe, and cultivated in Persia and Cashmere. The saffron of commerce consists of the dried stigmata of the flower. These are picked out, dried on paper either in a kiln or by the sun. If

compressed into cakes it is accordingly called *cake* saffron; *hay* saffron is what is usually met with. The *hay* saffron consists of the stigmas, each about an inch and a half long, brown-red, the upper part flattened, widened, and cleft; the lower, hair-like and yellowish. The odour is fragrant, taste bitter but agreeable. Saffron tinges the saliva yellow. Mr. Pereira informs us that one grain of good saffron contains the stigmata and styles of nine flowers, so that one ounce of saffron is equal to 4,320 flowers. *Cake* saffron as now met with contains none of the real article, being prepared from the florets of the safflower (see *Carthamus*) made into a paste with gum water.—*O'Shaughnessy, p.* 654. Dr. Honigberger, p. 263, mentions that Crocus sativus is monopolized by the Cashmerean government and that the Hakims of the Punjab use saffron in melancholy, typhus fever, enlargement of the liver, and retention of urine.

(2959) CROCUS VERNUS.—This plant never flowers in the Western part of India, the roots when planted only produce leaves, wither and die.—*Riddell.*

(2960) CROSSBILL. There are many who consider the Parrot Crossbill (*Loxia pityopsittacus*) to be merely a larger and more robust variety of the Common Crossbill (*L. curvirostra*). By the same rule, the Himalayan Crossbill (*L. himalayana*) should be regarded as a smaller and considerably less robust variety of the same species; in which case, the amount of variation would indeed be extraordinary, and we should expect to find every intermediate gradation. The Crossbills, in a general way and with unimportant exceptions, may be said to inhabit wherever there are pine-forests; however rare, comparatively, in those of the Himalaya: and they are birds of remarkably vagrant habits, which therefore should not be particularly subject to climatal or local influences, whatever these may be, to induce permanent variation, as manifested by a series of distinct races.

(2961) CROTALARIA. A genus of plants of the family of Leguminosæ, containing several species, all employed for cordage materials. The C. juncea, yields the Sunn of Commerce: the C. tenuifolia, furnishes the Jubbulpore hemp, and C. retusa in Madras and C. Burrhia in Sind, are employed for cordage and canvass, and in fabricating the coarse gunny cloth. Dr. Wight figures fifteen species Crotalaria barbata, 980; bifaria, 30; bracteata, 273; evolvuloides, 31; formosa, 981; lunulata, 480; Notonii, 752; obtecta, 208-383; pulcherrima, 481; rubiginosa, 885; semperflorens, 982; speciosa, 29; trifoliastrum, 421; verrucosa, 200: Wallichiana, 982.

(2962) CROTALARIA ELEGANS. The seeds are contained in inflated pods, which rattle when shaken, grow readily in any tolerably good soil, and abound in this country.—*Riddell.*

(2963) CROTALARIA JUNCEA, Sunn Hemp, called also—Sunnub, Vuckoonar, Shanal or Jute gramee. In the Madras Presidency this plant is largely cultivated for the manufacture of Rope, string and gunny bags. At the Madras Exhibition of 1855, it was exhibited from a great many districts, but every specimen had been more or less discoloured, and its strength impaired by steeping too long. The best sample was exhibited by the Masulipatam Local Committee. This fibre is not so strong as many others, but it is well suited for the manufacture of gunny bags and paper, and is sometimes sold as Jute; The exports from Madras in the year 1850-51 were

Sunn Hemp, ...	cwt. 2,095
Twine from Do., ...	cwt. 1,372
Gunny bags, ...	58,950

Near the Burmese villages large fields of *Crotalaria juncea*, as tall as wheat, may be often seen. Although the stems of the plant produce a substance analagous to flax or hemp, it bears no relation to those plants, but is a species of crotalaria, a leguminous plant. The true hemp, though occasionally grown to a small extent, is never fabricated into cloth.—*Mason.* Its commercial products is the Sana, *Sans.* Sunn, *Hindee.* Ghore Sunn and Meesta pat, *Bengalese.* Kenna, *Cing.* Hemp and Sunn Hemp in Calcutta; Janapa, Shanapum, also Madras Hemp; Taag or Conkanee Hemp, Salsette, and Bombay Hemp. Some of the *Brown Hemp* of commerce. The Sunn is probably the earliest of the distinctly named fibres, inasmuch as we find in the Hindoo 'Institutes of Menu,' that the sacrificial thread of the Kshatriya or Rajpoot is directed to be made of *Sana*; cotton being reserved for the Brahmins. Its name, *Shanapam* or *Janapa*, on the Madras side, is not very unlike *Canapa*, *Hampa*, *Hennip*, and *Hanf.* From these we derive our own name of *Hemp.* Under the name *Sana* it is mentioned in many Sanscrit works; and by that of *Sunn* it is known in most parts of India. The first notices in European works is, by Rheede ('Hort. Mal.,' v. ix, t. 26); by Ironside, in the 'Phil. Trans. of London,' lxiv, p. 99; and it is mentioned by Roxburgh in the early volumes of the Society of Arts' 'Transactions.' Towards the close of the last, and the beginning of this century, it attracted much attention both in India and in England; and much information respecting it is contained in Dr Roxburgh's several works, as well as in Wisset's 'Treatise on Hemp and on the Sunn Plant,' 1804 and 1808. Dr. Buchanan in his 'Journey through Mysore,' mentions that Goni cloth for sacks is made of the fibre of *Crotalaria juncea.* The annual stem is straight, smooth, striated, from four to eight (varieties even ten and twelve) feet high, branching towards the top, but more so when the plant stands single. Leaves scatter-

ed, short petioled, lanceolate, obtuse, with a small bristle-like point, from two to six inches long, both sides covered with soft, silver-coloured hairs. Stipules subulate, small. Flowers in terminal racemes, papilionaceous, of a beautiful bright yellow colour, each supported by an oval bract. Calyx two-lipped; the upper lip two-cleft; the under one two-parted in the middle. Of the yellow petals, the banner is obtuse, erect; the two wings oblong, obtuse; the keel much pointed, slightly twisted at the apex, and closely shut. Filaments ten, their lower half united into one body, with a fissure down the upper side, which has a circular gape at the base; extremities free, and the alternate ones shorter than the others. Anthers on these linear; on the larger filaments ovate and two-lobed. Legumes sessile, club-shaped, turgid, from one to two inches long. Seeds numerous, kidney-shaped. (Roxb., 'Flora Indica,' iii, p 261; 'Corom Pl.,'t. 192.) The seeds when ripe and loosened rattle within the pods, as in the other species, whence the genus has been named from the Greek word *krotalos*. It is an annual plant, very generally cultivated in the Southern parts of Asia, and everywhere in India, on account of the fibres of its bark, so well known as *Sunn* and *Sunn Hemp*, often erroneously called Hemp, though the true hemp plant is also most common in India, but valued in the plains only for its intoxicating properties. The Sunn is exported from different parts of India, as from Calcutta, by the name of Sunn; that from Madras is known in England as Madras Hemp; that from Bombay as Brown Hemp, being known there as *Taag* or Conkanee Hemp; it being a common practice to name it from the province where it has been grown. The late Dr. Stocks informed Dr. Royle that it was cultivated in Sindh, and that the species named *Crotalaria Burrhia*, which grows wild in the most arid places, is also employed in Sindh as a cordage plant. Dr. Royle also mentions that he has seen it thickly sown and carefully cultivated in the most northern provinces in India. The time of flowering and ripening its seed, as stated by Dr. Roxburgh, depend on the season it is sown; though in most parts it is raised during the rainy season, in others it is not sown until their cessation.

Culture.—The general time of cultivation is during the rains; and in Bengal a rather elevated rich soil is required, which ought to be well ploughed, or otherwise dressed to free it of weeds, and bring it into good tilth. In Wisset's treatise, pp. 38 and 39, it is stated that clayey soils are injurious, and that in a rich soil the fibre produced is of a coarser quality than that from high, dry situations. The quantity of seed, Dr. Roxburgh states, should be from eighty to a hundred pounds weight to the acre. In some districts less, in others a larger quantity is sown (*v.* Wisset.) The natives say, the thicker the Sunn grows the better, and so thick as to prevent the air from passing through it. (l. c., p. 73.) At Commercolly it is stated that there are two kinds of Sunn; one being sown in June, the other in October, though they are nearly similar in quality. That sown in June is generally cut about August or September, and the other about April; but it is also sown in October in parts of the Dacca district (*v.* Wisset, pp. 59 and 82. The cause of the difference in the time of cultivation, is supposed by some to be that during the periodical rains the face of the country is under water. In most places the seed is sown when the first showers fall, in May or June, and covered in by the harrow, or by any other mode. Little more is required, as the plant grows so rapidly as to keep down the weeds itself; otherwise it requires to be freed from weeds, when about nine inches high. By August the plant will be in flower, and from five to eight or more feet high. When the fibre is required of a fine and soft quality, it is pulled in this stage of its growth; if greater strength is the object, it must stand till in seed, or even till the seed is ripe. A portion of the crop always requires to be left for the sake of ripening some seed. The natives make use also of the fibres of such plants, and consider them strong. When ready for the purposes intended, the plant is cut or pulled up by the roots. At Hurriaul it is cut down as close to the ground as possible, and laid in ridges, care being taken to place the plants so that the leafy parts be one upon another. In this state they continue five, six, or ten to twelve days, or until the leaves begin to rot and fall from the stalks on being shaken about (l. c., p. 113.)

Produce, &c., per acre.—The produce of the cultivation of this plant per acre is most fully detailed in the abstracts of reports given by Mr. Wisset, and varies from 3 cwt. to 10 cwt. per acre; or on a medium probably about 700 lb. an acre. But there is difficulty in determining the point with exactness, from the difference in the begah as well as in the maund. The cultivation was said to yield tolerable profit, inasmuch as the plant requires scarce any attention, and consequently little labour or expense; and it may be off the ground in time to allow this to be prepared for any cold-season crop. But the expenses and the profit are as variously stated as the produce. The price is also given as varying from R. 1 8, and R. 1 12, to Rs. 3 per maund, at the same time; which it is difficult to account for, except from the habitual carelessness of the natives of India in all such statements. (*v* 'Wisset,' pp. 146—155.)

Steeping.—Having grown and cut the plant, as well as removed its leaves, it is ready for the next process, that of committing to water, or other operation for separating its fibre. The length of time required for steeping depends on the season of the year, the heat of the weather, and consequently of the water. In

August and September, from two to three days is generally sufficient. When the required effect has been attained, which will generally be known by the bark separating freely from the stalk, the people employed in the work stand in the water in which the plant has been steeped; each takes a handful thereof, which he breaks in one or more places, after having washed off any mud or filth; then grasps it by one end between both hands, and beats it against the surface of the water, which quickly removes the reed from the fibres; after which the parcel is turned, and the other end treated in the same manner. Care must be taken not to over-steep, as this much weakens the fibre. (Wisset and Roxburgh.) With respect to the proper time for steeping, and the period during which the stems should be steeped, great differences of opinion prevailed during the experiments at the beginning of this century. Mr. Fleming, disapproving of the native method of steeping the plants immediately after they were cut, and for three or four days, recommended that the plants, after pulling, be *first dried in the sun for two days*; after which, they should not be let to remain in the water more than *forty* hours. Mr. Frushard objected, first, to the drying the article before watering; secondly, to the insufficiency of the time for watering; and lastly, to the manner of separating the fibre from the reed after watering. The general practice, he observes, is to set the plant upright in the water, immersed about one third only from the bottom, for one day before the complete immersion, in order that the thicker may be immersed longer than the thinner parts. Of the natives one said, "to dry before steeping was doing to undo." Another observed that it seemed to be "wanted to make difficult what was easy." Others exclaimed: "You may imprison our persons; you may strike our necks; but never will we make Sunn according to the advertisement." (*v.* Wisset, pp. 162, 195, and 202.) The whole forms an interesting commentary on attempts to improve native processes, before principles are thoroughly understood, or the superiority of European practices carefully established. At Commercolly, when the plants of *Phool Sun* have been pulled and tied in bundles, they are for a day or two kept standing on their roots in an inch or two of water, which allows the fibre to obtain a proper degree of firmness, without suffering it to be parched by the heat of the sun. Dr. Roxburgh observes, "all that seems necessary is to caution the cultivators against oversteeping the plant, which they are apt to do, because it renders the separation of the bark from the stalks easier, but weakens its fibres. Small pools of clear water, well exposed to the sun's beams, seem best suited for steeping in, because heat hastens maceration, consequently preserves the strength of the fibres, while the clean water preserves their colour. Deep water, being cooler, requires more time for the operation." He further states, that the result of many experiments leads him to think that steeping immediately after the plant is pulled is the best, at least in Bengal during the rains, for then it is very difficult to dry it, and the fibre becomes weakened and the colour injured. He found no advantage, but the reverse, by drying the plant, after maceration, and before the bark was removed, as often practised with Hemp and Flax in Europe. But in his 'Fl. Ind.,' iii, p. 262, he says: "Others, and I believe with good reason, recommend its being dried for some time previous to its being steeped." When the seed is ripe the fibre is stronger, but requires a much longer time for steeping. If the Sunn be dressed before it is shipped for England, the commodity will be rendered more valuable; but considerable loss of weight (probably about one third) having ensued from the combing or heckling removing much short fibre or tow, it is of course increased in price. The Sunn of Bengal is always whiter than that of Bombay, owing to the mode in which it is prepared.

Drying.—When the Sunn has been thoroughly washed, it is usually hung up on lines or bamboos to dry. When dry, it is combed, if intended for fishing nets or small lines; but if for common use, they merely separate the fibres a little with their fingers, and make it up into bundles for market. The use of the Hemp-brake is unknown in India, but the Sunn might in many cases, after watering, be bruised with a brake and then scutched. It is in cleaning the fibres Mr. Frushard considers that the natives are most liable to fail. He thinks it ought to be strongly insisted that they beat the plant (by handfuls at a time) on the surface of river water, in order to get rid more readily of the filth and mucus with which it abounds after steeping. But when the fibre is separated it must be thoroughly washed, by repeatedly squeezing the water out of it, and ultimately well wrung, to accelerate the essential process of careful drying. The cylinders for pressing Flax when moist would be useful, as also scutching mills properly suited to the fibres to be separated and prepared. After the fibrous parts are well separated and well washed, they are in some places in Bengal laid in the sun to dry, before stripping them. At Jungypore, after washing and beating in the water, the *Sunn* is exposed to the rays of the sun for an hour or two, and the stalks are separated when half dried. Mr. Fleming recommended that, after watering the plants forty hours, they should be taken out and dried gently in the sun for three or four hours, before the fibres are separated. The natives, say, that to dry the plant on taking it out of the water before separating the fibre from the seed, will occasion a much greater loss in tow; so

that they never practise this method except when distressed for time, and under the dread of leaving it too long in the water, when any parcel proves too much for the labourers employed in one day. Mr. Frushard also objected, that such drying must be insufficient, saying that in Europe, generally, the plant is most thoroughly dried before it is put under the brakes, and that in Livonia the Hemp is heaped up, and covered up with straw, &c., in order to make it *sweat*, and that the Livonians say, it is in this operation of *sweating* that the good or bad quality of their Hemp depends. Mr. Frushard observes, that "the natives get through the whole business with so much celerity that their mode of practice is highly in favour of the fibre retaining its strength; and should *sweating* be found to answer, it will be found much more congenial to its execution than the doing it while the fibre is still on the reed." The measures adopted were successful to a great extent. Though the natives did not adopt all the innovations which had been proposed to them, yet from the supervision practised, they prepared the Sunn carefully, according to their own methods, and that of itself was a great advantage; as only the good specimens were purchased by the commercial agents.

Strength of sunn fibre.—In an anonymous pamphlet entitled, 'Observations on the Sunn Hemp of Bengal,' 1806, it is stated, that "the Court of Directors having sent orders to Bengal for the cultivation of Sunn with increased attention, tolerable success was attained in most places, but a superiority has certainly been manifested in particular spots, such as Dacca, Luckipore, Chittagong, Hurriall, Malda, Budaul, Rungpore, Radnagore, and Soonamooky;"—but Commercolly and Cuttorah are not particularised, though good Sunn was no doubt produced at both places. These places have been mentioned now, to show that the experiments were carried on chiefly in Bengal, though it is by no means proved that the soil and climate of that province are better suited than those of many other parts of India for the production of good fibre. Indeed, there is little doubt that, whether owing to differences of soil and climate, or of preparation, the fibre of the same plant as grown in the West of India is stronger than as grown in Bengal. In the anonymous "Observations" it is further stated that "the culture has not only been attended to by the most scientific men in India, but the means of dressing it so as to preserve the greatest strength to the fibre, &c.; and it is satisfactory to state, that some of the Sunn has exhibited a very considerable proportion of strength beyond the common expectation." The above pamphlet is however chiefly valuable for giving the results of various "Experiments, made from 1802 to 1806, to ascertain the comparative strength of Sunn with Russian Hemp," made at Messrs. Huddart's rope-manufactory. But in order to ascertain its comparative merit therewith, it is necessary first to state, that the difference in strength between the best and ordinary Russian Hemp is in the proportion of 5 to 4, sometimes as 6 to 4: that the strength of the best Russian Hemp to the best Sunn bears a proportion as 6 to 4." (p. 5.) "From hence it must be admitted, the Sunn, manufactured in the usual mode for the cordage, cannot be put in competition for strength with Russian Hemp;" but when prepared by Huddart's Warm Register, "the proportion between Sunn so manufactured and the best cordage made in the common mode, when above six-inch, is in favor of the Sunn cordage, progressively as the size is increased." Instances are then given of "a sixteen-inch cable made from Sunn in 1802, laid down as a mooring cable at Gravesend the whole winter; and after various examinations, by cutting off the clinches, upon different ships taking it in as moorings, for five months in succession, it was found so fresh and good, that it went by the last ship that rode by it, to India, as a working cable." (p. 6.) It was also made into canvas and other cloth with success. "This has been manifested in a topsail made for one of the Indiamen, put on board here without any intimation of its difference; and the sail is returned not worse than the other sails of the ship." (p. 7.) Its weft only was Sunn, the warp Flax. But it must be remembered that these experiments were made with the Sunn which had been grown and carefully prepared under the supervision of the East India Company's commercial agents. A specimen of one of these *Sunns* is stillin the India House, marked per *David Scott*, 1802; which, though having the light colour and showing the appearance of ordinary Sunn, is from four to five feet in length, much cleaner, both strong and flexible, and also divisible into fine fibrils. A salvage of it bore 175 lb., when some Sunn sent to the Exhibition of 1851 bore only 150 lb. There is a specimen also of the heckled Sunn, per *Wellesley*, 1802, about three feet long, a bright-looking fibre, but with a good deal of the cellular part still adhering to the fibres. Ordinary Sunn is, moreover, only about three feet in length, rather dirty; fibres entangled and intermixed with portions of the boon, as well as with many short fibres; hence much loss is sustained in heckling, and the men complain of the irritating particles which are given off during this process. The want of strength is not surprising, for, though three days is thought sufficient for the steeping, we learn that the natives, from the press of other work or from indolence, sometimes allow the stems to remain in steep for fifteen days. (*v.* Wisset, p. 195.) It has already been mentioned that Dr. Roxburgh, in heckling, found it lost about one third; though the tow is of course of use for some purposes. But that some good Sunn is also prepared in the present day is evident from

the difference in price which it brings in the English market. Mr. Dickson also having passed some of it through his machine, the Sunn has become light-coloured and clean, with the fibres lying parallel to one another, and showing them as well fitted for spinning. Parties who have seen it have pronounced it well worth £35 a ton. That good Sunn may also be produced in some of the old localities is evident, for Mr. Seonce, when Collector of Chittagong, having grown some Hemp and Flax in this district, grew also some Sunn, which was thus reported on by the Hemp and Flax Committee of the Agri-Horticultural Society, 1843. "G. *Sample of Sunn* (*Crotalaria juncea*) *or Indian Hemp.*—Quality in every respect superior; clean, strong, of even fibre; would meet with an extensive and ready sale in Europe; it would pay better if not heckled" but merely scutched. "In addition to the above, your Committee would beg to call the attention of the Society to the memorandum appended to this Report, obligingly furnished by Mr. Deneef." "G. This is also a good-quality sample; but, like samples B and E (dressed Hemp and dressed Flax), it has been prepared in too expensive a manner to admit of its being profitable. It is much better than my sample of Sunn, and perhaps would fetch £20 per ton in the English market." The sample of true Hemp grown at Chittagong, Mr. Deneef says, would have fetched £18, but if better prepared, £25 per ton.

Culture in Madras Territories.—Dr. Roxburgh, in describing the culture about Rajahmundry, and in the Northern Circars, states that the seed is sown towards the close of the rains, in October or November. A strong clayey soil suits it best, the farmers say. About 120 lb. of seed to the acre is the usual allowance. It requires no further care than being covered with the soil, which is done with the common Hindoo harrow. In February or March soon after the flowers drop, and before the seeds are ripe (when the Telinga people consider the fibre to be in the greatest perfection), it is pulled up by the roots, like Hemp in Europe; half dried in the sun, then tied up in bundles, and committed to the water, where it is steeped, &c. This plant, he further mentions—it is the only one—is also cultivated there by some natives to feed their milch cows with during the dry season. It is very nourishing, and causes them to give more milk than most other food. It only bears two or three cuttings; after that, the plants perish. ('Corom. Plants,' v. ii, t. 193.) Sunn is also cultivated in Rajahmundry as a second crop, on wet lands, with profit to the ryot; and is even exported from that and other Northern districts in some quantity. Dr. Buchanan, in his 'Journey through Mysore,' mentions that, at Bangalore, Goni is a considerable article of manufacture, and that it is a coarse, but very strong sackcloth, from eighteen

CROTALARIA JUNCEA: SUNN.

to twenty-two cubits in length, and from a half to a quarter of a cubit broad, and that it is made from the *Janupa*, or *Crotalaria juncea*. The *Goni* maker hires from some farmer as much high ground as he thinks will raise a quantity of *Janupa* sufficient to employ his family in manufacturing for the year. The soil may be red or black, but is not manured. The seed is sown broadcast when the rains become heavy. But it is also cultivated on rice-ground in the dry season, with the aid of irrigation. It requires four months to ripen. When cut down it is spread out to the sun and dried. The seed is then beaten out by striking the pods with a stick. The stems are then tied up in large bundles, and preserved in stacks or under sheds. The bundles are taken out as wanted, and put in the water, at which time their bands are cut, and the stems, being opened out, are kept down to the bottom by stones or mud. According to circumstances, they require to be kept in the water from six to eight days. When the bark separates easily from the stems they are taken out of the water, and a man taking them by handfuls beats them on the ground, and occasionally washes them, until they are clean, and at the same time picks out with his hand the remainder of the boon, until nothing except the bark be left. This is then dried, and, being taken up by handfuls, is beaten with a stick to separate and clean the fibres. ('Journ..' i, p. 226.) But when at Bhawani Kudal, in the Coimbatore district, he found a great deal of the *Shanapu*. This was grown by the farmers, who, when it is fit for steeping, sell it to the people called Telinga Chitties, who make the Hemp, and work it up into *goni* or sackcloth. There it thrives best on a poor, sandy soil, which, however, is manured any day between the 12th of July and the same day of August. The seed is sown broadcast after rain, and very thick—rather more than two bushels for an acre. The stems are sold by the thousand handfuls. Tall plants sell at two rupees for the thousand handfuls; short ones for a rupee and a half. But the same plant is also cultivated on fields that have produced a crop of rice, between the 12th of January and the 12th of February. In the following month the field is watered, the seed sown, and covered with the plough. Once a month it requires to be watered, and it takes four months to ripen. This is more valuable than the Hemp cultivated on dry field. An acre requires $4\frac{8}{10}$ bushels of seed, and its produce was in those days worth about £1 2*s*. $10\frac{1}{2}$*d*. Of these two notices the first is interesting, as showing that the natives of Mysore adopt a practice, that of drying their Sunn stems, which is objected to by those of Bengal: the second showing a separation of the occupations of growing and of preparing the fibre; and this may, perhaps, with a congenial climate, account for the goodness of the fibre of

the Western coast. Dr. Wight states that on the Madras side of India, not only the bark of this species, but of *Crotalaria retusa* is employed as Hemp in the manufacture of cordage and canvas. He further found the Janapa or Sunn plant cultivated at Coimbatore. The stems, cut and dried, were afterwards steeped. This loosens the bark, which is then easily stripped off, and undergoes but little further preparation. He found its fibres were next in strength to the *yerkum* or *mudar*, sustaining 407 lb., when the latter bore 552 lb., and has since observed to Dr. Royle that the *Sunn*, grown in the Pass of Poonany, open to both monsoons, is stronger than that grown in the interior. Dr. Hunter has given the following account of the preparation of such fibres near Madras: "The native process of cleaning plants having bark and woody fibres"—of which kind are many of the cordage plants--" is very similar to that followed in cleaning fleshy and pulpy plants, viz., by burying in sand or mud at the edge of a tank or in a river, and leaving them to rot. There is this difference, however, that the plants are steeped longer, and are never exposed to the sun to dry, or stacked and covered with matting to be cleaned by dry beating. If this were done, the woody fibre would get hard and brittle, and would again adhere to the other fibre, which being partially rotten would break in the cleaning. To obviate this the rotted plant is taken up in large handfuls, and beaten on flat stones, first at one end and then at the other, in the same way as clothes are washed by the Dhobee; they are next well rubbed and washed to separate the impurities, and are spread out on the ground to dry. We can hardly wonder that most of the string and rope made from fibres prepared in this rude, coarse way, should be dark in colour, possessed of no strength, and of little value. As a general rule, every day's steeping of a fibre takes from its strength and imparts more or less colour. To obviate this, woody plants should be first well beaten with a mallet; then the bark should be separated from the stalk, for it is on the inner part of the bark that the fibres for cordage usually occur. When the bark is brought to a pulpy state, it must be well washed in clean water to remove as much of the sap as possible; for this is the distructive agent which soon causes putrefaction."

Culture in the West of India.—On the Bombay side *Sunn* is also extensively cultivated, and attracted some attention at the beginning of this century in the island of Salsette, whence it was called Salsette Hemp, which is probably the same substance now called Brown Hemp. On that side of India, Dr. Roxburgh says, as in some other parts of India, the seed is sown towards the close of the rains, when a stronger soil is said to be required. We have seen that Colonel Sykes enumerates the Sunn among the spring crops; that is, among those sown in autumn and reaped in spring. This Bombay Hemp or Sunn has always been highly esteemed. Dr. Roxburgh says it is reckoned particularly good—not inferior to the best Russian Hemp ('Fl. Ind.,' iii, p. 263); which he conceives is due to the mode of preparation, which we shall immediately notice. But something must also be owing to climate. So long ago as the year 1802, some fibre was imported by Capt. Isaacke, of the *Skelton Castle*, which was at first considered to be the real Hemp, and called *Malabar Hemp*. Capt. Eastwick, one of the Directors of the East India Company has informed Dr. Royle that Major J. D. Watson also paid great attention at this period to Malabar Hemp. Dr. H. Scott writes of it, that he does not know whether it be the same plant as the *Sunn* of Bengal, but where very great strength is necessary, the substance obtained from it is preferred to the Bengal Sunn, and is very superior to anything of the kind he has seen in the Guzerat. This, he thinks, may depend more on the steeping of the plant and the preparation, than on any difference in the vegetables that produce it; and this opinion was proved to be correct, for Dr. Roxburgh, having obtained some of the seed, found it to be *Crotalaria juncea*. It was about the time that Dr. Roxburgh was employed in the culture of fibres in Bengal, he learnt that in the island of Salsette, where the best Sunn is said to be prepared, little or no maceration is employed; that the plant while moist, is peeled by the hand, and immediately dried in the open air or under cover, according to the state of the weather. By peeling, the fibres are better kept in their natural state of arrangement, and give support and strength to each other; whereas, by the process of the Bengalese, they get so materially entangled, that a great loss is always sustained. If they are restored to their natural situation by the heckle, there is a loss of nearly one half of the original quantity, which renders the heckled Sunn of Bengal of a high price. Dr. Roxburgh further says, in 'Fl. Ind.,' p. 283: "Numerous experiments made by me induce a belief that the superiority of the Hemp depends upon the peeling; but it is probable that the climate of the West of India may be more favourable than that of Bengal for the production of a stronger fibre. For no great attention seems to be paid to the culture, according to recent accounts." More recently, Capt. Thompson, of the firm of Thompson and Co., rope-makers, of Calcutta, in sending three samples of fibre from the Malabar coast, writes: "Allow me also to hand you three specimens of Hemp and rope made of them that I had brought from the west side of India, grown at the places named on the labels (Calicut, Ghote, and the Concan). These have been tested both at the Arsenal and Government Dockyards, and proved perfectly equal to any and

CROTALARIA JUNCEA : SUNN.

all purposes that cordage made of Russian Hemp has hitherto been used for. From the encouraging reports upon this cordage from the heads of both the Naval and Military Departments, there seems no reason to doubt that this Hemp, and others that are being daily discovered, will completely supersede the importation of Europe-made cordage." Capt. Thompson adds, in a note: "This Hemp is no new discovery. I saw it in England, which led me to try it here (*i. e.*, Calcutta), 31st Dec., 1847." Dr. Gibson, in a Report on the Agriculture and Horticulture of the districts near Bombay, states, that both the *taag* and *umbaree*, or *Crotalaria juncea* and *Hibiscus cannabinus*, are both reaped in the month of November, and both are stored to await the advent and leisure of the warm weather for stripping. The Tag is most usually pulled up, instead of being cut off; as in the latter way it leaves a strong and dangerous stubble. It is in the Deccan, he adds, reckoned a species of cultivation unworthy of a thorough-bred husbandman, and only to be grown by the Ghaut people and the wilder tribes. The Wunjaras not unfrequently hire land to grow it on, as it is essential for affording them twine and materials for their gunnies. The seeds are beaten out with a stick, a part is reserved for future sowing, and the overplus is used to feed buffaloes. Its cultivation is more attended to in the Concan and Ghat districts than in the Deccan. It appears to suit any soil, and clears the ground of weeds. Having cultivated the plant to some extent in 1841, he found that it gave a return quite equal, if not superior, to that of the common grains of the country. Its chief expense consists in stripping the fibre. He had tried to separate the fibre by beating, after a slight immersion, but found the interior pith too soft to admit the separation of the fibre by that means. It is first steeped in water for five days —in running water—and the fibre is afterwards separated by the fingers. It is used by the natives for articles requiring much strength, as fishing nets, &c. (Agric. and Hortic. Soc. of Western Indian, 1842.) Some specimens of the fibre of the *taag*, or *Crotalaria juncea*, having been sent to England to be reported on, were spoken of in the following terms, though the name of the reporter at Hull is not given (1840): "This sample, No. 2 (*Crotalaria juncea* or *tag*), appears to me of the same quality as the Baltic. I return a part of it, made ready for spinning. You will see the great similarity of the two. My wine-spinner assures me that by taking it sooner, and by using more care in the steeping and exposure, it will be *fully equal to the Baltic*. Surely, by attention, this may be accomplished. It may require Englishmen to direct, and our implements (which are truly simple) to be used —when I have no doubt of the successful result, alike to the grower, the merchant, and our country. Your Hemp is very clean—a material point,—but it wants more beating and dressing; and I think the natives have not proper implements to do it with. You cannot improve in your mode of packing; it is decidedly superior to the Baltic. I do not despair of seeing the produce of the Baltic supplanted by that of India; as the defect appears to me solely to arise in the management of it: it stands too long before it is pulled or cut, or is too much steeped or exposed, to get the fibre to separate from the stalk." (Agric. and Hortic. Soc. of Western India, 1842.)

Wuckoo nar (or fibre), or *Travancore Flax*, as it has been proposed to be called, is another instance of the effects of locality and of climate, combined with variations in the mode of preparation, in making it impossible, from the appearance of fibres, to know the plants producing them. To the Exhibition of 1851, some specimens of strong canvas were sent from Travancore, which have been much approved of by competent judges, from the compactness and strength of the manufacture. On trial, it was found that a piece of this canvas, containing *eleven* threads, was equal in strength to canvas containing *fourteen* threads of Polish rein. Along with the canvas, a few small heads of the fibre were sent, and labelled *Wuckoo* and *Wucknoo nar*, or fibre, from Travancore. The appearance of this fibre is totally different from any other which comes from India; as it is in the state as if prepared for spinning into thread, and must have been combed or heckled. The fibres are brownish in colour, about 3 to 4 feet in length, clean, and shining, not so fine as Flax, but still resembling some of the coarser kinds. A very competent judge informed the Author that it might be sold for the purposes of Flax, or as a kind of flax, and was worth £35 a ton. So, some specimens sent to Dundee were valued at the same sum, and it was said could be used for the same purposes as Flax, though rather too dry. As the Wuckoo nar was so highly thought of, and the Author was unable to form any opinion respecting the plant which produced it, he requested his friend, Dr. Wight, so well acquainted with the Botany of the Peninsula, to ascertain the botanical name of the Wuckoo plant. The more so, as Travancore, with Cochin as a harbour which large ships can enter, is a favourable locality for the export of an article which seems a very desirable object of commerce. Dr. Wight having written to friends in the locality to ascertain this point, was surprised on hearing, as was the Author on being informed, that the Wuckoo plant of Travancore was nothing but the Tagg of the Western ghauts, and which further north yields the so well-known Brown Hemp of Bombay. Dr. Royle mentions as a curious confirmation of the result obtained, that specimens of the Brown Hemp, passed

through Mr. Dickson's machine, are exactly like the fibres of the Wuckoo nar, as sent from Travancore. The whole subject forms a striking confirmation of the importance of what Dr. Royle has frequently endeavoured to impress upon planters and experimentalists, that is, the effects of climate and of physical agents on the products of plants. As these will be found to be quite as important as seed from particular localities, or the adoption of methods of culture which may be suitable to one and not to another locality where it is attempted to introduce them.

Sunn of N. W. Provinces of India.—Besides Bengal, Madras, and the West of India, Sunn, that is, *Crotalaria juncea*, is also extensively cultivated in North-West India, for ordinary use. The cultivation may be much increased, and it is probable with considerable addition to the strength and flexibility of the fibre, by the aid of irrigation; and this is easily managed in some, and will be so in most places, when the great Ganges Canal is in active operation. It will be found there, as elsewhere, that, as stated by Mr. Deneef as his declared opinion, nothing is wanted but an improved preparation to make it a desirable article for the English market. Enough has been said respecting the value of common Sunn for most of the ordinary purposes of cordage, and also of the invaluable properties of the fibre of the same plant as grown in the Western ghauts, and where its culture may be indefinitely extended, and easily exported by sea. Though some recent Sunn broke with 150 lb., and some old Sunn bore 170 lb., when Petersburgh broke with 160 lb., the two former may not be able to bear the same degree of twisting as the latter, but Brown Hemp has, by competent judges, been considered equal to many of the purposes of Petersburgh Hemp; and the Wuckoo nar bore 175 lb. in the same experiments. Dr. Roxburgh made and published a very valuable set of experiments on Sunn, as grown in Bengal. In Dr. Wight's recent experiments, the Janapa or Sunn bore 407 lb., and Cotton ropes 346 lb.; but the Ambaree or *Hibiscus cannabinus*, 290 lb., and Coir, 224 lb. The Janapa, or Madras Hemp, as it is called in the markets here, is thus mentioned by Mr. Dickson, as already quoted. *Prices* "Madras Hemp, valued when imported at £24 per ton, 2 cwt. 3 qrs. 3. lb.

"This Hemp, when prepared with the Patent Liquid, became soft, white, and so fine when heckled, as to bear the closest comparison with the Flax at £80 per ton. It is better than any Russian Flax for fine spinning. "Bombay Hemp, rough and dark, and valued at £20 per ton: "This article, being similarly prepared, was considered equal in value with the Madras Hemp." Though the importation of Sunn into England, for a time diminished, it has again, during the last ten or twelve years, been imported in increasing quantities; and though there it is avowedly used only for ordinary purposes, Mr. J. Kyd, ship-builder, of Kidderpore, near Calcutta, maintained that the Sunn, if properly cured and dressed, would prove equal to Russian Hemp, and even as it was then produced, it was little inferior to it. All that he considered was required to bring this Hemp to a state of perfection, was European superintendence in the growth and manufacture of the material. The natives, moreover, who have many good fibres within their reach, usually make use of Sunn twine, well tanned with the bark of a species of Rhizophora. The prices of these fibres in the interior, are stated to be from R. 1 8 to Rs. 2 8 per bazar maund; that is, from 3*s.* to 5*s.* for a maund of 84 lb., which is just three fourths of a hundred-weight. So, in the Madras territories, it is stated that these fibres may be obtained at 2*s.* a maund in the interior. In Calcutta, Sunn is quoted at about Rs. 5 per maund; and in Bombay at Rs. 4 8 to Rs. 5½ per cwt. in Oct., to Rs. 8 per cwt. in June, but at Rs. 11 in June, 1854. In the year 1844, when Petersburgh Hemp was selling in England, for £38 per ton, Indian Brown Hemp was sold for £20, Sunn from £16 to £18, and Jute from £10 to £12. In Dec., 1854, Bombay Hemp was quoted at £35 to £48, Sunn £27 to £33, Jute £21 to £25, in the same 'Price Current,' when Petersburgh Hemp was selling at £58 to £64.

Royle's Fibrous Plants, pages 270 *to* 289.

(2964) CROTALARIA OCCULTA. The Pea-violet grows very common by the road-side between Churra and the Eastern Khassia hills and smelt deliciously of violets: the English name suggests the appearance of the flower, for which and for its fragrance it is well worth cultivation. Hooker.—*Him. Jour. Vol.* II. *page* 309.

(2965) CROTALARIA TENUIFOLIA, Roxb. JUBBULPORE HEMP.—*Crotalaria tenuifolia* is a native of Coromandel: perennial, ramous, straight, furrowed, hoary. Leaves linear, sericeous underneath. Stipules minute, subulate. Racemes terminal. Legumes sessile, clavate, many-seeded. In the Botanic Garden (Calcutta) it is perennial, growing to the height of nine feet, with numerous, slender, furrowed, straight branches, which are again more ramous at the top. During the cool season, each twig ends in a long raceme of large, yellow flowers, and seed ripens in two months. Among the cordage sent to the Great Exhibition of 1851, there were some specimens sent by Messrs. Harton and Co., ropemakers, of Calcutta. These appeared to be of excellent quality, and were said to be made of Jubbulpore Hemp. The first notice which we have of this substance is in the 'Proceedings of the Agri-Horticultural Society,' where some Hemp grown in the Jubbulpore Garden from country seed sown at the end of June, 1840, and cut in October, and of canvas woven from the fibre in the School of Industry at Jubbulpore were presented to the Society by Dr. F. M'Leod. When Mr. Williams, Superintendent of the

above School, and by whom the plant had been grown and the fibre prepared, visited England in the summer of 1853, he presented Dr. Royle with a specimen of this fibre. This was long, that is, upwards of five feet in length, of the colour of Petersburgh Hemp, rather roughly prepared, inasmuch as some of the bast is still in the form of narrow ribands, but most of it separated into fine and strong fibres. In the experiments which Dr. Royle had made with it, its strength was proved to be at least equal, if not superior, to that of Russian Hemp, inasmuch as when a selvage of Petersburgh Hemp broke with 160lb., one of Jubbulpore Hemp did not break with less than 190lb. When examined by experienced brokers and manufacturers, it was considered an excellent substitute for Russian Hemp, and if a little more carefully prepared would leave hardly anything more to be desired, and was valued as worth at from £30 to £35 a ton, that is before any rise took place in the price of fibres. The plant yielding this fibre having been discovered, we have given above a description by Dr. Roxburgh, and though some botanists unite it with *Crotalaria juncea*, we keep it separate, until its identity has been determined by experiment. We also add the first notice of this fibre, and of rope made from it. In the 'Proceedings of the Agri-Horticultural Society' for April, 1851, we find Captain Thompson presenting some dressed samples of the fibre from Jubbulpore, and a piece of rope made of it, part of the rigging made for some ships that were dismantled in the Bay of Bengal the year before, and which has proved equal to any Europe-made rope. A good account of this fibre and its uses having appeared in the 'Journ. of the Agri-Hortic. Society,' and referring to the plant producing it, we here subjoin extracts from the paper. At a meeting of the Agricultural and Horticultural Society of India, held on the 12th June, 1852, Messrs. Harton and Co. submitted specimens of the Jubbulpore Hemp fibre in a raw state; as also of fishing lines and tarred rigging made from it. A quantity of this raw material, procured from Jubbulpore by Messrs. Harton and Co. and the late Capt. Thompson about three years ago, was considered so well adapted for cordage purposes, owing to its excellent quality and great strength, that they have been willing to pay a high price for it, to meet the heavy cost entailed by the transport of so bulky an article from Jubbulpore to Calcutta. In consequence of an impression on their part, that the fibre in question was the produce of *Cannabis sativa*—it being so similar in many respects to Russian Hemp—the subject was deemed by the Society deserving of further inquiry. An application was accordingly made to Mr. Williams, Superintendent of the School of Industry at Jubbulpore, for a small quantity of seed, which was sown immediately on its receipt on the 23rd of June,

1852, in the Society's garden. In the course of nine weeks the seedlings had attained the height of 8½ feet, *without branching*—an important point in a fibrous-yielding plant—and commenced flowering in three months from the date of sowing. Dr. Falconer, to whom a specimen was referred, has pronounced it to be the *Crotalaria tenuifolia* of Roxburgh, which Wight and Arnott, and some other botanists, regard as merely a variety of *C. juncea*, the plant affording the well-known "Sunn Hemp" of commerce. But their opinion, it may be observed, is founded on dried specimens. The habit differs very much from that of *C. juncea*. Messrs. W. H. Harton and Co. have been kind enough to furnish the following memorandum regarding the above fibre: "This material has been tested several times in the Government Service, both Military and Marine, and some ropes have been found equal to the staple cordage of Europe. A coil of bolt rope, manufactured by us from Jubbulpore Hemp, tested last year in the Marine Department, broke with a strain of 57 cwt. A coil of the same size, taken from one of H.M.'s vessels, was tested shortly after, and broke with a strain of 59 cwt. It may be observed, that the Hemp used in the Naval yards of the British Government, is all selected from the fleet of hemp-laden vessels, before any is permitted to be delivered to private parties. This Jubbulpore Hemp can no doubt be considerably improved, were the preparing process in the hands of Europeans, manufactured according to the Russian method, instead of being left, as at present, so entirely to the careless and ignorant natives." The following extract from Mr. Williams's letter, dated Jubbulpore, the 19th Nov., 1852, will close this brief notice of a fibre, which, no doubt, will be better appreciated when its merits become more generally known: "I am pleased to learn that the seed of the 'Jubbulpore Hemp,' sent down by me in June last, has germinated so well in Calcutta. I can only grow it to advantage here along the ridges of the neighbouring hills (where it attains the height of from six to seven feet); that grown in the plains turning out weak in fibre when made into Hemp. I have lost considerably by sending this Hemp down to Calcutta for sale, having had the misfortune to have had several boats burnt while going down the river; and the steamers decline taking a cargo of it, in consequence of its combustible nature. The native insurance offices at Mirzapore also object to insure it, except at such high rates as to prevent all chance of profit; so that if it could be cultivated along the banks of the river, I have no doubt but that in a few years it would turn out a profitable source of export." A copy of the official Report on the Experiments made in the Arsenal of Fort William having been subsequently published, is here subjoined.

Report of several kinds of Rope, the manufacture of Messrs. W. H. Harton and Co., of Calcutta, tested in the Arsenal of Fort William, 3d June, 1853.

Kind and quality of Rope.	Size.	Government proof.	Breaking weight.

(Sd.) J. Wilkins, *Offig. Prin. Conductor*, Rear Godowns. Some of the properties of this fibre may no doubt be due to the peculiar characteristics of the plant; but a good deal is no doubt also due to the soil and climate in which it is grown, and something probably to its having been grown and prepared under Mr. Williams's personal superintendence. This is obvious from the fact, stated by Mr. Williams, that he was only able to grow it on the sides of the hills; that grown in the plains below, he observes, was weaker in the fibre. Mr. Henley having grown some of this plant from the seed sent from Jubbulpore, has observed to the Author, that, when grown in the lower provinces, although it attains a great height and grows luxuriantly, it is weaker in fibre and the produce smaller in quantity than when grown higher up the country. The following reports have been made of this fibre by practical men: "The Jubbulpore Hemp is a very strong article, and would take well if it could be sold cheap enough. A considerable quantity could be sold in Dundee." In another note it is stated to be "of considerable value, and that a good price could be got both for it and for good Sunn, valued at £30 and £35 a ton." Some of it sold, in the summer of 1853, for £27 a ton; when it was said to be worth £30 a ton, if a little better prepared.—*Royle's Fibrous plants, p.* 290.

(2966) CROTON, a genus of Plants belonging to the natural order *Euphorbiaceæ*.—*Eng. Cyc. p.* 211. Dr. Wight figures Croton Aromaticum, 1915; lacciferum, 1915; muricatum, 1886; polyandrum, 1885; Tiglium, 1914; and umbellatum, 1874.

(2967) CROTON. WILD CROTON. A species of croton, whose roots are used by the natives for a cathartic, abounds in some parts, especially on the Maulmein hills. This species is not described in Roxburgh.—*Mason.*

(2968) CROTON. RANGOON CROTON. The natives describe another species of croton, common in the neighbourhood of Rangoon, and occasionally found in the Provinces, which is a shrub, three or four feet high, with properties similar to the preceding—*Mason.*

(2969) CROTON CASCARILLA. CASCARILLA BARK. Cortex eleutherii. This plant grows in Bahama, Saint Domingo, Brazil. Aromatic Peruvian bark is met with in short, solid fragments, thin, very hard, brittle, of resinous brown fracture, with an ash-gray, or whitish epidermis; odour aromatic and agreeable; taste aromatic, hot, acrid, and bitter. It is an important tonic and febrifuge, and is used with much advantage in intermittent fevers. It is procured from America.—*Faulkner*. The cascarilla bark is used with decided benefit in intermittents, and in all fevers during the collapse or typhoid state—*dose* 10 grs. to 1 dr. It is burned as a perfume. Cascarilla is imported from America, especially from Paraguay,—*O'Shaughnessy*, *p.* 552 and 553.

(2970) CROTON LACCIFERUM. Aleuritis laccifera, Willd. Trunk arborescent, with rude and angular branches.—*O'Shaughnessy*, *p.* 553. Leaves ovate, downy, serrulated, stalked; calyxes downy; flowers in terminal spikes; fruits small and velvety. This species is native of the East Indies, and is said to furnish the finest of all the sorts of lac, but scarcely ever to find its way to England. It is very pure, of a bright red, and furnishes a brilliant varnish in Ceylon.—*Eng. Cyc. p.* 212.

(2971) CROTON OIL: NAPAULAH OIL. Oil of CROTON TIGLIUM.

Neervalum yennai, TAM.	Jumalgotay-ka-Tel, HIND.
Naypalum vittiloo, TEL.	Tiglii oleum, LAT.

Is prepared by grinding Croton seed, placing the powder in bags, and pressing between plates of iron; the oil thus expressed should be allowed to stand about a fortnight, and then filtered. It is of an orange yellow colour, is soluble in alcohol, and reddens litmus paper powerfully. It is an exceedingly powerful cathartic; Croton oil is procurable in most Indian bazars.—*M. E. J. R. Faulkner*.

(2972) CROTON PAVANA. AVA CROTON. Lindley says that there is an indigenous species at Ava, which is decandrous, while *C. Tiglium* has fifteen stamens.—*Mason*.

(2973) CROTON ROXBURGHII, Wall. Croton polyandrum. *Roxb.* iii. p. 682.

Hakoon, HIND,	Konda amadum, TEL.

Perennial, native of Circar hills, seeds exactly like those of the castor oil plant, but much smaller. Esteemed by the natives of India to be a good purgative, one seed bruised with water being given for each evacuation desired.—(*Roxb.*) —The Burmese cultivate this species of croton, which grows into a thick bush, and whose seeds are also a strong purgative.—*Mason*. It is very common on the banks of the Jumna, where it is called Jumalghota.—(*Royle.*) *O'Sh.* page 555.

(2974) CROTON SANGUIFLUUM furnishes a product strongly resembling Dragon's blood (Damulukwain).—*O'Shaughnessy*, *page* 555.

(2975) CROTON SEBIFERUM. Pippalyang, *Hind.* Syn (Stillingia sebifera, Michaux: Sapium sebiferum, Roxb. vol. iii. p. 693), seeds covered with a waxy substance, used in China for making candles, now common in gardens round Calcutta.—*O'Shaughnessy*, *p.* 555. In the Dekhan this tree is only to be met with in a few gardens. It is ornamental and bears flowers and fruit for a great part of the year together. The fruit is of a pear shape, yellow and red, which when ripe opens and displays two or three black seeds enveloped partially with a fatty-looking substance. It is this from which the Chinese extract the tallow and make into candles.—*Riddell*.

(2976) CROTON SEED.

Batoo, Dund, ARAB.	Bori, MAL.
Jayapala. CAN.	Dund, PERS.
Nepalam, CYNG,	Nepala, SANS.
Croton, FR.	Nervallum Cottay, TAM.
Jumalgotta, GUZ, HIND.	Naypalum Vittiloo, TEL.
Cheraken, JAV.	

These seeds are about the size of a small marble, of a convex shape on one side, and bluntly angular on the other, enveloped in a thin shell. The Croton tiglium is a native of China, Cochin-China, and India. Many species of Croton have been discovered, all of which are considered as medicinal. Croton seeds are always procurable in the India markets.—*Faulkner*.

(2977) CROTON TIGLIUM. Croton oil tree. *Roxb.* iii. p. 583.

Jamalghota, HIND.	Dund, PERS. ARAB.
Jayapala, SANS.	

The seeds, called *Jamalgota*, were given to Dr. Royle when in India as the *dund* of the Arabs. They were, no doubt, employed at those times, as well as subsequently in Europe, under various names, as *Grana Tilli*, also *Tiglia*, &c., and its wood *Lignum Moluccense*. Having passed out of practice, they were re-introduced by the notices of Dr. White and of Mr. Marshall, published in Ainslie's Materia Medica of India, and by a publication of Mr. Conwell. *Croton tiglium* forms a small tree, of 15 to 20 feet in height, with the young branches smooth and roundish. Leaves oval-oblong, acuminate, 3—5-nerved, with shallow glandular serratures, thin, membranous, with 2 glands at their base, the younger leaves covered with minute stellate scattered hairs. Petioles short, somewhat angular, with a few stellate hairs when young. Stipules 2, subulate, minute. Racemes terminal, erect, simple male at apex, female single, below. Flowers downy. *Male*, Calyx 5-cleft. Petals 5, lanceolate, and woolly. Stamens 15 (15 to 20, woolly at base, *Roxb.*), distinct. *Female*, Calyx 5-cleft, permanent. Styles long, bifid. Capsules oblong, obtusely triangular, the size of a hazel nut, closely covered with

minute stellate hairs; the cells completely filled with the solitary seeds. Skin of the seeds pale dull-brown, overlying a harder, dark, and smooth integument.—*Hamilton* and *Roxburgh*, *C. Jamalgota*, Ham. Linn. Trans. xiv. 258.—Indigenous everywhere in Bengal; found also in the Indian Peninsula and in Ceylon; *Lindley*, Fl. Med. p. 181.

Croton parana (Ham. *l. c.* p. 258), having ten stamens, and the seeds much smaller than their cells, is another species, which yields what Dr. Hamilton considers the original Tiglium seeds. It is a native of Burma, Assam, and Silhet, perhaps also of Amboyna.

Croton Roxburghii. Wall. (C. polyandrum, *Roxb.*) is a native of the Circar mountains; bears seeds to which the name *Jamalgota* is also applied.

Croton tiglium, has a disagreeable smell, and the taste of the leaves is exceedingly nauseous and permanent. (*Roxb.*) All parts of the plant seem provided with an acrid purgative principle, but the seeds are alone now officinal. These are about the size of a grain of Coffee, oblong, rounded at the extremities, with two faces, the external more convex than the internal, separated from each other by longitudinal ridges, and each divided by a similar longitudinal ridge, forming altogether an irregular quadrangular figure. Sometimes when there are only two seeds in the capsule, the internal surface is flat, with a grove formed by the central axis. The shelly covering of the seeds being sometimes partially removed, they have a mottled appearance; but if entirely so, they are blackish. The kernel is oily, of a yellowish-white colour when fresh, but becoming brownish by age. It has a large embryo, with leafy cotyledons. In India the seeds with their covering are subjected to torrefaction, and the embryo usually separated before they are prescribed medicinally. In Europe their effects are obtained by prescribing the Oil, commonly called *croton Oil.* This is obtained by bruising the kernels, and subjecting them to pressure, when about 50 per cent. of Oil may be obtained. But some Oil is also imported from Ceylon. According to Dr. Nimmo, the seed consists of 64 parts of kernel and 26 of covering, and the kernels yield 60 per cent. of Oil. Croton seeds are powerfully Cathartic, and in very common use in India as Purgative Pills, commonly called *Jamalgota Pills.* The natives usually separate the embryo, and combine the albumen of the seed (which, however, is sufficiently active) with Catechu or Pepper. About a grain, or half a seed, is sufficient for a dose, though they do take larger doses. Croton Oil, is expressed from the seeds, and usually imported from India, chiefly from Madras and Bombay, but also from Ceylon. Croton Oil, when quite pure and fresh, is nearly colourless, but as usually met with, it is rather viscid, yellowish, and even of an orange colour, from over-roasting of the seed. It has a faint but peculiar smell, and a permanent acrid taste, which is most felt in the throat. It is a Drastic Purgative in obstinate Costiveness and torpid state of the Intestinal canal, or when a Hydragogue, or the speedy action of a Cathartic, is required.—*Royle, p.* 553.

(2978) CROTON VARIEGATUM,—An ornamental shrub commonly called the laurel, the leaves are variegated; there is also a willow leaf variety equally ornamental and handsome; the plants thrive best in large pots or tubs, and are easily propagated by cuttings. The willow leaf variety thrives best in a situation shaded from the noon day sun.—*Jaffrey.*

(2979) CRUCIANELLA STYLOSA. RUBIACEÆ. This is a pretty little pink coloured flower, native of mountains in Persia and therefore not likely to grow in the southern parts of India.—*Riddell.*

(2980) CRUCIBLES, Musa. Tel.

In India these are made by brass smiths &c. for their own use, of pipe clay or other suitable clay, beaten up for a considerable time on the anvil with burnt paddy husk, being formed they are left to dry and are then ready for use, Mr. Rohde has seen a crucible formed for melting silver simply by spreading wet clay on a bit of rag; which was immediately placed on the fire, which again, was urged by the breath through a bamboo tube.—*Rohde M. S S.*

(2981) CRUSTACEA, Crustacés of the French, Krustenthiere of the Germans. The Common Crab, the Lobster, and Crayfish, the Common Shrimp and the Water-Fleas, may be taken as types of different sections of this family.—*Eng. Cyc. p.* 217.

(2982) CRYPTOGAMIC PLANTS. Not only from the Lichen tribe, but also from the Algæ, fungi, mosses and ferns, man derives nutriment and valuable products. Some of the Cryptogamic plants form considerable articles of commerce, particularly as food plants, affording gelatinous and amylaceous matter, and being useful in medicine and the arts.—*Simmonds.*

(2983) CRYPTOMERIA JAPONICA. The Japan cedar is a tree which has been introduced into England, from China, and which, even in a young state, had been greatly admired there.—*Fortune's Tea District, page* 212. At another place the same author observes "most conspicuous, was the beautiful *Cryptomeria*, or Japan cedar, to which I have more than once alluded in these pages. It is evidently in high favour with the priests of Buddha, and well deserves to be so.—*Fortune's Tea Districts, page* 304. And at another place he says, "among these, I met

for the first time with the beautiful Cryptomeria Japonica, a species of pine not unlike the Araucarias of Norfolk Islands and Brazil. When growing luxuriantly, it is highly ornamental, rising from the ground as straight as a larch, and sending out numerous side branches almost horizontally from the main stem, which again droop towards the ground in a graceful and "weeping" manner. The wood of the tree has a kind of twisted grain, and possesses great strength and durability. It is highly valued by the Chinese and from its beauty and straightness is often used by the Mandarins and priests for those long poles which are generally seen in front of their houses and temples. It is also well known and highly prized by the natives of Japan.—*Fortune's Wanderings, page* 128.

(2984) CRYPTOSTEGIA GRANDIFLORA. The Palay is a climbing plant, belonging to the family Asclepiadaceæ. It yields a very fine strong white fibre, which resembles flax, and is susceptible of being spun into the finest yarn. At the Madras Exhibition of 1855, Mr. Underwood exhibited this fibre in the clean state, and spun into yarn of different qualities, and it appears to be deserving of attention, as the plant is common, and yields a considerable per centage of Fibre. At another place it is mentioned that Mr. Underwood also exhibited a variety of yarns of different qualities made from the Palay or Cryptostegia grandiflora, suited to the weaving of different qualities of cloths. The Palay seems to be a good substitute for flax as it is soft, pliant and susceptible of being split into the finest threads. The stalk contains a large per centage of fibre, besides yielding a milky juice which solidifies into a gum elastic of the nature of India rubber. This appears to be one of the most promising fibres brought to the notice of the Jury. Samples of the concrete juice of this handsome climber were sent to the Madras Exhibition from Nellore, from Masulipatam, from Cuddapah, and from Madras. This strong climbing plant is found in abundance along the Eastern Coast, and in some places is a standard. The milky juice has long been known to contain caoutchouc, but it has not as yet been collected for the purposes of commerce, and it is doubtful, if a sufficient quantity could be obtained to render it an article of trade. The small samples forwarded appeared to be of excellent quality and answered well for rubbing out pencil marks from paper. Mr Underwood made a fair attempt at producing water proof cloth by simply running the juice over the cloth which received Honorable Mention.—*M. E. J. R.*

(2985) CTENOID FISHES, a great division of Fishes, thus named by Agasaiz, from the pectinated appearance of the rectral edges of the scales.—*Engl. Cyc. page* 241.

(2986) CUBEBS, CUBEB PEPPER. See article Cubebs; in Catalogue 1st, Section 1st.

Kebabeh, ARAB.	Komoonkoos, MAL.
Walgummeris, CYNG.	Cabab-cheenee, PERS.
Cubebes, FR.	Cobebas, PORT.
Kubeben. GER.	Kubebn RUS.
Cabab-cheenee, Doomkee mirchee, GUZ. HIND.	Sughunda-marichu, SANS.
Cubebi, IT.	Cubebas, SP.
Kumakus, JAV.	Valmellagho, TAM.
Piper-cubeba, LAT.	Salavamirriaiob, TEL.
	Cubab Chine.

Cubeb pepper, as it appears in commerce, is stated to be the fruit of two different species of pepper, the Piper cubeba, and Piper caricum, both natives of Java, to which island their cultivation appears to be confined. In the Javanese language its name is kumukus, and this is its only specific one, for the Malay name lada barekor, meaning "tailed pepper," is a factitious one derived from the appearance of the dried fruit, which has always the foot-stalk adhering to it.—*Crawfurd's Dict. page* 117. The fruit of Piper cubeba, when ground, should afford 10 per 100 of essential oil, on distillation with water.—*Irvine.*

(2987) CUCULIDÆ, the *Cuckoo-Tribe*, or Cuckoos, a family of Scansorial Birds, placed by Cuvier and Lesson next to the Wrynecks, Yunx. —*Eng. Cyc. p.* 242.

(2988) CUCUMBER, GREEN AND WHITE. —This vegetable is grown from seed at all seasons. The plants should never be too close. It thrives in all parts of India, and grows with much or little water; and if allowed to climb over sticks, or trellis work, is out of the way of jackals and porcupines, who are fond of the fruit. The natives grow them in their fields, in the cold season, amongst grain of various sorts, and in the sandy beds of rivers during the hot weather.—*Jaffrey.*

(2989) CUCUMBER SEED OIL. CUCURBITA PEPO.

Valerikai yennai, TAM. | Thosa noona, TEL.

A clear edible oil. The seeds of the plants of the cucumber family frequently supply a bland oil, which is used in the East as a lamp oil and for cooking. Among the vegetable oils imported into Ningpo, and other Chinese ports, from Shantong, Leatong, and Teisin, are "*oil of teuss*," obtained from green and dried peas, black oil of the fruit of the tree kin (?) and oil from the pea of Suchau.—*Fortune.*

(2990) CUCUMIS, a genus of Plants belonging to the natural order *Cucurbitaceæ*, comprehending the Melon, the Cucumber, and some sorts of Gourd. It is distinguished from the neighbouring genera by its three thick split stigmas, and by the seeds having a thin margin.—*Engl. Cyc. page* 252.

(2991) CUCUMIS ACUTANGULUS. Acute Angled cucumber.

Peekunkai, TAM.	Djingi, MALAY.
Toorai, DUK.	Dumargava, SANS.
Beerakaia, TEL.	

This angular shaped species of Cucumber is a favourite pot vegetable of the Natives of India, who consider it very wholesome, and dress it in various ways. The plant appears to be the Picinna of the Hortus Malabaricus.—*Ainslie, p.* 243.

(2992) CUCUMIS COLOCYNTHIS. Colocynth, or bitter apple. Colocynth Gourd. (Κολοχυνθις, Dioscorid.)

Indrain, HIND.	Hinzil, PERS. & ARAB.
Vishala, SANS.	

The plant grows on sandy lands of Coromandel, Kaira in Guzerat, Tirhoot, and the Doab, especially near Dehlee. Pereira describes two varieties of seeds, one white, the other black, or brownish: the latter very bitter, but he states that both have this flavour. Duncan, however, on the authority of Captain Lyon, describes the seeds as constituting an important article of food in northern Africa. The seeds of the Bengal colocynth are certainly bitter, and when given in half drachm doses produce decided cathartic effects. According to Vauquelin's analysis, Colocynth contains a resinous matter insoluble in ether, a peculiar bitter principle (colocynthine), fat, oil, extractive, gum, and salts. The pulp and seeds of the colocynth produce exceedingly powerful cathartic and emetic effects; from large doses amounting to acrid poisoning. The alcoholic or watery extract however when given in proper doses, and combined with milder purgatives, constitutes one of the most valuable of our medicinal resources. The compound extract of our Pharmacopœia contains, besides the alcoholic extract of colocynth—aloes, scammony, cardamums and soap. It is an excellent purgative, especially when given with blue pill or calomel. The dose is 5 to 10 grains. Numerous formulæ for its administration will be found in our Pharmacopœia. Dr. Burn, of Kaira in Guzerat, sent specimens of the colocynth of that district, and of an extract of his preparation. These articles were identical in action with the colocynth of the Doab, and both were quite equal to the best imported from Europe. These facts are of much importance, especially to the native practitioner, inasmuch as the compound extract of colocynth costs at least 1*l.* 1*s.* the pound avoirdupois. The extract made in Calcutta costs but four rupees per lb. The colocynth of India is moreover likely to become a profitable export, either in the state of fruit or extract. In 1839, 10,417 lbs. were imported into England from Mogadore or the Levant.—*O'Shaughnessy, page* 344. The colocynth Gourd plant, which furnishes the drug Colocynth, is also found wild in the Grecian Archipelago, Egypt, and the north-eastern parts of Africa generally. Burckhardt saw it covering large tracts in Nubia, and Roxburgh speaks of it as common on the coast of Coromandel. It is doubtful however whether the plant of the latter botanist is not rather *C. Pseudo-Colocynthis.* This species grows like a cucumber, but has cordate-ovate many-cut and lobed leaves, white beneath with hairs. Its fruit is small, round, deep yellow, smooth, hard externally, with an intensely bitter pulp. The gourds are gathered in autumn, when they are beginning to turn yellow; they are then peeled and dried rapidly in stoves. —*Eng. Cyc. page* 252. Dr. Irvine tells us, that it is a common wild fruit in November, all over Ajmeer and Jaipore. Buffaloes eat the bitter fruit with apparent zest, and uninjured.—*Irvine. Med. Top. page* 209.

(2993) CUCUMIS MELO.

Melon, TEL.	Beteekh, ARAB.
Melam pullum, TAM.	Bakacoy, MAL.
Khirbooza, HIND and DUK.	Sabo frangee, MALAY.
Khirboozeh, PERS.	

The native country of this valuable plant is unknown. Linnæus says Tartary, but his authority is not given, and in all probability is erroneous; De Candolle says Asia; Roxburgh only knew it in a cultivated state in tropical India; and Professor Royle seems unacquainted with any wild station for it in the Himalaya regions. Cashmere is the most likely to be the country whence it sprang; for it seems to be the mother of many of our other cultivated fruits, and has from time immemorial been famous for the excellence and abundance of its melons, which form a staple article of the food of the inhabitants.—*Eng. Cyc. p.* 252. In Ajmeer, two delicious small varieties of Melon grow wild in Marwar, Beekaneer and Jassulmeer: they are very small and high flavored, and are exported as delicacies. They probably are the Cucumis madraspatanus (*Hind.* Bungunuk) and the Cucumis turbinatus (*Hind.* Kackari).—*Irvine. Med. Top. p.* 209.

(2994) CUCMIS MOMORDICA.

Phoont, Tooti, HIND.

Cultivated and wild at Ajmere in the rains.—*Gen. Med. Top. p.* 210.

(2995) CUCUMIS MURICATUS. Klein.

Cacary kai, TAM.	Kurkotakie, SANS.
Mooloo Dosa Kaia, TEL,	

The natives make this species of Cucumber into curries and other dishes.—*Ainslie p.* 236.

(2996) CUCUMIS PSEUDO-COLOCYNTHIS, Royle. Plains of northern India, where it is called "Indrayun," and "Bisloombhee." The fruit is similar in quality to colocynth, and is substituted in northern India for the true article. On application to Dehlee for specimens of the Bislombhee, Dr. O'Shaughnessy was favoured by

Dr. Macintosh, and subsequently by Dr. Ranken, with fruits which corresponded in every respect with the description and characters of the real colocynth. Dr. Burn's specimens were also identical with the true article, though called "Indrayun" and "Bislombhee." There can be no doubt then, and taking into account moreover the extreme cheapness of the dried fruit in the Bazars, that the real colocynth exists in the Doab and Guzerat, and is called by the names applied by Dr. Royle, to his *Pseudo-colocynthis*. But it is also equally evident that Dr. Royle's article is a peculiar species, perhaps more abundant than the genuine kind.—*O'Shaughnessy, p.* 345.

(2997) CUCUMIS SATIVUS. Linn. CUCUMBER.

Vullerikai, TAM.	Caukreecoy, MAL.
Kunkurie, DUK.	Timmoon, MALAY.
Dosakaia TEL.	Mootrulla, SANS.

The Cucumber, has rough stems bearing tendrils ;—*Eng. Cyc. page* 252. Cucumis sativus, and its varieties are said to be an unwholesome vegetable for delicate constitutions : raised from seed which should be two or three years old, sown where intended to fruit, requires a free rich soil. English varieties should be trained on trellises ; when the shoots are 2 feet in length the points should be pinched off to cause them to branch, used in salads and pickles ; sown after the rains are over at Madras, in January, Feb. and March.—*Jaffrey.* Cucumbers, Cucumis sativus and utilissimus, are consumed in immense quantities, by the Karens and Burmans, who seem to prefer them when large and yellow, rather than pluck them when green and tender.—*Mason.*

(2998) CUCUMIS TUBEROSUS, Heyne.

Adulaykai, also Nellay peekoo. TAM, | Casarakaia, TEL.

This is a pot vegetable not much in request. it is eaten by the common people, who make it into curry.—*Ainslie, p.* 336.

(2999) CUCUMIS USITATA.

Vellaree-kai, TAM.

Cucumber is commonly cultivated by the natives and eaten when ripe as a desert. Cucumis sativus and utillissimus are also cultivated to a great extent and generally eaten green, without any preparation whatever : the country cucumber is very bitter at both ends, these should be cut off before preparing for salad : probably the above are only varieties of each other.—*Jaffrey.*

(3000) CUCUMIS UTILISSIMUS.

Kaukoor, kurktee, BENG. | Kakui, kakri. HIND.

The powder of the toasted seeds is described as a powerful diuretic, and serviceable in promoting the passage of sand or gravel.—*O'Shaughnessy, page* 343. *C. utilissimus*, is an annual and native of the higher cultivated lands of India, but generally found in a cultivated state.—*Eng. Cyc. page* 252.

(3001) CUCURBITACEÆ or GOURDS. This natural order of the Vegetable Kingdom, are herbaceous, annual, very rarely perennial plants. The fruit varies much in size, form, and external characters, but is generally fleshy within, and its pulp is often so saturated with water that it cannot be dried. The roots of most of the order contain starch, often associated with an acrid poisonous matter, which can be separated by washing the powdered root with water, in which the acrid matter dissolves, while the starch is left. The seeds of most of the order are of a mild sweet taste, give good emulsions with water, and yield a fixed oil by expression. Few of the plants of this order are indigenous in Europe. In tropical countries this order gives the inhabitants a large portion of their food, which it often affords of the finest quality in the most arid deserts or on barren swamps and islands. In Persia, China and Cashmere they are cultivated on the lakes, on the floating collections of weeds common in these localities ; in India, they are everywhere abundant, either in the wild or cultivated state. In the East we find the genera Lagenaria, cucumis ; Luffa ; Bryonia ; Momordica ; Trichosanthes, and muricia, and the following is a list of the chief *Dietetical species*, (Royle, p. 219.)

Cucurbita Pepo. (pumpkin,)	Meetha kuddoo. The seeds of these yield oil by expression, and are considered "cooling medicine."
——— Citrullus, ...	Turbooz. A variety, Tentsee.
Benincasa cerifera, ...	Peetha.
Cucumis Melo (melon.) ...	Kurbooza, Seeds oily, and readily become rancid.
C. madaraspatensis,... ...	Roxb. Fl Ind. iii. p. 723.
C. patescens,...	Wild, common near Saharunpore, becomes aromatic on ripening.
C. momordica,...	Phoot.
C. sativus : cucumber,... ...	Kheera. Fruits contain sugar, seed yields a mild oil.
C. utilissimus, ...	Kukree.
Luffa pentandra, ...	Ghia.
——acutangula, ...	Kaleetori.
Momordica charantia,... ...	Kurella, fruit slightly bitter and tonic.
Trichosanthes anguina, ...	Chuchinga.
——— dioica, ...	Palwal.
——— cucumerina,	Junglee-chuchinga.

—*O'Shaughnessy, p.* 351.

According to Dr. Hunter, the *Cucurbitaceæ*, or the Cucumber and Melon tribe, which are so extensively cultivated in all tropical countries as food for the natives, abound in fibres of great length. Indeed, many of the plants which are cultivated in fields or gardens would yield fibre in considerable quantities, which would be useful to the paper-maker, instead of being wasted or burnt. Of these we may instance, among the large family called *Compositæ*, the plant called Jerusalem artichoke, the stems of which abound in fibres. So probably does also the extensively cultivated *Carthamus* or Safflower.—*Royle's Fib. Plants, page* 301.

(3002) CUCURBITA AURANTIA, the Orange-Gourd, is rather more tender than the other species.—*Engl. Cyc. page* 253.

(3003) CUCURBITA CITRULLUS. Lin. WATER MELON.

Pitchee pullum, TAM.	Hindooanch, PERS.
Turbooze, HIND. & DUK.	Darbojee, TEL.
Beleekhzickee, ARAB.	Mandekee, MALAY.

Its deeply-lobed and gashed leaves, and its round fruit, with a spotted rind and a cold watery pink or white flesh in which lie a number of black seeds, sufficiently mark this species, which is most extensively cultivated all over India and the tropics of Africa and America, and generally in hot countries, but which is of no value in the north of Europe, where high flavour is required more than cooling properties. This plant serves both for food, drink, and physic to the Egyptians. It is eaten in abundance during the season, which is from May to July. It is the only medicine the common people use in ardent fevers; it is gathered when ripe or almost decaying; the juice is expressed, and mixed with sugar and rose-water. It is generally considered to be the Melon of the Jews mentioned in many parts of the Bible.—*Engl. Cyc. page* 253. In India, the water melon is cultivated in river beds, and in alluvial deposits of lakes, tanks, &c. where abundance of water can be had; used as a dessert.—*Jaffrey.*

(3004) CUCURBITA HISPIDA, Thunb. RED PUMPKIN.

Poosnikai, TAM.	Goomadikaia, TEL.
Mitta kuddoo, DUK.	

This grows in great abundance in the Tenasserim province and is a pot vegetable much and justly esteemed both by Europeans and Natives. There is a variety of the Poosnikai, called by the Tamools, Kaliana Poosnikai, which is white and which, from old custom and religious rite, must make a dish at every Malabar marriage dinner: it is supposed to ensure prosperity to the wedded pair.—*Ainslie, p.* 244.

(3005) CUCURBITA LAGENARIA. Lin. WHITE PUMPKIN.

Chooray kai, TAM.	Anapakaia, TEL.
Kurreakuddoo, DUK.	Labo ambon, MALAY.
Tomra kudoo, HIND.	Belaschora, HORT. MAL.

There are several varieties of this which are eaten by the natives dressed in different ways.—*Ainslie, p.* 238. Long, white gourds are hollowed out and made into rafts for passing rivers on. The large round kind are used for making a kind of stringed intrument called in Tamools Kinnayrie; and are hence termed Kinnayrie Chooraykai. A longer and narrow sort are employed in making the wind instruments called in Tamool Maghadie with which the snake-men (Pamoo Poodarer, *Tam.*) entice snakes from their holes.—*Ainslie's Materia Medica, p.* 172. In China the dried bottle-gourd are tied to the backs of children on board the boats to assist them in floating if they should unluckily fall overboard.

(3006) CUCURBITA MAXIMA.

Poosheeny-kai and keeray, TAM.

Cucurbita maxima, the common large Gourd, red Gourd, or Squash Gourd, has cordate leaves, very rugged hispid petioles.—*Engl. Cyc. page* 253. Fruit roundish, generally cultivated, the leaves make excellent greens, and the fruit is used for various culinary purposes; require good soil and abundance of water. In Tenasserim this species of large pumpkin or gourd, is a common vegetable seen on the tables of Europeans. "When boiled," says Wight, "it resembles in taste a fine, tender carrot."

(3007) CUCURBITA MELOPEPO.

Khukoor, HIND.

Squash Gourd, has cordate obtuse leaves, somewhat 5-lobed.—*Engl. Cyc. page* 253. This is cultivated over the houses in the rains. In Bengal it is called Suphura-koomra.—*Genl. Med. Top. page* 209.

(3008) CUCURBITA OVIFERA, Egg-Bearing Gourd, or Vegetable Marrow, Sheeray-poosheeny-kai, *Tam.* Probably introduced, said to be indigenous at Astrachan; an excellent vegetable; of easy culture in good rich soil. One of the most wholesome of the cucumber tribe,—*Jaffery.*

(3009) CUCURBITA PEPO. PUMPKIN.

Koomroo, Kudima, HIND.

Large and small varieties much cultivated: the Kudima is a sweet kind, Petha is the long white variety.—*Genl. Med. Top. p.* 209. *C. Pepo*, the Pumpkin, has cordate obtuse leaves. —*Engl. Cyc. page* 258.

(3010) CUDBEAR, is a powder used in dyeing violet, purple, or crimson; it is procured from the *Lichen tartaricus*, a plant found in Iceland. Its colors are not durable when it is employed alone, and it is therefore used as a body to other expensive dyes, as indigo, cochineal, &c. making them more lively. It is used but little by the Chinese, and the demand in that market is not great.—*Compendious Description.*

(3011) CULLENEA EXCELSA. BOMBACEÆ, 1761.

Malay konjie marum, TAM.

A very large and tall tree, trunk straight, from 60 to 80 feet high. Wood white, rather open grained, apparently not very good, but the outside sap-wood only was examined. Under the microscope its longitudinal section is very peculiar; altogether such as I have not elsewhere observed.—*Wight.*

(3012) CUMBI: GARDENIA LUCIDA.

Dikamillie, DUK. GUZ.	Cumbi-pisin, HIND.

A strong disagreeable smelling gum-resin;

procurable in most Indian bazars. It is much used by native doctors as an external application, when dissolved in spirits, for cleaning foul ulcers. It is now used by some European practitioners in cases of worms in children.—*Faulkner.*

(3013) CUMBLY. Gongali, Tel.

Cumblies are woven in almost every district of India, of the wool of the country which is spun by hand. The yarn is sized with the juice of the common squill; the woof is beaten with a hand batten (in the way that sailors adopt in forming mats for defending the rigging) no reed being used: A finer description of cumbly of which the Sepoy cloaks were made is manufactured at Bellary or in its neighbourhood.—*Rohde M.S.S.* Cumblies are manufactured chiefly in Mysore and the Bellary district. The former are of superior qualities, in black and white colours and are sold at from Rupees 25 to 100 each; ordinary sizes 4 to 20 Rs each. Bellary cumblies are well made but are not of so high value as those of the Mysore District, they are 6 cubits long by 3.

(3014) CUMINUM CYMINUM, (Cumin) Κυμινον ημερον, Doiscor. Kumoon, Zeera suffed —Upper Egypt, Ethiopia. Cyminum or Cuminum, a genus of plants belonging to the natural order *Umbelliferæ. C. Cyminum*, the Cumin, is a plant of annual duration, found wild in Egypt and Syria, and cultivated from time immemorial for the sake of its agreeable, aromatic fruit, which, like that of Caraway, Dill, Anise, &c. possess well-marked stimulating and carminative properties.—*Eng. Cyc. page* 274. Its fruits resemble others of the order in stimulant and stomachic properties, and are used in a stimulating plaster. They yield a large quantity of essential oil, of a yellow colour, lighter than water.—*O'Shaughnessy, p.* 367. Cumin is said to be employed in flavouring Dutch cheese. The fruits are carminative, but the smell is disagreeable. They are chiefly used in veterinary surgery. Combined with resin they make a warm stimulating plaster.—*Eng. Cyc. p.* 275.

(3015) CUMIN SEED.

Kemun, Arab.	Cumino, It.
Jeera-Suffeid, Beng.	Jintan, Mal.
Jeeraga, Can.	Zeera suffeid, Pers.
Dooroo, Cyng.	Cominho Port.
Kummen, Dan.	Jiraka, Ajaji, Sans.
Komyn, Dut.	Comino, Sp.
Cumin, Fr.	Siragum, Tam.
Kumin, Ger.	Gilakara, Tel.
Jeera-Suffeid, Guz. Hind.	

Are of an ash-gray colour, oval, linear, flat on one side, convex and striated on the other; having a strong peculiar smell, and a bitter, acrid, aromatic taste. They are used as an ingredient in curries, and also in medicines.—*Faulkner.* Cuminum Cyminum, *Linn.* Common Cumin. Cumin (*kumoon* of the Arabs) is probably a native of Asia, and was made known to the Greeks from Egypt. It is extensively cultivated in the East, but has long been introduced into the south of Europe. England is chiefly supplied from Sicily and Malta. Cumin seeds, or rather fruits, are of a light-brown colour. The odour is aromatic, dependent on the volatile oil which is stored up in the seed-coat. Taste warm, bitterish, and aromatic, but not so agreeable as anise. The albumen is insipid. 16 cwts. of the fruit yield about 44 lbs. of the oil, which has a Sp. Gr. 0·945, pale yellow colour and is limpid, of a disagreeable smell and acrid taste. It is a stimulant Carminative used as a Condiment in India. Seldom used in medicine. Dose gr. xv.—oz. ½. Dr. Formerly much employed as an external application in Emplastrum and Cataplasma Cumini, and by Jews in the process of circumcision.—*Royle.* This pleasant tasted aromatic seed is particularly prized by the Mahometans, who season their cakes with it. Dr. Ainslie thought that much of what is used in this province was brought from China, it also comes occasionally to India from the Gulph of Persia.—*Ainslie, Mat. Med. p.* 266.

(3016) CUNG-QUA. The Cungqua, is a resting place for travellers, or rather for officers of Government in Lew Chew. The Cung-qua corresponds very nearly to the Turkish Khan, except that, being used only by persons of some consideration it is far more neat and elegant in every respect. The house resembled a private dwelling of the better class.—*American Expedition to Japan, page* 189.

(3017) CUNNINGHAMIA LANCEOLATA. In this region I met with no plants which I had not seen before in other parts of the country. I observed this, the lance leaved pine, in great abundance; indeed, this species and the more common Pinus sinensis are almost the only trees of any size which grow in this mountainous district. The natives amongst these hills were much surprised at the sight of a foreigner, and came crowding from all quarters to see me; they were however much more civil and respectful than their countrymen in the low-lands and at Foo-Chow.—*Fortune's Wanderings, p.* 38.

(3018) CUPHEA, Lythraceæ. This genus of plants is rather pretty; the flowers being purple, scarlet and red, are grown from seed and by cuttings in tolerable light soil.—*Riddell.*

(3019) CUPRESSUS, a genus of Plants belonging to the natural order Coniferæ.—*Engl. Cyc. p.* 257.

(3020) CUPRESSUS FUNEBRIS. The funereal cypress. But the most beautiful tree, says Fortune, found in this district of China is a species of weeping cypress, which I had never met with in any other part of China, and which was quite new to me. It was during one of my daily rambles that I saw the first specimen. About half a mile distant from where I was, I observed a noble-looking fir-tree, about sixty feet in height,

having a stem as straight as the Norfolk Island pine, and weeping branches like the willow of St. Helena. Its branches grew at first at right angles to the main stem, then described a graceful curve upwards, and bent again at their points. From these main branches others long and slender hung down perpendicularly, and gave the whole tree a weeping and graceful form. It reminded me of some of those large and gorgeous chandeliers, sometimes seen in theatres and public halls in Europe. Its stem was perfectly straight, like *Cryptomeria*, and its leaves were formed like those of the well-known arbor-vitæ, only much more slender and graceful.—*Fortune's Tea District, p.* 61 and 62.

(3021) CUPRESSUS GLAUCA.

Surus, Duk.

This is a tall, elegant, and graceful tree, well adapted for border walks in a garden, being always green, and a favorite with the Natives. It grows easily, and is generally planted alternately with Areca. Slips, if taken off before the commencement of the rains, and planted in beds shaded from the sun, take root; each slip should be six inches apart, and if common care is used, one-fourth of the plants will strike and grow. After that they may be put out in nursery beds, at the distance of one foot from each other, until required for transplanting, to where they are to remain.—*Riddell.*

(3022) CUPRESSUS HORIZONTALIS, the Spreading Cypress, is a handsome species.—*Engl. Cyc. p.* 258.

(3023) CUPRESSUS LUSITANICA, the Cedar of Goa, differs from the two preceding in its much freer mode of growth, and in its leaves having a singularly glaucous colour.—*Engl. Cyc. page* 258.

(3024) CUPRESSUS PENDULA, Drooping cypress, *Goa cedar.* South of Europe, fruits formerly deemed astringent, and much used in medicine, now obsolete. The oriental physicians used to send their patients labouring under lung diseases to breathe the air of Candia, where the cypress was abundant, in the persuasion that the emanations were particularly wholesome.—*O'Shaughnessy, page* 621.

(3025) CUPRESSUS SEMPERVIRENS, Evergreen cypress, *Suroo* and *Shujr-ul-hueyat,* or the tree of life, *Hind.* Sarass, Its berries and leaves are popularly deemed a panacea for all diseases.—*O'Sh. page* 621. Cupressus Sempervirens is found in gardens at Ajmeer and Kotah. —*Gen. Med. Top. p.* 208. The Cypress is a native of the warmer parts of Europe, but has long since been transferred to gardens for the sake of its deep evergreen branches and leaves. —*Eng. Cyc. page* 258.

(3026) CUPRESSUS TORULOSA, which stood prominently out from amongst the other trees, and a distinct variety of the same species, was said to be from Cashmere.—*Fortunes' Tea Districts, page* 364.

(3027) CURCULIGO ORCHIOIDES: *Roxb.* NELEPANNAY ROOT.

Nelepanay kelung, Tam. | Nelatatie gudda, Tel.
Siah Mooslie, Duk. | Moossalie, Sans.

This tuberous and wrinkled root is in a slight degree bitter and mucilaginous to the taste, it is prescribed in electuary.—*Ains. Mat. Med. p.* 94.

(3028) CURCUMA, a genus of Plants belonging to the natural order *Zingiberaceæ.* It has the tube of the corolla gradually enlarged upwards; the limb 2-lipped, each lip 3-parted; the single filament broad; the anther incumbent, with two spurs at the base; the style capillary; the capsule 3-celled; the seeds numerous, arillate. The species are stemless plants with tuberous roots; the flowers are of a dull yellow colour, surrounded by bracteolæ.—*Engl. Cyc. p.* 261.

(3029) CURCUMA AMADA, "Mango ginger." *Vern.* Amada, *Beng.* Roxb. i. p. 53. A native of Bengal. The name of mango-ginger is given to this root from its peculiar smell while fresh. It is a gentle stimulant, but now only used as an article for seasoning food.—*O'Shaughnessy, page* 649. Mango-Ginger, has few-flowered central spikes; the tubers horizontal, palmate, of a deep orange colour inside; leaves radical bifarious, petioled above their sheaths, lanceolate, cuspidate, smooth on both sides, from 6 to 18 inches long by 3 to 6 inches broad. This plant is a native of Bengal, and is called in Bengalee, Amada.—*Engl. Cyc. page* 261.

(3030) CURCUMA ANGUSTIFOLIA.

Tikor, Hind. | Curcuma angustifolia var. Roxb.
Kooay kalung, Mal.

C. angustifolia, with stalked, narrow, lanceolate leaves, is a native of the forests of India, from the banks of the Sone to Nagpore. Its tubers, which are found at the end of fleshy fibres which meet together, forming a crown, yield an excellent arrow-root, which is that met with in the markets of Benares.—*Eng. Cyc. page* 261. Kooay, or Cooa kalung is the name given to this valuable root, on the Malabar coast, where the natives prepare from it a substance so like their arrow-root, both in appearance and virtues that it is difficult to distinguish the one from the other.—*Ainslie, p.* 249. *Curcuma angustifolia* grows wild in all the hilly parts of the Deccan, and is used by the natives for food. The tubers should be planted in a good rich soil, about one foot apart, just before the rainy season; and taken up as soon as the leaves are dry. Rats, porcupines, and wild hogs, are very destructive to it, both when first planted, and also when ripe. Such tubers as are required for seed should be kept in a dry place in sand. It is very common in India; the roots are used in the Benares district for the manufac-

ture of arrow root.—*O'Shaughnessy, page* 649. East India arrowroot is procured in part from Curcuma angustifolia, known locally as Tikoor in the East, and a similar kind of starch is yielded by C. Zerumbet, C. rubescens, C. leucorrhiza and Alpinia Galanga, the Galangale root of commerce. C. angustifolia grows abundantly on the Malabar coast, and is cultivated about the district of Patna, Sagur and the south-west frontier, Mysore, Vizagapatam and Ganjam, Cochin and Tellicherry. It was discovered but a few years ago growing wild in the forests, extending from the banks of the Sone to Nagpore. The particles of East India arrowroot are very unequal in size, but on the average are larger than those of West India arrowroot.—*Simmonds' Comml. Products, page* 351. Arrowroot (East Indian) from the Curcuma Montana and Angustifolia from Travancore, Cochin and Canara, is a starch which has been prepared in large quantities on the Western Coast for many years, where the farina is extracted from the pendulous tubers of these and other species of Curcuma, and this excellent substitute for the West Indian article, might be produced in large quantities all over the Peninsula. The method of preparing the arrowroot is substantially the same from whichever plant it is extracted. The commercial value of the East Indian farina, is very much below that of the Maranta arrowroot. It is less used as an article of diet, but is largely bought by the starch makers of London. Roots of *kutchoora*, a general name given to the genus Curcuma were sent by Dr. Lovell, Sholapore, to the Madras Exhibition of 1855, as well as arrowroot manufactured from them by the Chinese prisoners at Mahableshwur Hills under the superintendance of Dr. Winchester—the article is sold at 4 annas per pound, giving a good profit—it is of good quality, and is a staple food of the Hill people. The roots appear to be those of Curcuma montana. "Roxburgh." The jury awarded Honorable Mention for this interesting contribution.—*M. E. J. R.*

(3031) CURCUMA LEUCORRHIZA. Roxb. i. p. 30.

Tikor, HIND. and BENG.

Common in Behar; horizontal tubers long and straight, colour very pale yellow—the tubers yield abundance of fine nutritious fecula.—*O'Sh. p.* 649. *C. leucorrhiza* grows in the forests of Behar, where it is called Tikor. It has remarkably long tubers, often a foot in length, of a pale yellow inside, and they produce an excellent arrow-root.—*Eng. Cyc. p.* 261.

(3032) CURCUMA LONGA. Lin. Willd. TURMERIC. Roxb. Fl. Ind. i. p. 33.

Huldi, BENG.	Coonhet, MALAY.
Munjil, TAM.	Passoopoo, TEL.
Huldie, DUK. and HIND.	Manjella cua, HORT. MAL.
Zirsood, ARAB.	Haradul, GUZ.
Zirdchoobeh, PERS.	Haridra, SANS.

Tubers deep orange inside, bitter and aromatic. The colouring matter of the dried root is bright yellow, soluble in alcohol and water, and changed to a deep red by alkalies. White paper dyed by an alcoholic tincture of turmeric is a very sensitive test for alkalies.—*O'Shaughnessy, p.* 649. This is used by the Dyers in dyeing yellow and green. With it in conjunction with lime juice, the Hindoos of the sect of Vishnoo prepare their yellow Tiroochoornum, with which they make the perpendicular mark on their foreheads.—*Ain's. Mat. Med. p.* 203. *C. longa*, the common Turmeric, is cultivated all over India, and is used as a condiment and for dyeing. The root is divided into several fleshy fingers, of an oblong form, and as thick as the thumb. The leaves spring at once from the crown of the root, have a lanceolate figure, sheathe each other at the base, are about a foot long, and produce from their centre a short thick leafy spike, in the axil of whose bracts are seated the inconspicuous, pale, cream-coloured flowers. Dr. Roxburgh gives the following account of the manner in which the plant is cultivated. "The ground must be rich, friable, and so high as not to be drowned in the rainy seasons, such as the Bengalees about Calcutta call Danga. It is often planted on land where sugar-cane grew the preceding year, and is deemed a meliorating crop. The soil must be well ploughed and cleared of weeds, &c. It is then raised in April and May, according as the rains begin to fall, into ridges, nine or ten inches high, and eighteen or twenty broad, with intervening trenches, nine or ten inches broad. The cuttings or sets, namely, small portions of the fresh root, are planted on the tops of the ridges, at about eighteen inches or two feet asunder. One acre requires about nine hundred such sets, and yields in December and January about two thousand pounds weight of the fresh root."—*Eng. Cyc. page* 261.

(3033) CURCUMA RUBESCENS. Roxb. i. p. 28. Tikor, BENG.

A native of Bengal: the root is highly aromatic, but its chief use is for the preparation of *Tikor*—a very fine fecula, like arrow root. This, in Travancore, constitutes an important article of food.—*O'Shaughnessy, page* 649. *C. rubescens* has lateral spikes, the tubers pearl-coloured inside; the leaves bifarious, broad-lanceolate, cuspidate, smooth, strongly marked with parallel veins, of a uniform dark green, with the nerves or ribs red; 12 to 24 inches long, 5 or 6 inches broad; the scapes invested with several dark reddish sheaths. It is a native of Bengal; All the parts of the plant have a pleasant, aromatic smell when the plant is bruised. The pendulous tubers of this and several other species of *Curcuma* yield starch, and are employed by the natives for preparing arrow root. In Travancore it forms the principal diet of the natives.—*Eng. Cyc. page* 261.

(3034) CURCUMA ZEDOARIA. Roxb. i. p. 23.

Bun-huldie, BENG. | Judwar, ARAB.

A native of Bengal and China. This is the *round zedoary*, all kinds of which resemble gingers in their medicinal qualities, but are inferior to it in strength and agreeableness of flavour.—*O'Shaughnessy, page* 649. *C. zedoaria*, Broad-leaved Turmeric, has the spikes lateral; biennial tubers, which are yellow internally; the leaves petioled, broad-lanceolate, entire, underneath covered with soft sericeous down. This is the *Zedoaria rotunda* of the shops. Fee has confounded this plant with *Kæmpferia rotunda*, which has no sensible properties resembling the plant in question. The tubers of this plant are aromatic, and are used by the Hindoos not only as a stimulating condiment and a medicine, but as a perfume. Its sensible properties are very like those of ginger but not so powerful. It is employed in the East in cases of disease, as colic, cramp, torpor, &c. where stimulants are indicated. The Zedoary is used under same circumstances. The roots of both these plants are imported into Europe, but are not used extensively. *C. Zedoaria* is a native of Bengal, China, and various other parts of Asia, and of the Asiatic Islands.—*Eng. Cyc. page* 261.

(3035) CURCUMA ZERUMBET. (Roxb. Fl. Ind. i. p. 20.)

Kuchoora. Shoothee, HIND. & BENG.

A native of the East Indies, found at Chittagong, stemless, roots palmate and tuberous, pale yellow internally, smell pleasant and camphor-like, taste aromatic and bitterish. This is the *long zedoary* of pharmacy.—*O'Shaughnessy, page* 648. *C. zerumbet*, zedoary, has lateral spikes, the tubers palmate pale straw-coloured; the leaves from 4 to 6 together, with a long somewhat winged petiole, with a dark purple cloud running down the centre; the flowers shorter than the bracteolæ; the embroyo truncate, nearly as long as the seed, the upper half lodged in the vitellus, the lower half in the perisperm. This plant is the *zedoaria longa* of the shops, and a native of the East Indies and Java.—*Eng. Cyc. page* 261.

(3036) CURIOSITIES. Under this general term are included a great variety of articles purchased by those who visit China as articles peculiar to the country. It is impossible to particularize them, as they consist chiefly of such things as please the fancy, and are for the most part procured for ornament's sake. Vases, pots, jars, cups, ornamental screens, plates, boxes, &c. made of copper, iron, silver, porcelain, stone, lackered ware or wood, of every shape, size, and variety of workmanship, rings, stands and pedestals, lanterns, scrolls, &c. &c. constitute most of the articles sent abroad as curiosities. The number of shops in Canton where they are sold offers the purchaser an extensive choice. It is impossible to ascertain the amount, but it is probably over $20,000 annually.

(3037) CURRYING OF LEATHER. This is an art but little practiced among Natives of India. The Chucklers by whom every operation is conducted, from the skinning of the beast to the binding of a pair of shoes, shaves the hide or skin down with his knife; beats it and rubs it with his maul and blackens it with iron liquor to which plantain root and conjee water are sometimes added: sometimes a little lamp oil is used.—*Rohde M.S.S.*

(3038) CURRY POWDER. Take of powdered turmeric 22 tea spoonfuls; red dried chillies or Cayenne pepper, 8 Ditto, Coriander seed, Cummin seed, dried cassia leaves (tejpat), each twelve tea-spoonfuls and mix together. The curry powders of India are articles of considerable commercial traffic; 32,550 cwt. of curry stuff was imported into Ceylon, chiefly from India, in 1851.—*Simmonds.*

INGREDIENTS FOR CURRY STUFF.

Native Name.	*English.*	*Botanical.*
Sonf.	Anise seed.	Pimpinella Anisum.
Seetul cheenee gach.	Allspice.	Myrtus Pimenta.
Eelachie	Cardamom.	Elettaria Cardamomum.
Laoong.	Cloves	Eugenia Caryophyllata.
Jawatrie.	Mace.	Myristica Moschata.
Jauphull.	Nutmeg.	Do. Do.
Kulmie darchinie.	Cinnamom.	Laurus Cinnamomum.
Dhunnia or Kotimear.	Coriander.	Coriandrum Sativum.
Zeera	Cummin seed.	Cuminum Cyminum.
Kali mirchie.	Black pepper.	Piper Nigrum.
Rai.	Mustard seed.	Sinapis Chinensis.
Lal mirchie.	Chillies.	Capsicum Frutescens.
Huldie.	Turmeric.	Curcuma longa.
Maytie.	Fenugreek.	Trigonella Fœnum.—Græcum.
Lassun.	Garlic.	Alium Sativum.
Sont	Ginger, dry.	Amomum Zingiber.
Udruck.	Ginger, green.	
Khush-khush.	Poppy seed.	Papaver Somniferum.
Pipel.	Long pepper.	Piper longum.
Hing.	Assafœtida.	Ferula Assafœtida.
Chironjii.	Chironjie nut.	Buchanania Latifolia.
Badam.	Almond.	Amygdalis Communis.
Narel.	Cocoanut.	Cocos Nucifera
Nemuck.	Salt.	

INGREDIENTS FOR MAKING A CURRY WITH MEAT, FOWL, OR FISH.

Mirchie.	Chillies, dry or green, from six to twelve or more.	
Huldie.	Turmeric,	one Tolah.
Dhunnia.	Coriander seed,	one ,,
Zeera.	Cummin seed,	three Mashas.
Elachie.	Cardamom seed,	two ,,
Myatie.	Fenugreek,	three ,,
Sont.	Dry ginger,	three ,,
Kali Mirchie.	Black pepper,	one Tolah.
Nemuck.	Salt,	two ,,
Laoong	Cloves,	twelve,,
Jawatrie.	Mace,	one Masha.
Kulmie Darchinie.	Cinnamom,	one Tolah.
Narel.	Cocoanut,	eight ,,
Chironjie.	Chironjie nuts,	six ,,
Badam.	Almonds,	five ,,
Khush-khush.	Poppy seed,	five ,,
Peaz.	Onions, a table-spoonful, sliced.	
Lussun.	Garlic, from one to three cloves.	
Am.	Mangoe, dried or green, a few slices.	
Emlee.	Tamarinds, fresh or salted, a small quantity.	
Leemboo.	Lime juice, one dessert-spoonful.	
Tyre.	Curds, three table-spoonsful.	
Ghee or Butter, three table spoonsful.		

These are the quantities of the various articles to be used in the preparation of a curry, bearing in mind it is unnecessary to use the whole of the spices together; or the mangoes, tamarinds, or

lime juice, neither the cocoanut with the almonds, and the ginger may be omitted when dry ripe chillies are used, as likewise the cummin seeds with the coriander, both of which are better for being roasted. Cocoanut milk is much used on the coast in forming the gravy to many curries, especially fish and prawns, as well as the oil fresh expressed from the nut when grated. If the curry is to be dry, the onions must be fried brown in ghee or butter, and the ingredients ground to a paste with water, mixed in the same, the meat, and fowl added, stirring the whole until the gravy and butter are absorbed. For a gravy curry, cut the meat or fowl into slices, put the ghee into a stewpan over the fire with the sliced onions and dress them, then add the meat with the ground ingredients, and some water or broth, mix well together and let the whole simmer gently until the meat is properly done. Chundoo is made with meat or fowl that has been previously dressed, it is to be minced up and added to chopped onions fried in ghee, with whole red chillies, and the other curry ingredients well mixed together; the frying is continued until the meat is perfectly brown, and the gravy quite absorbed.

INGREDIENTS FOR CURRY POWDER.

Four Receipts.

	No. 1. lbs.	No. 1. 20 lbs.	No. 2. 12 lbs.	No. 3. 3 lbs.	No. 4.	
Coriander seeds,	"	4	2	1	1	To be well roasted.
Turmeric,	"	1	1	"	2oz	Pounded.
Cummin seeds,	"	1	"	"	"	Dried and ground.
Fenugreek,	"	1	1	"	0	4oz.
Mustard seed,	"	1	"	"	"	
Ginger, dried,	"	2	2	"	1	
Black pepper,	"	2	1	1	1	
Dried Chillies,	"	1	2	1	0	12oz
Poppy seed,	"	2	2	"	"	
Garlic,	"	2	1	"	"	
Cardamoms,	"	"	"	"	0	8oz
Cinnamono,	"	"	"	"	0	8oz

} Dried and cleaned of husks.

Salt in proportion to be added when using the curry stuff. The whole to be cleaned, dried, pounded, and sifted; then properly mixed together and put into bottles, well corked. A tablespoonful is sufficient for a chicken or fowl curry. —*Riddell's Domestic Economy, p.* 404.

(3039) CUSCUS ROOT.

Bala, Duk. | Viratara, Sans.
Cuscus, Useer, Guz. Hind. | Vittie vyr, Tam.
Khus, Pers. | Cooroo vayroo, Tel.

This fragrant smelling root consists of many perennial, long, spongy, brown fibres, which are made into fans, ornamental baskets, mats for palkee tops, &c. Thirty-five species of this grass (*Andropogon*) are distinguished, and which are common in the low rich soils of most parts of India. It is chiefly brought to Bombay from the Malabar Coast.—*Faulkner.*

(3040) CUSCUTA REFLEXA, Convolvulaceæ. Huldi-algusi-luta, Duk.

A parasite with filiform twining succulent stems, leafless, smooth, yellow; flowers white.—*Riddell.*

(3041) CUSTARD APPLE. Anona squamosa.—*Faulkner.*

(3042) CUSTOMS.

Zakhat, Guz. | Gumruk, Mahsool, Pers.

Duties levied on commodities of importance.—*Faulkner.*

(3043) CUSTOM HOUSE.

Gumruck, Guz. Hind. Pers.

A term applied to the establishment by means of which the customs revenue is collected, and also to the building within which the business is conducted.—*Faulkner.*

(3044) CUTTACK forests are composed of teak, sal, Sissoo, ebony, *Pentaptera*, *Buchanania*, and other trees of a dry soil, and that require a dry season alternating with a wet one. These are unknown in the Chittagong forests, which have Jarool, *Lagerstræmia Mesua*, *Dipterocarpi*, nutmegs, oaks of several kinds, and many other trees not known in the Cuttack forests, and all typical of a perennially humid atmosphere.—*Hooker's Him. Jour. Vol.* II. *page* 340.

(3045) CUTTLE FISH, BONE OF. Sepia: Octopoda.

Kaddelnooray, Tam. | Samoodra nooroogoo,
Dirya ka kuff, Duk. | Tel.

This is found on the coasts and used for rubbing down paint &c. by the moochies (*Rohde's M.S.S.*); also for the purpose of cleaning and polishing the surface of silver and other metals.—*Ains. Mat. Med. p.* 152. In *Sepia officinalis* the soft parts are supported by a firm calcareous bone, the well-known cuttle-bone of the shops, and in all the naked Cephalopods (not including *Ocythoe*) now existing it would appear that some rudiment at least of a bony, horny, or cartilaginous support is to be found.—*Engl. Cyc. p.* 820.

(3046) CUTTY, the term applied in Southern India to the Iron-bloom of native manufacture.

(3047) CUTTEAMUNDOO, is the juice of the plant Akoo Chenroodoo or Euphorbia Cuttimundoo, and is used in cementing iron. The "Cutteamundoo" the juice of this plant is used in cementing iron with other substances (the blade and handle of a knife for instance), It is common in the Northern Circars and is called Akoo Chenroodoo—which is described in Campbell's dictionary as "Euphorbia Neriifolia." It is also

called Bramha Chemoodoo. At the Madras Exhibition of 1855, Mr. Elliot exhibited 7 articles (basin, ewer, tumbler, &c.) made of *Cutteamundoo gum*, moulded with the hand, without any preparation. The fresh juice is used as a vesicant, and also as a cement for fastening knife handles, &c. For the introduction of this interesting substance, a medal was awarded to Mr. Elliot at the London Exhibition of 1851, and for the further application of it to useful purposes, the Madras Jury awarded Honorable Mention. Several consignments have been made by Messrs. Healy and Lutrell, of Vizagapatam, and 2 cwts. were sent by request to Professor Solly, Society of Arts, London. The samples exhibited, illustrate the variety of uses to which this gum elastic may be applied. At the same Exhibition, Major General Clarke forwarded from Jaulnah a Hydrocarbon, closely resembling Cutteamundoo gum, obtained from the "*Euphorbia tirucalli*," which is however considerably different from Caoutchouc or Gutta Percha in its physical qualities, for this the Jury awarded Honorable Mention. Also Nursinga Row of Masulipatam forwarded two lumps of a similar substance obtained from "Euphorbia neriifolia" to which the same remarks apply: the Jury awarded Honorable Mention.—*M. E.J. R.*

(3048) CYCADACEÆ, Cycads, the Cycas Tribe, one of the natural orders of Gymnospermous Plants. It is essentially characterised by its trunk growing in a cylindrical unbranched manner, in consequence of the development of one terminal bud only, and by its diœcious flowers, of which the males at least grow in cones composed of pellate scales. In one genus, *Zamia*, the female flowers also are disposed in the same manner. All the species contain starch, and from many it is separated and employed as an article of diet. The species of *Encephalartos* are called Kaffir-Bread. The seeds of *Dion edule* yield starch in Mexico. The same substance, under the name of sago, is obtained from species of *Zamia* in the Bahamas and other West India Islands; in Japan from *Cycas revoluta;* and in the Moluccas and Southern India, the *Cycas circinalis* yields a coarse kind of flour. This species also yields a transpareut gum. The order contains about fifty species. A fine collection of Cycadaceous Plants exists in the Royal Gardens at Kew. A unique collection of these plants has also been recently made by the Rev. J. Yates of Lauderdale House, Highgate.—*Engl. Cyc. paye* 265.

(3049) CYCAS ANGULATA. The fruit forms the principal food of the Australian aborigines during a portion of the year. They cut it into thin slices, which are first dried, afterwards soaked in water, and finally packed up in sheets of tea-tree bark. In this condition it undergoes a species of fermentation; the deleterious properties of the fruit are destroyed, and a mealy substance with a musty flavor remains, which the blacks probably bake into cakes. They appear also to like the fruit of the *Pandanus*, of which large quantities were found by Dr. Leichardt in their camps, soaking in water, contained in vessels formed of stringy bark.—*Simmonds.*

(3050) CYCAS CIRCINALIS. Chiefly occurs in India and the Moluccas; said to yield a sago, also a gum like tragacanth.—*O'Sh. page* 622. It is a very handsome tree, in appearance resembling thePalm tribe,and is common from Tellicherry to the foot of the Ghauts. It is also common, in the Karen forests of Tenasserim.—*Mason.*

(3051) CYCAS PECTINATA, is a Sago palm which grows in Sikkim, on the flats by the streams. Its stem is ten feet high, with a beautiful crown of foliage.—*Hooker, Vol.i.p.*151.

(3052) CYCAS REVOLUTA. A native of Japan; a kind of sago is said to be obtained from the cellular substance. The whole plant yields a copious mucilage, which hardens into a transparent gum.—*O'Shaughnessy, page* 622.

(3053) CYCLAMEN PERSICUM. Primulaceæ. This is a bulbous species of flowering plants thriving in a light vegetable mould and may be cultivated by its seed or tubers.—*Riddell.*

(3054) CYCLANTHERA PEDATA. Liliaceæ. This species of flowering plants is grown, and cultivated as the *Cyclamen.—Riddell.*

(3055) CYAMOPSIS PSORALOIDES. Dolichos Fabæformis.

Coothah Varay-kai, Tam.

An erect annual; cultivated during the cold months in gardens for the little flat pods, which are used in curries, and as a substitute for French beans: grows from 2 to 3 feet high; the pods are seldom very tender.—*Jaffrey.* The natives of Tenasserim cultivate this, which resembles the common European bean, and is esteemed by them a good vegetable.—*Mason.*

(3056) CYATHEA ARBOREA, Tree Fern. A section of this tree fern displays well the structure of an Acrogenous stem, hollow in the centre, marked on the outside by the scars of the fallen leaves, and showing the elongation of the axis by the junction of the petioles. Wood quite worthless as timber.—*Madras Hort. Garden* 87. —*M. E. J. R.*

(3057) CYDONIA, a genus of plants belonging to the natural order *Pomaceæ.—Eng. Cyc. page* 269.

(3058) CYDONIA TOMENTOSA. Woolly Quince. *Hind.* Velaitee Behee. Cultivated in some gardens.—*Gen. Med. Top. p.* 195.

(3059) CYDONIA VULGARIS. (Quince.) Asia Minor, Cabul, Bokhara. *Off* Seeds.

Behedana, Behdana, Hind.

Cydonia, L. Semina. Cydonia vulgaris, *Pers.*

Seeds of common Quince. (*Pyrus Cydonia*, Linn.) *Icosandria Pentagynia*, Linn. Seeds oval, acute, plain at one side, convex at the other, often triangular, truncated at one end, of iron colour, internally white and brilliant. The coriaceous episperm contains a quantity of mucilage which is readily given out to water. The kernel is emulsive. The Beheedana constitutes an important article of commerce, being highly valued as a demulcent tonic, and restorative remedy by the Mahomedans all over the East. In 1838-39, 106⅓ maunds were imported into Calcutta from the Persian Gulf; into Northern India they are brought from Cabul and Cashmere.—*O'Shaughnessy, page* 330. The Quince (χυδονια) was known to the ancients and Arabs; the seeds (*bihee danu*) are employed medicinally in India, being imported from Caubul and Cashmere, where the tree is cultivated. This is a moderately sized, much branched but crooked tree. Leaves ovate, obtuse at the base, quite entire, with their lower surface, as well as the calyxes and pedicels tomentose. Flowers few, of a white or rose-colour in a kind of umbel. The pomes closed, globose or oblong, 5-celled; *cells many seeded*, cartilaginous Seeds enveloped in condensed mucilage.—Nees von E. 305; St. and Ch. ii. 114. The fruit of the Quince is of a yellow colour, downy, and remarkable for a fine odour. The ancients used it as a medicine, but it is now chiefly employed for flavouring other fruits, or as a preserve. It contains some astringent matter, with Malic acid, Sugar, and azotised matter. (*Soubeiran.*) The seeds are oblong, pointed, convex on the outside, and with one or two flat sides, according to the pressure of neighbouring seeds. Their testa, or thick seed-coat, is covered with condensed mucilage, which, according to Bischoff, as quoted by Dr. Percira, is lodged in very fine cells, and becomes easily dissolved out when submitted to the action of boiling water.—*Royle.*

(3060) CYGNINÆ, a sub-family of Web-Footed Birds, belonging to the family *Anatidæ*, order *Anseres* of Linnæus, including the Swans. Only two true Swans are recorded by Linnæus, and those as varieties of *Anas Cygnus* namely, variety A, *C. ferus*, and variety B, *C. mansuetus.* Since his time the researches of zoologists have added considerably to the catalogue.—*Eng. Cyc. page* 169.

(3061) CYGNIA FERUS. (Ray.) Male. Pure white, with occasionally a buff tinge on the top of the head. Bill black, and depressed anteriorly, quadrangular at the base, and yellow, which tint extends forward along each lateral margin of the upper mandible beyond the aperture of the nostrils.—*Eng. Cyc. p.* 270.

(3062) CYMBIDIUM ALOIFOLIUM. *Orchidaceæ.* This is a beautiful plant, when in flower, of a purple and yellow colour, and blossoms in April, native of India. Wight also gives Cymbidium erectum, 1753; tenuifolium, 911, 1689; tesseloides, 916; and triste, 911-1689.

(3063) CYNANCHUM, (from κύων, a dog, and ἄγχω, to strangle), a genus of a Plants belonging to the natural order *Asclepiadaceæ.* It has a 5-parted somewhat rotate corolla; a coronet of appendages consolidated, 5-20-lobed, when 5-lobed with the segments opposite the anthers; the pollen-masses ventricose, pendulous; the stigma usually apiculate, sometimes blunt, very rarely with a beak inclosed below the summit; the follicles smooth. The species are herbs or undershrubs, with opposite leaves and mostly twining stems.—*Eng. Cyc.* Dr. Wight gives Cynanchum alatum, 1280 Callialata, 1270 pauciflorum 354.

(3064) CYNANCHUM ARGEL, has erect, pale, round stems.—*Eng. Cyc. p.* 275. It is a native of Upper Egypt. The leaves and the whole plant act as a powerful drastic purgative. This plant appears to be a native of the same districts as those from which the Alexandrian Senna is obtained, and all the samples of that senna contain these leaves. They do not, however, appear to be added for the purposes of adulteration, but are collected with the leaves of the senna through the ignorance of the persons employed in their collection. The leaves of Tinnevelly senna are not found to contain those of the *C. Argel* mixed with them. Much of the unpleasant griping effect of the Alexandrian senna is attributed by some writers on Materia Medica to the mixture of the leaves of the Argel. Senna leaves are also mixed with those of the *Gouphocarpus fruticosus*, which are in Syria also called Argel, or Arghel.—*Eng. Cyc. page* 275. In small doses the leaves are purgative, and they are much used in Egypt for adulterating senna. (See that article.) The Indian, or Tinnevelly sennas is not liable to this adulteration, to which many practitioners attribute the severe griping which senna often occasions.—*O'Shaughnessy, p.* 450.

(3065) CYNANCHUM EXTENSUM. Iaco.

Vaylie parta, Tam.	Zootoopakoo, Tel.
Utrun, Duk.	Vooghapala, Sans.

The leaves of this herbaceous plant have a disagreeable and somewhat nauseous taste and smell. The juice of them is supposed to possess an emitic, as well as purgative, quality, and is said to be particularly useful in cases of Jaundice: it is generally administered in Cow's milk.—*Ains. Mat. Med. p.* 122.

(3066) CYNANCHUM IPECACHUANA, Mauritius Ipecachuana. A root procured from the Mauritius, and subjected to analysis by Pelletier. Its emetic properties are well established, but it requires to be given in double the dose of the true ipecachuana; great difference of opinion exists as to the plant by which it is supplied.

The article does not occur in commerce, though it may probably be identical with the root of C. Vincetoxicum.—*O'Shaughnessy, page* 451.

(3067) CYNANCHUM OVALIFOLIUM is a smooth twining plant, with oblong oval acuminate leaves: many-flowered cymes; peduncles not longer than the petiole; the coronet 10 cleft about as long as the corolla; the stigma pointed, emarginate. This plant is a native of Penang, where according to Dr. Wallich, it is used for the purpose of procuring from its sap, caoutchouc, which is of an excellent quality.—*Engl. Cyc. p.* 275. *Cynanchum ovalifolium* of Penang, yields abundance of very fine caoutchouc.—*O'Shaughnessy, page* 451.

(3068) CYNANCHUM VIMINALE, Lin.

Kodiculla, Tam.

The young shoots and tender stalks of this creeper are eaten by the Natives. It must not be confounded with the Kallie (or Kodicallie, as it is sometimes called) which is the Tamool name of the milk hedge.—*Ainslie, p.* 254.

(3069) CYNARA CARDUNCULUS: Cardoons. This is similar to the garden artichoke; indeed plants of the latter, which grow to a large size might be used as cardoons; in order to prepare this vegetable the leaves of the artichoke should be cut down, not destroying the heart, at the commencement of the rains, after the young leaves grow to the length of 2 feet, they should be tied together in a bundle, and earthed up like celery, at least one foot of earth should be raised round the plant, they will be fit for use in three weeks or a month, raised from seed. The plants when a good size require to be planted 2 or 3 feet apart in good soil; probably this is the only use to which the garden artichoke could be turned to at Madras.—*Jaffrey.* Cardoon resembles the artichoke, but grows much higher. The tender stalks and leaves when blanched are used for soups and salads, and are cultivated in the same manner as the artichoke.—*Riddell.*

(3070) CYNODON DACTYLON.

Hurrum Pilloo, Tam. | Hurryalee-grass, Eng.

The young and tender leaves of this grass are used in chatnies, a rather curious use, but considered very pleasant, the roots make a cooling drink.—*Jaffrey.* It is one of the most abundant grasses on the Tenasserim Coast, but it is much less conspicuous than many others.—*Mason.* The Cynodon Dactylon or Hurryallee Grass of India, is considered the best for cattle. Root creeping through the loose sand with strong fibres at the nodes. Stem rarely exceeding six inches in height, creeping to a considerable extent, matted, very smooth. Florets all on one side of the spike-stalk awnless, purplish, and ranged in two close alternate rows. All the stems which lie near the ground take root, and by this means, though an annual plant, it increases and spreads very wide. It yields abundance of seed, of which small birds are very fond. It has been very successful to allow the seed to ripen before the hay is cut, as it then propagates itself by seeds, in addition to the runners. This Grass is also found in Great Britain, but in that country its produce and nutritive properties are comparatively insignificant, while here it constitutes $\frac{3}{4}$ of the pasture. Respecting this Grass, Sir W. Jones observes (As. Res. Vol. 4. P. 242) "that it is the sweetest and most nutritious pasture for cattle; and its usefulness, added to its beauty, induced the Hindoos, in their earliest ages, to believe that it was the mansion of a benevolent nymph. Even the Veda celebrates it, as in the following text of A't'harvana: "My Durva, which rose from the water of life, which has a hundred roots and a hundred stems efface a hundred of my sins, and prolong my existence on earth a hundred years."—*Cleghorn, Grasses.*

(3071) CYNOGLOSSUM. Boragineæ. These are pretty little annuals, natives of Europe, the colour of the flowers mostly blue, purple, white and purple, grow in any common soil.—*Riddell.*

(3072) CYNOMORIUM. Dr. Wallich says there is a species of this fungus-like genus, which is parasitical on the roots of trees in the Tenasserim provinces, and valuable as a styptic; but I have not observed it.—*Mason.*

(3073) CYPERACEÆ, Sedges. May be called the Grasses of moist situations, and very closely resemble them in appearance; but they may readily be distinguished by their stems being solid, often triangular, and their leaves with entire, not split sheaths. They are much less useful than the plants of that family. The famed Papyrus belongs to the Cyperaceæ. Though a few do secrete fecula in their tuberous rootstocks, as the Water Chesnut of the Chinese, &c., others secrete a little Volatile Oil, as *Cyperus longus* and *rotundus*. They are mentioned here because the creeping rhizomes of *Carex arenaria*, and of a few allied species, are sometimes used medicinally, under the name of German Sarsaparilla. Sedges nearly resemble grasses in appearance, but grow usually in moist situations, and are distinguished from them by their angular stems. There are few of them useful for any purpose—not even for fodder. One of them, however, is famous as having yielded the Papyrus of the Egyptians, employed by them for making paper, ropes, and even boats; and of which the plant is so frequently represented in their sculpture and painting. An Indian species of Cyperus (*C. tegetum*, Roxb.; called *Papyrus Pangorei* by Nees von Esenbeck), the *Madaorkati* of the Bengalees, which is extremely common about Calcutta and in Bengal, is very extensively employed for making the elegant, shining and useful mats for which the capital of India is famous,

and which are frequently imported into Europe. Dr. Roxburgh states that the culms or stalks of the plant when green are split into three or four pieces, which in drying, contract so much as to bring the margins in contact, in which state they are woven into mats, and thus show a nearly similar surface on both sides. Specimens of the strips of this sedge were sent to the Exhibition of 1851, as well as mats made of them. These strips are tied up in bundles about four inches in diameter and four feet in length; and seem, besides their extensive use for mat-making to be well adapted for platting. The cotton grass (*Eriophorum*) of Europe is a conspicuous ornament of turf-bogs and marshy moors, from having its seeds clothed at the base with a silky or cotton like substance. With this, pillows are sometimes stuffed, and wicks of candles as well as paper, made. There is a species of the genus very common in the Himalayas, both in low valleys and at considerable elevations. This, Dr. Royle named *Eriophorum cannabinum*, in consequence of his finding it everywhere employed in making ropes for all ordinary purposes by the mountaineers. Its name, *bhabhur* and *bhabhuree* has a considerable resemblance to that of the papyrus, considering that the *b* and *p* are letters so frequently interchanged for each other. All who have scrambled up the steeps of the Himalayas are sensible of the great support they have received from the toughness of the tufts of the bhabhur. Specimens of the dried leaves, made up into bundles about three feet in length, were sent to the Exhibition of 1851, from Beerbhoom. Also twine made from it: this, though rough, is strong and well fitted for ordinary purposes. Capt. Huddleston, in a paper on the Hemp and other fibres of Gurhwal, in the Himalayas ('Trans. Agric. Soc. of India,' viii, p. 272), mentions the Bhabhur as holding a conspicuous place, "from its extensive use and most abundant supply throughout the whole of the hills, affording a most economical substitute as an article of cordage, in lieu of others of a more costly and durable nature. All the jhoolas or rope bridges, which are erected over the large rivers, where sanghas or wooden-planked bridges cannot be made, on all the principal thoroughfares of this district, are constructed of this silky species of grass, the cables of which are of considerable thickness. These rope bridges are a very safe means of communication over the large and rapid rivers intersecting different parts of the country, both for travellers and men with loads; and, where the footway and sides are properly laced with brushwood, afford an easy enough roadway for loaded sheep—but neither ponies nor cattle can travel over them. This grass grows abundantly in all the ravines up the sides of the mountains, and is to be had only for the cutting—but it is not of a very durable nature, though pretty strong when fresh made into ropes. It lasts about a twelvemonth only, or a little more, and the people in charge of the rope bridges are constantly employed in repairing and annually renewing the ropes and stays. The 'chinkas,' or temporary bridges of a single cable, upon which traverses a seat in the shape of an ox-yoke, are also sometimes made of this grass."—*Royle, Ind. Fib. Pl. p.* 33.

(3074) CYPERUS ESCULENTUS, Esculent cyperus. The toasted roots have been used as a substitute for coffee, and yield a preparation resembling chocolate. The cultivation of the plant deserves attention for its considerable alimentary value.—*O'Shaughnessy, page* 628.

(3075) CYPERUS GEMINATUS, (twin) Ainslie. Sp. Nov.

Sheelandei arisee, TAM.

Bulbous roots eaten in India, flavour resembles that of sago.—*O'Shaughnessy, p.* 628. This was first brought to the notice of Europeans by the late Dr. James Anderson, who, in an excursion he made to the southern part of the Peninsula some years ago discovered that the Sheelandie arisee, from growing in sandy situations by the sea side and requiring but little water, was the common food of the natives during the famine and when other grains are scarce. It is nutritious, pleasant to the taste and makes a pudding somewhat resembling that made of sago. Dr. Anderson, with that kindness and benevolence which ever distinguished him, disseminated the bulbous roots of this curious plant wherever he thought from their particular qualities they could be beneficial.—*Ainslie, p.* 250.

(3076) CYPERUS JUNCIFOLIUS. Root of the Rush Leaved. *Cyperus.*

Koray kalung, TAM.	Sadcoofie, ARAB.
Nagur mootha, BENG. & DUK.	Toongudda, TEL.
	Moosta, SANS.

Is employed as a diaphoretic and diuretic in India. Its roots are fibrous.—*O'Shaughnessy, page* 627. This fibrous root with its small bulbous extremities is prescribed in decoction in Fever cases: it is supposed to be gently diaphoretic and diuretic, and is reckoned a valuable remedy when there appears to be a tendency to dropsy in the habit.—*Ains. Mat. Med. page* 84.

(3077) CYPERUS PAPYRUS, of the Egyptians, belongs to this genus, and is still called *babier* in Syria. It is about 15 feet high; the exterior tunic of the stems cut in bands, and pressed, formed the paper of ancient Egypt and Europe; the leaves, which are several feet long, served for the same purpose, but were of inferior quality. This paper is but little liable to decay. Pliny, for instance, relates that the book of laws of Numa Pompilius was found in Rome in a high state of perservation, after having been buried nearly six centuries in the earth.—*O'Shaughnessy, page* 628.

(3078) CYPERUS ROTUNDUS. ROUND-STEMMED CYPERUS. Mootha, HIND.

Very common in low grounds: the small fragrant tubers are used in washing the hair. There are several other varieties: one of the most common is "naga-mootha," the root of which is used in the same way.—*Genl. Med. Top. p.* 174.

(3079) CYPERUS ROTUNDUS, (round).
Mootha, BENG.

Roots (rhizomes) in ovoid bulbs, the size of a pigeon's egg, united by a long woody tracing radicle, of leafy texture. Its properties are the same as those of C. Juncifolius.—*O'Shaughnessy, p.* 628.

(3080) CYPERUS, SEDGE ROOT. The roots of a species of sedge are found among the vegetables, though they taste like filberts.—*Mason.*

(3081) CYPERUS TEGETUM, is used in India for mat making.—*Royle, p.* 389.

(3082) CYPRÆIDÆ, the *Cowry Family*, Cowries, or sometimes Gowries—Porcellanen of the Germans; Porcelaines (Porcelain shells), of the French, family of Marine Gasteropodus *Mollusca*, well known in commerce from one of the species (*C. Moneta*) being used in some parts of the East as a circulating medium.—*Engl. Cyc. page* 281.

(3083) CYPRESS. A forest tree, a native of the south-eastern parts of Europe, particularly of Italy; Mexico, and the southern parts of N. America. The wood is hard, elastic, strong, resists worms, and its odour repels insects from whatever may be contained in a cabinet or chest made of it. Its duration is very considerable, but the precise period to which the tree lives has not been clearly ascertained. In some countries this tree is planted over the graves of the dead as an emblem of immortality. There are several species of this class of evergreen trees.

(3084) CYPRINIDÆ, a family of Fishes of the section *Malacopterygii Abdominales*, the species of which are distinguished by their having the mouth small.—*Engl. Cyc. page* 219.

(3085) CYPRINUS VAR.
Sayl kunde, TAM. | Sayl Duk Tambara, MALAY. | *Ain's Mat. Med. p.* 156.

(3086) CYPRUS VINE. Ipomea quamoclit.

(3087) CYTISUS ARGENTEUS, LEGUMINOSÆ.—These species are mostly hardy trees or shrubs found all over Europe, the trees mostly bearing flowers of a yellow colour, with a few exceptions of white and purple, they are readily increased by seed, layers, or buds.

(3088) CYTISUS CAJAN. Syn. Cajanus indicus.
Urbur, HIND.

One of the woods employed in the Bengal powder works at Eshapore, in the manufacture of Charcoal. It might be probably employed in the manufacture of Pyroligneous Acetic acid.—*Beng. Phar. p.* 235.

D

(3089) DAB OR KOOSHA, Poa Cynosuroides, is the sacred grass of the Hindoos, and is made into rope in north Western India.

(3090) DACCA, possesses a variety of articles of Agricultural produce, as Rice, Pulse, Millet, Maize, Cotton, Safflower, Indigo, Sugar, Ginger, Coffee and Capsicum, but only two of these, viz., Cotton and Safflower are raised in greater perfection there than elsewhere; and may therefore be considered as staples peculiar to the district. The indigenous Cotton of Dacca has long been celebrated for its superior quality. It is cultivated along the banks of the Megna from Feringybazar to Edilpore in Backergunge, a distance of about forty miles; on the banks of the Brahmaputra Creek (the ancient channel of the river of the same name) and along the Luckia and Banar. It presents different shades of quality, the finest of which is named *photee*, and is the material of which the delicate Muslins are made. It is described by Roxburgh, as differing from the common Herbaceous Cotton Plant of Bengal in several particulars, but chiefly in having a longer, finer and softer fibre than it. Safflower (Carthamus tinctorius) now so extensively used for dyeing silks in England and France, is one of the most valuable agricultural products of the district. Next to fine muslins, and embroidered fabrics, silver filigree work is that for which Dacca is most celebrated. This art is also practised in great perfection at Cuttack, and in Sumatra, and China. The articles usually made at Dacca are Ladies' Ornaments, such as Bracelets, Ear-rings, Brooches, Chains, Necklaces, &c. and *Attar-dans* and small boxes for natives. A specimen on a large scale could be made, such as a vase for flowers, a stand for writing materials. The design best adapted for displaying the delicate work of filigree is that of a leaf. It should be drawn on stout paper, and of the exact size of the article intended to be made. The apparatus used in the art is exceedingly simple, consisting merely of a few small crucibles, a piece of bamboo for a blow pipe, small hammers for flattening the wire, and sets of a forceps for inter-twisting it. The drawing of silver and gold (*i. e.* silver covered with gold) wire, used as thread in embroidery, is extensively carried on here. Benares is also celebrated for this art. There are several varieties of silver and gold thread (*badla*) made at Dacca,

as *goolabutoon* for the embroidery of muslins and silks; *goshoo* for caps and covering the handles of chowries; *subnah* for turbans, slippers, and hookah snakes; and *boolun* for gold lace and brocades. Some of it is drawn almost as fine as a hair. In the time of Aurungzebe a quantity of this article was made yearly for the Court at Delhi. A hundred sticks covered with it, and plain gold, and silver *badla* to the amount of £2,000 in value, appear among the items composing the Mulboos Khas *Nuzr*, which was annually sent to the Emperor.—*Dr. Taylor.*

(3091) DACTYLOPTERUS (Lacépède), a genus of Fishes belonging to the order *Acanthopterygii* and family *Loricati*. It has the following characters:—Head flattened, large, and long and rising suddenly from the muzzle, which is very short; inferior angle of the pre-operculum furnished with an elongated strong spine; operculum without spines; mouth small; jaws furnished with masses of minute conical teeth; branchiostegous rays six in number; some of the anterior rays of the dorsal fin free; subpectoral rays numerous, very long, and connected by a membrane; ventral fins with four rays; body covered with hard carinated scales. This genus contains but two species, one of which has been long known: it inhabits the Mediterranean, and is the *Trigla volitans* of Linnæus. It is commonly called the Flying-Gurnard and Flying-Fish; but there are other species of fish which have obtained this name, on account of their power of sustaining themselves for a few seconds out of the water. The other species inhabits the Indian Seas, and is the *Dactylopterus orientalis* of Cuvier.—*Eng. Cyc. p.* 297.

(3092) DÆMIA EXTENSA. The Ootrum fibre, is a promising substitute for Flax, which, in the Madras Exhibition of 1855, was exhibited by Captain Meadows Taylor. The Ootrum fibre of the Nizam's Territories is soft, white, silky, and strong: it can be procured in considerable quantities in Southern India, the Dæmia extensa being a common creeper belonging to the Asclepiadaceæ. Capt. Meadows Taylor exhibited good specimens of this and of six other fibres suited for cordage and weaving, and the Jury awarded a 2nd Class Medal for these specimens. —*M. E. Jur. Rep.*

(3093) DAHLIA VARIABILIS. COMPOSITÆ. This flower is a native of Mexico, and grows there in a sandy soil. It was first introduced into England in the year 1789, and into India about 20 years ago. It is now very common in all parts, and, from its great diversity of colour, is generally cultivated with much care, especially by Europeans. The leading varieties of the fertile rayed are—purple, rose, pale white, yellow, yellow and orange, pale yellow, light blue, dark red, &c. Flowers single. Of the barren rayed species, there are the scarlet, bright scarlet, orange, saffron and yellow flowered, single, semi-double, and double, and several sub-varieties. It is propagated by dividing the roots and cuttings for ordinary purposes, and by seed for new varieties. If the tubers are cut, be careful to preserve an eye in the part, otherwise it will throw out root fibres but no shoots. If seed is to be preserved, remove all the tubers carefully so that the nourishment may be given to the flower: and if to produce tubers for the following season, remove the flowers when early in bud, after having ascertained the colour. The finest double species are grown in this manner, though you may occasionally get a double flower from seed. The method by which favorite sorts may be increased is as follows. The old tubers are to be placed in a large flower pot of good leaf mould and old manure, leaving the crowns only exposed. The shoots which quickly rise from the tubers are cut or clipped off, when about two or three inches in length, and put into fresh pots, or in a bed, where they must be carefully watered, and shaded until they have struck and taken root, when they will grow vigorously. Tubers that have no eyes near the crown should be rejected. If grown from seed, the plant should be removed when about four or six inches high, and if placed in the ground, a space of two feet at least between each plant allowed; and as the plant arrives at maturity, it must be supported by strong sticks. When the stalk has become dry, the tubers may be removed and kept in a room, either upon sand or pounded charcoal. The plants should have all the lower straggling branches removed with a sharp knife, and so trained that, when in blossom, the flowers may appear to the greatest advantage. The soil should be a light rich loam, mixed with sand. The tubers may be left in the ground, but it is not safe to do so, rats and other vermin being destructive to them.—*Riddell.* The original species were single, the double flowers owe their origin to cultivation. They require a free soil, not too rich, and owing to the rapid degeneration of the flowers on the plains, they would require to be yearly introduced from England. The culture ought to be regulated so as to get them in flower after the heavy rains are past, and they require to be shaded from the mid-day sun. After flowering, they should be cut down and the roots preserved in pots of sand in a dry place as cool as possible. When they start to grow the following season, if preserved, they should be gently watered for a few days, retaining them in the pots of sand. When the shoots are about half an inch long, the roots should be divided with a sharp knife leaving one or two eyes to each division, in a week they may be transplanted into separate pots about 4½ inches wide, after the pots are filled with roots they should be repotted into pots in which they are intended to flower; after growing some size

let them be neatly staked, taking care not to injure the roots.—*Jaffrey.*

(3094) DAISY, OR DAY'S EYE, the little perennial plant called *Bellis perennis* by botanists. Like most composite flowers, it has proved productive of varieties when domesticated; but they have almost disappeared, except from old-fashioned or cottage gardens.—*Eng. Cyc. p.* 298. In India, this plant and its varieties seldom live through the hot season, and do not remunerate for the trouble taken to raise them, unless required as a "Souvenir" of home. They are easily raised from seeds sown during the rains. Natives of Britain and Italy.—*Jaffrey.*

(3095) DALBERGIA, a genus of Plants belonging to the natural order *Fabaceæ*, named in honour of Nicholas Dalberg, a Swedish botanist. It has a campanulate calyx, 5-toothed; a papilionaceous corolla, the petals of the keel connected to the apex; 8-10 stamens, sometimes all monadelphous, with the tube or sheath cleft in front, sometimes divided into two equal opposite bundles. It has a stipitate membranous compressed legume, which is flat, oblong, and tapers to both ends. The seeds, which vary from 1 to 3, are compressed and remote. The species are sometimes trees, but usually climbing shrubs, with impari-pinnate leaves. There are about 22 species of this genus, none of which are of any known use except those mentioned.—*Engl. Cyc. p.* 298. Dr. Wight gives Dalbergia frondosa, 266; latifolia, 1156; marginata, 87; Oogeinensis, 391; reniformis, 261; rimosa, 262; robusta, 244; scandens, 275; stipulata, 243; tamarindifolia, 242; Dr. McClelland mentions that in Tenasserim, there are four kinds of *Dalbergia Black woods*, Yindike, *Burm.* all yielding a heavy timber, which will not float, similar to Sissoo. These trees are very plentiful in the Tharawaddy and Hlaine districts, also in the lower parts of the Toungboo district. The timber seldom attains a very large size and is generally found of a girth of three or four feet. Wood, black.—*McClelland.* One of the genus Dalbergia, is known in Tenasserim as the Chisel-Handle Tree. It is a common forest tree produces a hard, fine-grained wood which the Karens call the egg tree, and the Burmese the chisel-handle tree, its wood being much used for chisel handles. Mr. Mason has not seen the flower, but the fruit identifies it with Roxburgh's genus.—*Mason.* There is another large timber tree of the genus Dalbergia found throughout the Provinces, sometimes wrought into canoes, which he thinks is a species of dalbergia, but he has never seen it in flower. It is the tree of which, according to Burman geography, there is an immense specimen growing on the Great Eastern Island.—*Mason.*

(3096) DALBERGIA ACUMINATA, Rottl.

Sessoo tree Sesso, HIND. | Sissa, CAN.

Sissoo is the Hindoostani name of a very valuable wood which grows in Bahar, Oude, and Canara, and is employed for making the knees and frames of ships. In Canarese the name of the Dalbergia acuminata is Sissa.—*Ains. Mat. Med. p.* 210.

(3097) DALBERGIA ARBOREA. WOODY DALBERGIA. Willd.

Poongamarum, TAM | Kuring jhar, HIND.
Kurrunje Ka jar, DUK. | Poongum tree, ENG.
Canaga, CAN. | Kurrunjie, SANS.
Kanoogamanoo, TEL.

The Vytians use the juice of the fresh root of this beautiful tree for the purpose of cleaning foul ulcers. A fixed oil is prepared from the seed of the legume used for burning in lamps and which is also said to possess virtues as an external application in Rheumatic affections. The poongamarum is the Caju Galedupa of Rumphius. See Vol. ii. page 59.—*Ains. Mat. Med. p.* 103. Dalbergia arborea, is a large tree with light green foliage, deciduous at the end of the cold season, the wood is light and firm and serves for common purposes, the seeds yield an useful oil.

(3098) DALBERGIA LATIFOLIA. *Leguminosæ*, Icon. 1156. Black wood.

Erooppoottoo marum, TAM. | Todigate, Vriksha, CAN.
Verugoodoocheva, TEL. | Bitti, CAN.
Sit Sal, BENG. | Sweta-shala, DUK.

This is a large tree with a thick stem, the centre and large branches of which furnish to the manufacturer, the timber generally called blackwood, it is close grained and admits of a fine polish and is therefore particularly adapted for furniture.—*Riddell.* It is from this magnificent tree, that the well known Malabar black wood is obtained, planks 4 feet broad are often procurable, after all the external white wood has been removed: it is heavy and close grained, admitting of high polish, and is very much used for furniture. It is one of the most valuable woods of the Madras Presidency.—*M. E. J. R.* This tree seems less abundant in Coimbatore than the catty marum, perhaps from being more sought after as yielding more valuable timber; it is very dark, heavy and strong, sustaining a weight of 515 lbs.—*Wight.* Mr. Rohde mentions it as one of our largest mountain trees: flowering during the wet season, seeds ripening in February and March. The wood of the centre of the trunk and large branches is what is commonly called black wood, and is used for making furniture. It is rather heavy, sinking in water, close grained and admitting the finest polish. On the Malabar Coast the tree grows to an immense size. Dr. Roxburgh has mentioned another wood, the Diospyros Ebenaster with the same Telingu name, on the Malabar Coast. Planks of three feet of black wood are obtained in the Northern Circars. It seldom exceeds 14 inches in breadth though occasionally it is met with of greater diameter.—*Rhode M.S.S.*

(3099) DALBERGIA MONETARIA, another of the species, yields a resin very similar to Dragon's Blood.—*Eng. Cyc.*

(3100) DALBERGIA PANICULATA. *Leguminosæ*, Roxb. c. 114.

Putchally wood, ENG. | Putchalai marum, TAM.

This tree attains a considerable size, but Dr. Wight is as yet unacquainted with the timber. It is said to be strong and being of considerable size, is fit for many purposes.—*Wight.*

(3101) DALBERGIA SISSOO.

Sissoo wood, ENG. | Seessoo, HIND.
Yekerecchava kurra, TEL. |

D. Sissoo, has five alternate leaflets, glabrous above, pubescent beneath. It is a native of Bengal and the adjoining provinces to the northward where the timber is much prized, and is known by the name of Sissoo.—*Eng. Cyc.* Flowering time, the beginning of the hot season; the seed ripens about the close of the year. This tree yields the Bengal ship-builders their crooked timbers and knees, it is remarkably strong, but not so durable as could be wished, it answers well for various other economical purposes, the color is a light greyish brown, with darker colored veins. Upon the whole there is scarcely a tree which deserves more attention, for when its rapid growth in almost every soil, its beauty and uses are taken into account, few trees can be compared with it. Major Campbell's estimate of the value of Sissoo in practice, of this wood, is 96, being higher than that of the best specimen of Teak. This tree attains perfection in 28 years. Many young trees are thriving well at Masulipatam, and from their appearance, Mr. Rohde should say it would thrive well in our provinces. Its rapid growth recommends it for avenues. Dr. Wallich and others have recommended it for plantations, shewing the probable return.—*Rohde M.S S.* Dalbergia sissoo was introduced into the Madras Presidency from Bengal at the recommendation of Dr. Wallich, and has been planted on the banks of the Toomboodra, where it is thriving wonderfully; it is growing extensively in the cantonment of Masulipatam, as an avenue tree, and has been planted in some places on the banks of the Kistnah Annicut. There are few trees which so much deserve attention, considering its rapid growth, its beauty and its usefulness. Wood hard, strong, tenacious, and compact, whilst its great durability combines to render it one of the most valuable timbers known. The tree grows rapidly, is propagated and reared with facility, and it early attains a good working condition of timber. It is used in Bengal for Gun Carriages. Hort. Garden 39, Bengal 84.—*M. E. J. R.* Sissoo is scarce in the hills of Ajmeer, but more abundant in Kotah. The wood of the Ajmeer tree is very dark and beautifully veined, like rose wood.—*Gen. Med. Top. p.* 203. The wood is used principally, from its strength and natural bend, for native hackeries: when it can be procured long and straight, it makes good shafts for buggies.—*Riddell.*

(3102) DALBERGIA SISSOIDES. *Leguminosæ.*

Rose wood, ENG. | Eatty or vitty marum, TAM.

This is perhaps the best known in our jungles of the trees yielding black wood, but there are several others as good or perhaps better. It abounds in the Palghaut forests, but is rarely met with now of great size; when it and its congener Dalbergia latifolia are carried to Madras it becomes one of the rose woods of the furniture shops.—*Wight.* Dalbergia sissoides, Bitty marum, kar Itty or Blackwood, is a smaller tree than D. latifolia, but more common in the forests. Both yield a black wood, and in Madras are indiscriminately called "Rose wood." The wood contains much oil, which unfits it for receiving paint.—*M. E. J. R.* Mr. Rohde says that this, the blackwood or East India Rosewood, is one of our best woods for plain furniture, though at Madras it is said to cast about a good deal; by experiment he found it to be one of the strongest timbers we have in the Circars, he is inclined to believe that the wood imported from the Western Coast is not equal in strength to the smaller but closer grained wood of the Circars, and the appearance of the latter is more veined and he thinks closer in the grain than that of the Western Coast—the wood contains much oil which renders it unfit for receiving paint—logs are almost invariably faulty in the centre: as a tough strong wood it will be found useful whether curved or straight.—*Rohde.*

(3103) DALECHAMPIA POMIFERA.

Douk-ya-mah, BURM.

Scarce, only met with on the banks of streams in the Pegu Valley, particularly in the Pymmah Choung. Wood, dark-brown.—*McClelland.* Wight gives Dalechampia. Capensis, 1881; Indica, 1882; velutina, 1881. At another place, Dr. McClelland says that *Dalichampia pomifera*, Doukyamah, *Burm.* has been found on the Pymmah Choung in the Pegu Valley. The trees are from three to four feet in girth. Wood red, adapted to cabinet making.—*McClelland.*

(3104) DAL-SHIKARA, DALCHIKARA. A crystallized salt, brought to Ajmere from Bombay; it is white and transparent, in small grains: it is very poisonous: is sometimes used in medicine; but, chiefly in "rasan" or transmutation of metals: is true bichloride of mercury, or corrosive sublimate: costs one rupee per tola.—*Gen. Med. Top. p.* 134.

(3105) DAMASK.

Damaskwerk, DUT. | Tela damaschina, IT.
Venise, FR. | Tela adamascada, SP.
Damasten Tafelzeng, GER. | Kamtschatnua salfitki, RUS.

A description of silk or linen cloth, of thick

texture, but fine quality, with figures or flowers raised on the surface. It is a twilled fabric, and is extensively manufactured at Dunfermline in Scoland, also in some parts of England and Ireland, and is used chiefly for table cloths and napkins. China damask, which is a rich flowered fabric on a crimson foundation, is composed entirely of silk, and is used in India for lining carriages, chairs, sofas, &c.—*Faulkner*. According to Mr. Tomlinson, Damask is a textile fabric, woven in a loom, variegated with figures of flowers &c. The manufacture is said to have originated at Damascus, whence the name.—*Tomlinson, p.* 488.

(3106) DAMASCUS BLADES present on their surface a variegated appearance of watering. The blade is formed by mixture in nearly equal proportions of the celebrated Wootz and soft iron which being welded together and repeatedly doubled gives the desired appearance. Daggers and sword blades thus formed are common among the retainers of the Hill Zemindars in the Northern Circars of the Peninsula of India, the handles of which, formed of iron, are frequently damascened in silver.—*Rohde M. S. S.*

(3107) DAMMER.

Dammar, ARAB.	Yakshadupha, SANS.
Dummula, CYNG.	Coongkilium, TAM.
Dummur, GUZ. & HIND.	Googhilum, TEL.
Dammar, MAL.	

A hard, chiefly dark coloured, brittle, resinous substance, which exudes from different trees growing in India, the Eastern Islands and Malayan Peninsula, from whence it is exported to India. In Bombay it is used, when melted, for spreading over packages, gutters or water courses, eaves of houses, the bottoms of sailing vessels, &c, to render them water-proof.—*Faulkner*. As it is a substance in very general use, throughout Eastern and Southern Asia, it may be well to notice the several sources from which it is obtained.

a. Country Rosin or Dammer, Coongilium, *Tam.* Raul, *Duk.* and *Hind.* Googilum, *Tel.* Damar batoo, *Malay*. Chloroxylon Dupada, Buch. Ainsie says, that of the substance usually termed Dammer by the English in India, there are three orts to be met with in the bazars called, in Tanool, vullay Coongillium; carpoo Coongillium and oray Coongillium in other words white, black, nd coarse Dammer. It much resembles the osin obtained from the pine both in appearance nd natural qualities and would seem to be ommon in many Asiatic countries, being found n great abundance in Sumatra, and in Java, on everal of the Sooloo islands and in the Malayan eninsula. There are no doubt different kinds f it some of which may be the produce of a speies of pinus. But what is usually exposed for ale in the lower provinces of Hindoostan, is ot amongst the mountains which separate ravancore from the Madras district. Dr. Buchanan first bestowed upon the tree the scientific appellation of Chloroxylon dupada an account of which may be seen in his Journey through Mysore, Canara and Malabar. Whether this tree bears any resemblance to that which produces Dammer on Amboyna, I cannot say. The reader may find a minute description of the last mentioned by referring to Rumphius, Tom, 2nd Lib. 3rd cap. 9. I shall only further observe that the Tamool name of the Indian Dammer tree is chaducula. The Malayalum appellation is payana. The black and white both grow in the district of Coimbatore, at a short distance from the town, i. e about 15 miles, at a place called Motamanspettaimulay.—*Ainslie*.

(*b*) This substance, in conjunction with wood oil, makes a useful coarse varnish for doors, windows &c. It is also sometimes employed as a pitch in Dock yards; and by the Farriers in the preparation of certain plasters. When melted with Gingilee oil, it is used for the domestic purpose of covering corks in bottles, to preserve them from the white ants.—*Ains. Mat. Med. page* 152.

c. Dammer is produced largely all along the Eastern range of Ghats from a species of Saul (Shorea Dammer, or Vatica), which affords a useful and much prized timber.

d. Dammer Googgelum, *Tel.* Goonglium, *Tam.* is also the produce of the Shorea Tambagaia Roxb. and of others of the same species. The different trees yield different species of rosin, which are designated according to their colour and consistence. One is called *damar batu* in Malay, or damar *Selo in* Java, which is a hard or strong rosin, and another in common use, *damar puteh* or white rosin, which is softer. The trees which produce the dammer yield it in amazing quantity and generally without the necessity of making incisions. It exudes through the bark, and is either found adhering to the trunk and branches in large lumps, or in masses on the ground under the trees. As these often grow near the sea side or on the banks of rivers the dammer is frequently floated away and collected in distant places as drift: It is exported in large quantities to Bengal and China, and is used for all the purposes to which we apply pitch but principally in paying the bottoms of ships.—*McCulloch's Com. Dict. Roxb.* It is prepared by boiling with oil and in the neighbourhood of the ports of peninsular India, is sold in this form under the name of *keel* in Teloogoo. It is also used boiled with wood oil as a varnish for house beams, doors &c., and by painters to render oil drying.—*Rohde M.S.S.*

e. Dammar of Bengal is the Resin of Shorea Robusta.—*Ben. Phar.* 204.

f. Damnar—White, occurs in fragments of variable size, marked with reddish streaks, transparent, amber-like, brittle, with brilliant fracture,

very inflammable, inodorous, and tasteless. This resin flows from the *Pinus dammara*, which grows on the lofty mountains of Amboyna. It hangs from the branches, and resembles stalactites, the pieces being sometimes as large as the hand, and 4 to 8 inches long; some pieces are like *animi* resin. The dammar of the Bengal bazars is usually the produce of the *Shorea robusta*.—*O'Shaughnessy, p.* 617.

g. Dammer in India supplies the place of pitch and rosin, and in the Tenasserim Provinces is the product of three different genera, belonging to the wood oil tree family—the shorea, the hopea, and the dipterocarpus.—*Mason.*

h. Dammer, Pwai-ngyet, *Burm.* is found in the bazars throughout Pegu. It is yielded by the *Shorea robusta*, or the Saul-tree of India, which occurs plentifully in the Forests on the Shan side of the Sitang, east of Tounghoo, and also, but to less extent, in the forests of the Prome district. I have not found however that the dammer is obtained from these forests, as none of the trees appear to have been perforated for it, so that the supplies of this article are probably brought down to Pegu from forests beyond the frontier.—*McClelland.*

i. Dammer or Dammar of China and Eastern Archipelago, is a kind of indurated pitch flowing spontaneously from several species of pine in the Indian islands; there is a hard sort, and a white, softer kind. It is found in large lumps, both under the trees and on their trunks, and in large quantities. It is mixed with a softer kind which makes it less brittle; and is then used for closing seams in boats, and other wooden vessels. As it is seldom brought to China except in native vessels, there is no means of ascertaining the amount, but it is probably not very large. It can be obtained in Borneo for 50 cents per pecul.—*Compendious Description.* The meaning of this word in Malay and Javanese is "resin." The substance usually known under this name is the produce of several forest trees, and is the sap which exudes spontaneously, and being exposed to the air acquires a flinty hardness from which the epithet batu, or stone, is given to it to distinguish it from a softer substance, kruin or wood oil. The damar is found either in larger masses at the foot of the trees which yield it, or floating in rivers, drifted to them by the floods of the rainy season. It is produced in such abundance, and gathered with so little labour, that its market price seldom exceeds four or five shillings a hundred weight. The natives of the country apply it to most of the uses to which we put tar, pitch, and resin, and it forms an article of exportation to Continental India. Most of the family of Dipterocarpeæ yield resinous balsamic juices, those of the genus Dipterocarpus, the wood-oil, and of Vateria, indurated damar. The natural order abounds in Sumatra, Java, and Borneo, which are the chief sources of the dammar of commerce.—*Crawfurd Dictionary, page* 118.

(3108) DAOUD MURDAN, LEAVES OF, are the Leaves of Cassia alata.

(3109) DAPHNE, a genus of Plants belonging to the natural order *Thymelaceæ*, containing many species, inhabiting the more temperate parts of Europe and Asia. Among them some are cultivated in gardens for their beauty or fragrance, others are of medicinal importance, and a few are employed in the manufacture of hemp and paper. We shall briefly notice the more remarkable of these. The genus *Daphne* is distinguished in its natural order by having 8 or 10 stamens inclosed within the calyx, a simple stigma, a succulent fruit, and a calyx, the orifice of whose tube is destitute of appendages. In addition to the acrid and dangerous properties which appear to be common to them all, some species are remarkable for the toughness of their fibre, and for the economical purposes to which they are applied. From *D. Cannabina* is prepared the best kind of writing-paper in China, according to Loureiro; but it must be observed that this statement, if true, is at variance with what is observed in Nepaul, where the daphne-paper is very brittle and bad.—*Eng. Cyc. p.* 309.

(3110) DAPHNE CANNABINA (THYMELÆE), NEPAL PAPER PLANT. At the Great Exhibition of 1851, many were much interested about a huge sheet of Nepal paper exhibited by Col. Sykes. This was curious, not only on account of its size, but also on account of the plant from which it was made. This belongs to a genus and family containing plants remarkable for their fibrous bark. Thus the Lace-bark tree (*Daphne Lagetta*, now *Lagetta lintearia*) of the West Indies is "remarkable for the beautiful net-like appearance of its several easily separable layers of bark, whence it has received its English name. As the fibres of other species possess considerable tenacity, they have been employed in making cordage; and the toughness, as well as fineness of the inner bark of these plants, may be seen in a plant common in English gardens, and used in medicine on account of its acridity, that is, the Mezereon, *Daphne Mezereum* of botanists. It is from the inner bark of one of these plants, the *D. Bholua* (*D. cannabina* of Loureiro, and which is supposed to be identical with the *D. odora* of Thumberg), which is extremely abundant in the Himalayas, that this Nepal paper is made, as from other species in other countries. Another plant of the same, or of an allied genus, as it is called both *Daphne* and *Gnidia eriocephala*, is very common on the ghauts of the West of India, and in the hilly parts of the Southern Mahratta country and of the Dukhun. Several specimens

from various localities, are in Col. Sykes's collection. It is probable that it might be turned to the same use as the Nepal plant. Of the uses of this plant good accounts have been given by Mr. Hodgson ('Journ. As. Soc.,' i, p. 8, 1832) and Dr. Campbell. The former describes the process as consisting, first, in boiling slips of the inner bark of the paper plant in a lay of wood-ashes for about half an hour, by which time the slips will be quite soft. These are then beaten in a mortar with a wooden mallet till they are reduced to a homogeneous pulp. This is then diffused through water, and taken up in sieves and paper frames, as in the ordinary process for making paper by hand. When dry, the sheet of paper is folded up; sometimes it is smoothed and polished by being rubbed on wood with the convex side of a conch shell: but Mr. Hodgson does not explain how the very large sheets of several yards square are made. Though called Nepalese, the paper is not manufactured in Nepal, but in Cis-Himalayan Bhote, in the midst of its immense forests, where there is an abundant supply of the plant, of wood for ashes and for firewood, as well as a constant supply of clean water. This paper is remarkable for its toughness, as well as its smoothness. Some of it, in the form of bricks of half-stuff, was sent to England previous to the year 1829. As the quantity sent was not sufficient to the complete experiment, a small portion of it was made into paper by hand. An engraver, to whom it was given for trial, stated that "it affords finer impressions than any English-made paper, and nearly as good as the fine Chinese paper which is employed for what are called India paper proofs." ('Gleanings in Science,' i, p. 210.) Dr. Campbell describes the paper, as made by the Bhoteahs, "as strong, and durable as leather almost, and quite smooth enough to write on; and for office records, incomparably better than any India paper. It is occasionally poisoned by being washed with preparations of arsenic, in order to prevent the destruction caused by insects. Many of the books in Nepal, written on this paper, are said to be of considerable age, and the art of making paper seems to have been introduced about 500 years ago from China, and not from India." He states that this paper may easily be procured at Patna, Purneah, and other places in the plains of both Southern and North-Western India.—*Royle, Fib. Plants, p.* 311. The dried bark, of the Nepaul paper plant, may be substituted for the Mezereon (D. Mezereum) of the London Pharmacopeia. The bazar mezereon is almost always inert from age.—*Beng. Phar. page* 279.

(3111) DAPHNE GNIDIUM, the Garou-Bush, an evergreen with narrow sharp-pointed erect light-green leaves, and branching clusters of white fragrant flowers, is a common plant in dry waste places in the south of Europe. It will not live in the open air in England, except in the warmest counties. Both the berries and leaves are employed by the French as purgatives. The plant also affords a good yellow dye.—*Eng. Cyc. p.* 399. Honigberger says that the bark of the Spurge-Flax (Daphne Gnidium) introduced into the ears produces a serous discharge, macerated (steeped) in vinegar for about an hour before using it and afterwards applied (renewing it in winter once, in summer twice a day) is said to produce a local serous exudation without excessive irritation or blistering and is recommended chiefly in chronic rheumatism, gouty affections, paralysis, &c. In France and Russia it is used, in Ophthalmia. May not Sunnerkat from Cashmere have similar properties?

(3112) DAPHNE LAGETTA, the Lace-Bark-Tree of Jamaica, is most remarkable for the tenacity of the fibre of which its bark consists, and for the facility with which it may first be separated into thin layers and then into distinct meshes. If the inner bark of this plant be macerated in water it may be readily separated into layers no thicker than the finest lace, and which, after having been pulled a little sideways, resembles in some measure that fabric. King Charles II. is said to have had a cravat, frill, and ruffles of Lace-Bark presented to him by his governor of Jamaica.—*Engl. Cyc. page* 300.

(3113) DAPHNE MEZEREUM. MEZEREON.

Mazrioon. PERS. | Kameela, GREEK.

The effects of daphnine on the animal economy are not ascertained, but deserve accurate trial. It has been found in every species of Daphne yet analysed. The berries of Mezereon are brisk but unsafe cathartics. Fresh Mezereon bark is much used as a counter-irritant and external stimulant; the dried bark is given internally in small doses as a stimulant alterative in syphilitic, rheumatic, and scrofulous maladies. The usual dose is 10 grs. infused in 2 oz. of water. It is more frequently combined with sarsaparilla, as in the Lisbon diet drink.—*O'Shaughnessy, page* 530. A Daphne grows in the Cashmerian mountains. The specimen from Cashmere, not having the flower, the botanists of Vienna could not decide upon it further than that it is allied to Daphne gnidium and Daphne oleoides. It is essentially different from Daphne cannabina, from which, in Nepaul, a paper is manufactured, according to the Chinese manner. (V. B. Disp. p. 531.)—*Honigberger, p.* 268.

(3114) DARCHEENEE. LAURUS CINNAMOMUM.

(3115) DARJELING RIDGE varies in height from 6500 to 7500 feet above the level of the sea; 8000 feet being the elevation at which the mean temperature most nearly coincides with that of London, viz., 50°.—*Hooker Him. Jour. Vol.* i. *p.* 115. To the north-west, towards Nepal, the snowy peaks of Kubra and Junnoo (res-

pectively 24,005 feet and 25,312 feet) rise over the shoulder of Singalelah; whilst eastward the snowy mountains appear to form an unbroken range, trending north-east to the great mass of Donkia (23,176 feet) and thence south-east by the fingered peaks of Tunkola and the silver cone of Chola, (17,320 feet) gradually sinking into the Bhotan mountains at Gipmoochi (14,509 feet.)—*Hooker Him. Jour. Vol.* i. *p.* 123.

(3116) DAROO. The general term for ardent spirits. The spirit called Daroo distilled from the flower of the Mawa is produced in great quantities in all the jungles of the upper Godavery. It resembles whiskey in taste.

(3117) DARNEL, BEARDED OR POISONOUS DARNEL, Lolium temulentum, occasionally becomes mixed in Europe with the flour of wheat or some other cereal farina and has occasioned many painful symptoms.—*Hassell.*

(3118) DARNING (*rufu-gari*) is a branch of the sewing art which, though in Europe applied to the most homely purposes, requires the greatest skill in the East, where a defect in a costly shawl is to be made good, or a coarse thread is to be picked out of a piece of a muslin into which it has been accidentally introduced. So skilful are some of the *rafugars*, that they can extract a thread twenty yards long from a piece of the finest muslin, and replace it with one of the finest quality. They are principally employed in repairing the muslins and calicoes that are injured during bleaching, in removing knots and joining broken threads; also in forming the gold and silver headings on cloths."—*Taylor. Royle Arts &c. of India, page* 505.

(3119) DARUN-AJ-AKARBI. A kind of fern: the root and leaves of which come to Ajmeer from Arabia via Bombay: considered as a tonic: four to six massee are a dose: one tola costs two rupees.—*Gen. Med. Top. p.* 133.

(3120) DATE TREE. PHŒNIX DACTYLIFERA.

(3121) DATES, DRIED.

Kharack, GUZ. HIND. | Kharack, PERS.

As the name implies, are simply fresh dates dried in the sun. They have a shrivelled appearance, and a pleasant subacid taste. They are brought to Bombay from the Arabian Gulf. —*Faulkner.*

(3122) DATES, WET.

Dattes, FR.	Datteri, IT.
Datteln, GER.	Khurma, PERS.
Kajoor, GUZ. & HIND.	Dattiles, SP.

The fruit of the date-palm of which there are upwards of a hundred varieties, but in general the date may be described as acorn shaped, composed of a thin glossy membrane, which contains a fine, soft, and pulpy fruit, that is firm, sweet, and rather vinous to the taste; within this is enclosed a solid, tough, kernel. A considerable part of the inhabitants of Egypt, Arabia, and Persia, subsist almost entirely on this fruit. Dates are largely imported into Bombay, from the Arabian Gulf, a large portion of which is re-exported to Calcutta, the Mauritius, and other places.—*Faulkner.*

(3123) DATISCA CANNABINA. IKL-BEER, grows in Cashmere, Kouawur, Nepal, and in the Himalayas, is much esteemed in the Punjab for dyeing silk of a yellow colour.

(3124) DATUNI. This is the root of the "junalgota" plant Croton tiglium, and is brought to Ajmere from Delhi and Pali: it is a very powerful purge much used in prescriptions: one seer costs four rupees.—*Gen. Med. Top p.* 133.

(3125) DATURA, a genus of Solanaceous Plants, with a funnel-shaped angular 5-lobed calyx, a corolla of a similar form, but much larger, and a 4-celled capsule, which is either smooth or muricated externally; the base of the calyx moreover adheres to the seed-vessel in the form of a circular disc. Several species of this genus are known in cultivation, the very large size of their funnel-shaped flowers rendering them conspicuous objects; they have however a nauseous odour, and are only handsome when in flower, for which reason they are not general favorites. —*Eng. Cyc. p.* 299. The Datura is cultivated in gardens, the colours of the flowers are white, yellow, purple and blue. They are easily cultivated from seed, common all over India. Wight figures Datura alba, 852; fastuosa, 1396; metel, 852; stramonium, 1396.

(3126) DATURA FASTUOSA (Kala dhatoora) and *alba* (Sada dhatoora) are very common over the peninsula of India, and are also called *Jouz mazil*, or methel, (Royle) the seeds being frequently used as a poison. For the purpose of facilitating theft, and other criminal designs, the seeds are given in Bengal with sweetmeats to stupify merely, but not with the intention of killing; intoxication or delirium is seldom produced, the individual sinks into profound lethargy resembling coma, with dilated pupils, but natural respiration. These symptoms have been known to continue even for two days, and still recovery take place; cold affusion and strong stimulant emetics constitute the most effectual treatment. The vision often continues obscured long after the general recovery takes place. This state is best remedied by blisters to the temples or nape of the neck, and by cold affusion. If given while the stomach is empty a much smaller dose may induce all the preceding symptoms, and prove fatal. This is well known to the Indian poisoners, who suit the time of administration according to the purpose they mean to serve. *Purple flowered thorn apple.* Both the single and double flowered varieties of this species may be often seen near Burman houses, and children

not knowing its poisonous character, sometimes eat the fruit with very serious effects.—*Masson.*

(3127) DATURA METEL. DATURA ALBA. The white thorn apple. The white datura has little to recommend it in point of beauty, or pleasantness of association, yet we find it celebrated by Heber in his "Walk in Bengal."

> "While to the cooler air confest
> The broad datura bares her breast,
> Of fragrant scent, and virgin white,
> A pearl around the locks of night."

It is often seen blooming around native dwellings, and may possibly be used in Tenasserim for the same bloody purposes as in India. The common stramonium of Europe and America "is perhaps only a variety."—*Mason.*

(3128) DATURA PONTICA. One of the plants which is reputed to have contributed to the poisonous quality of the honey that was eaten by Xenophon's soldiers, is very like this species, and is often cultivated as a hardy evergreen.—*Engl. Cyc. page* 299.

(3129) DATURA STRAMONIUM. Thorn apple. Datoora, *Beng.* (applied to other species.) A native of waste places all over Europe. A bushy, smooth, fœtid annual, 2 to 3 feet high, stem much branched. The narcotic properties of stramonium have been proved by Lindberger and others to correspond exactly with those of the belladonna and hyoscyamus; an alkaline principle has been separated from the seeds by Runge and other chemists, which so closely agrees with atropia in all its proprieties that the general opinion regards them as identical.—*O'Shaughnessy, p.* 468. *Medicinal uses.* The alcoholic extract of the seeds of the stramonium is a perfect substitute for belladonna for many of the purposes described under that head.—*O'Sh., p.* 469.

(3130) DATURA TATULA. A native of North America, very nearly the same as D. Stramonium, but is a larger plant with purple stems, and the corolla similarly stained at its edges.—*O'Shaughnessy, p.* 469.

(3131) DATURIA. Dr. O'Shaughnessy introduced this preparation which can be readily and cheaply made in Bengal, as a substitute for the Extract of Belladonna of the European Pharmacopeia. One grain of neutral sulphate of daturia dissolved in one ounce of water affords a solution, two drops of which introduced into the eye will occasion immediate dilation of the pupil. It seems to be a perfect substitute for the Belladonna.—*Ben. Phar. page* 266.

(3132) DAUBENTONIA. *Leguminosæ.*—DAUBENTONIA PUNICEA.—Handsome plants brought from South America, closely allied to the Piscidia. Grow well in a sandy loam.

(3133) DAUCUS CAROTA. Lin.

Carrot kalung, TAM.	Canjara, SANS.
Gajur, DUK. and HIND.	Carrot, ENG.

This is cultivated in great abundance in Mysore, and in some of the Mahratta countries where it grows of a superior quality.—*Ainslie, p.* 237.

Daucus Carota (Gajra, *Hind.*) is now cultivated all over India; fruit fleshy; smell feebly aromatic, taste sugary and mucilaginous. Poultices of the rasped root are much used for correcting fœtid discharges from sloughing sores. The seeds are stimulating, and reputed to be diuretic: like the fruits of most of this order, they yield essential oil.—*O'Sh., page* 368.

(3134) DEALS.

Dœler, DAN.	Tavole, Piane, IT.
Deelen, DUT.	Tarcice, POL.
Planches minces, FR.	Doski, RUS.
Dielen, GER.	Tiljor, SW.

A thin kind of fir plank, much used in carpentry. They are formed by sawing the trunk of a fir tree into longitudinal divisions of greater or less thickness, according to the purposes they are intended to serve. They are obtained from Dantzic, Petersburgh, Narva, North America, &c. Those procurable in Bombay are chiefly imported from America.—*Faulkner.*

(3135) DECAISNEA. This is a very remarkable plant, which Dr. Hooker had seen in flower in the Lachen valley, called "Loodooma" by the Bhoteeas, and "Nomorchi" by Lepchas. It grew on the ridge near Tumloong and the Ryott valley at 7000 feet; it bears a yellow fruit like short cucumbers, full of a soft, sweet, milky pulp, and large black seeds; it belongs to a new genus, allied to *Stauntonia*, of which two Himalayan kinds produce similar, but less agreeable edible fruits ("Kole-pot" Lepcha.) Dr. Thomson and Dr. Hooker in their "Flora Indica" have proposed the name Decaisnea for the genus (in honor of Professor J. Decaisne, the eminent French botanist). It has several straight, stick-like, erect branches from the root which bear spreading pinnated leaves, two feet long, standing out horizontally. The flowers are unisexual, green, and in racemes, and the fruits, of which two or three grow together, are about four inches long, and one in diameter. All the other plants of the natural order to which it belongs, are climbers.—*Hooker Him. Jour. Vol.* ii. *page* 198.

(3136) DECASCHISTIA CROTONIFOLIA, exhibited by Mr. Jaffrey at the Madras Exhibition of 1855, appears to yield a good fibre. It is to be regretted that no samples of Nettle fibre, Urtica or Boehmeria, have been contributed, as it is known that these abound on the Neilgherries, and other localities, and that they yield a long and silky fibre like the true Rheea or China grass. The *Girardinia Leschenaultiana* figured by Wight (Icon. t. 1976), is

frequent all over the higher range of the Neilgherries, the bark yields a fine strong white flax-like fibre, which the Hill people obtain by plunging the plant in hot water to deprive it of its virulently stinging properties, and then peeling the stalks. The textile material so prepared is of great strength, and the Todawars use it as thread.—*M. E. J. R.*

(3137) DELFT, DELF.

Delfs porcelyn, DUT.	Fayence Unachtes Porzellan, GER.
Faience, FR.	

A term applied to a coarse kind of porcelain, originally manufactured at Delft, whence its name. Since the improvements introduced into the English potteries by Wedgewood, it is no longer a place of any note.—*Faulkner.*

(3138) DELIMA SARMENTOSA. DILLENIACEÆ. A shrub with small white flowers in panicles.—*Riddell.*

(3139) DELPHINIUM. Several species of Delphinium occur in the Himalayas, and have been described by Prof. Royle in his work on the Botany of these regions.—*O'Shaughnessy.*

(3140) DELPHINIUM AJACIS, LARKSPUR. (Na-furman, *Hind*), is cultivated in gardens in India during the cold season (Royle). The properties of the seeds doubtless agree with those of the stavesacre kind.—*O'Shaughnessy, page* 169. The Larkspur is grown very commonly by the natives after the rains, colour a deep blue on a spiral stem. There are many species, all of which are easily grown from seed, the natives are in the habit of sowing the seed under peach and orange trees. When grown in beds, and the flowers of one colour, they have a showy and pretty appearance: a space of six inches should be allowed between each plant.

(3141) DELPHINIUM GLACIALE, of East Nepaul, smells strongly and disagreably, of musk, It is one of the most alpine plants in the world, growing at an elevation of 17000 feet.—*Hooker Him Jour. p.* 269. *Delphinium glaciale* was found abundant in the valley of the Chomiochoo near Tungu, in Thibet, and exhaling a rank smell of musk. This is a new species and has been described for the "Flora Indica" of Drs. Thomson and Hooker: it is a remarkable plant, very closely resembling, and as it were representing, the *D. Brunonianum* of the Western Himalaya. The latter plant smells powerfully of musk, but not so disagreeably as this does.—*Hooker Him. Jour. Vol.* ii. *page* 95.

(3142) DELPHINIUM PAUCIFLORUM. Nirbisi is a tuberous root, without poisonous properties. The name is applied in Sirmoor to the Delphinium pauciflorum. The best article however comes from Lahore.—*O'Shaughnessy, p.* 167 *and* 168.

(3143) DELPHINIUM STAPHISAGRIA. Stavesacre or Louse-wort. This is a biennial plant, a native of the Levant, Teneriffe, and Asia Minor. The seeds are irregularly triangular, blackish on the outside, yellowish within, of a very nauseous, bitter, and acrid taste, and heavy smell. Reduced to powder and taken internally in small doses, they act as a violent cathartic and emetic, and so uncertainly, that they are now never administered. Reduced to powder and made into an ointment in the usual way, this seed is still used as an external application, especially for destroying vermin in the hair. The seeds are also used in the Levant for intoxicating fish.—*O'Shaughnessy, page* 168.

(3144) DENDENG. The Malay name for the jerked beef of commerce, that is, of animal muscular fibre, preserved by drying in the sun, nearly the only mode of curing flesh in the Archipelago. Dendeng is made of the flesh of deer, oxen, and buffalos, and by the Chinese of that of the wild hog. It is a considerable article of native trade.—*Crawfurd Dict. page* 120.

(3145) DENDROBIUM, an extensive genus of East Indian Epiphytical Plants, found in the whole of the damp tropical parts of Asia, and a little beyond the tropics in Japan and Australia, but unknown in the rest of the world. Above a hundred species are enumerated by systematic writers: *D. Pierardi, D. cucullatum, D. chrysanthum, D. aureum, D. fimbriatum, D. moschatum, D. densiflorum, D. pulchellum, D nobile,* and a few more, are known in the collections of England.—*Eng. Cyc. p.* 304. Dr. Wight, in Icones, gives Dendrobium album, 1645; alpestre, 1643; aureum, 1646; barbatulum, 910; denudans, 1643; filiforme, 1642; graminifolium, 1649; Heyneanum, 909; humilis, 1643; Jerdonianum, 1644; macrostachyum, 1647; Pierardi, 908, and ramosissimum, 1648.

(3146) DENDROBIUM AGGREGATUM. YELLOW DENDROBIUM. Two pretty yellow flowered species of dendrobium are more rare than the purple, but they are not uncommon in the Karen jungles.—*Mason.*

(3147) DENDROBIUM ALBUM. A parasitic flower in white racemes.—*Riddell.*

(3148) DENDROBIUM CRETACEUM. WHITE DENDROBIUM. A species with a small snowy flower is very abundant, but has less to recommend it than either of the preceding.—*Mason.*

(3149) DENDROBIUM FORMOSUM. CHARMING DENDROBIUM. The genus dendrobium furnishes fifteen or more known species of air plants on the Tenasserim Coast. The one considered most interesting, botanists have named the "charming dendrobium," the flowers of which are white, with a yellow lip, three or four inches in diameter, and exquisitely fragrant. It is a choice flower with the Burmese, and grows naturally and luxuriantly in the environs of

Maulmain. Roxburgh mentions April and May as the time of flowering, but the plant blossoms in March, and the flowers are brought into town throughout the whole rains down to the close of October. Indeed it may be seen whitening under the emerald foliage of the groves nearly six months of the year. The Burmese call it the "silver flower."—*Mason.*

(3150) DENDROBIUM [illegible]ERARDI. A parasite; caulescent, st[illegible]less, from six to twelve inches long; round jointed; flowers, several towards the top of the stem, of a light rose colour.—*Riddell.* This species grows in the Tenasserim Provinces.—*Mason.*

(3151) DENDROBIUM SECUNDEM. PURPLE DENDROBIUM. A species of dendrobium with small purple flowers, the lip tinged with orange, is seen garnishing the mango trees in the neighbourhood of Maulmain. The flowers are peculiar, being in long racemes all on one side of the stalk. Lindley was not aware of its existence in these Provinces, and only quotes it as found in the straits of Malacca and the neighbouring islands. He also says, that it flowers in June and July; but on Tenasserim Coast, March and April are the months in which it is in full bloom.—*Mason.*

(3152) DENDROBIUM TERETIFOLIUM. TAPER-LEAVED DENDROBIUM. An orchid with a filiform tapering leaf is frequent in the suburbs of Maulmain, and though I have never met it in blossom, an English botanist says it is the taper-leaved dendrobium, which Lindley knew only as a New Holland plant.—*Mason.*

(3153) DENDROPHIS (Fitzinger), a genus of Serpents placed by Cuvier under the great genus *Coluber*, and stated by him to be the *Ahaetulla* of Gray. The species of this genus have, like the *Dipsas* of Laurenti, a line of wider scales along the back, and narrower scales along the flanks, but their head is not larger than their body, which is very slender and elongated. Their muzzle is not elongated, and they are not venomous. They inhabit India and Africa.—*Eng. Cyc.*

(3154) DEODAR. CEDRUS DEODAR. The Deodar Cedar or Indian Cedar. Cedar is a name given to several distinct kinds of forest trees. The timber is resinous, has a fragrant odour, a rich yellowish-brown colour, and a bitter taste, owing to which it is not subject to worms—a circumstance which accounts for its great durability. The cedar of Lebanon so famous in Scripture, was in ancient times much employed in the construction of temples, and other religious buildings; in the formation of statues of the heathen deities, &c.—*Faulkner.* The cedar of Lebanon is usually called Pinus Cedrus, but sometimes Cedrus Libanus. The lofty Deodara, a native of the Himalayas, with fragrant and almost imperishable wood, and often called the Indian cedar, is sometimes referred to the genus Pinus, and sometimes to that of Cedrus or Larix, with the specific name of Deodara. Dr. Hooker is of opinion that the Deodar and the cedar of Lebanon are identical. The wood of several of the Conifera however is called cedar. The wood of Juniperus virginiana is called Red or Pencil Cedar, and that of J. bermudiana is called Bermuda Cedar. That of J. barbadensis, is called Barbadoes Cedar; while the Juniper of the North of Spain, and South of France, and of the Levant, is called J. oxycedrus: the White Cedar of North America, a less valuable wood than the red cedar, is yielded by Cupressus thyoides, and the cedar-wood of Japan, according to Thunberg, is a species of cypress. The name Cedar is thus applied to a number of woods in our different colonies, which are in no way related to the Conifera: thus the cedar of Guiana is the wood of Icica altissima. The white wood or white cedar of Jamaica is Bignonia leucoxylon, and the bastard cedar of India is Guazuma ulmifolia. In New South Wales again the term white cedar is applied to Melia Azaderach, and red cedar to that of Flindersia australis, as well as to the wood of the Toon tree, or Cedrela Toona.—*Holtz.* In China, a kind of cedar, probably a cypress, called nan mah, or southern wood, which resists time and insects, is considered peculiarly valuable and especially reserved for imperial use and buildings.—*Williams' Middle Kingdom, page* 275.

(3155) DEODAR OR SHEMANATHU OIL. ERYTHROXYLON ARÆOLATUM. An empyreumatic medicinal oil.—*M. E. J. R.*

(3156) DESMANTHUS NATANS.

Soonday keeray, TAM.

The floating sensitive plant is generally found floating in tanks; the leaflets are used by the natives, though not generally.—*Jaffrey.*

(3157) DESMODIUM. Of this genus of plants, Dr. Wight in Icones gives figures of Desmodium cephalotes, 373; collinum, 272; congestum, 209; diffusum, 298, 409; Gangeticum, 271; gyrans, 294; latifolium, 270; patens, 407; polycarpum, 406; quinqueangulatum, 293; recurvatum, 374; rufescens, 984; strangulatum, 985; triflorum, 291; and β 292.

(3158) DESMODIUM GYRANS. Flowers pale yellow tinged with blue, the lateral leaflets have the power of singular motions.—*Riddell.*

(3159) DESMODIUM LATIFOLIUM. A shrubby plant, bearing handsome purple flowers.—*Riddell.*

(3160) DESMODIUM RECURVATUM.—JUNGLY GANGA. Flowers in the rains, color purple and white.—*Riddell.*

(3161) DESMODIUM TRIQUETRUM. The root of this species of desmodium is valued for its medicinal properties.—*Mason.*

(3162) DEUTZIA, a genus of plants belonging to the natural order *Philadelphaceæ*, inhabit-

ing to the North of India, China, and Japan. The tube of the calyx is campanulate, tomentose, the limb 5 or 6-cleft. The petals 5 or 6, and oblong. The leaves are opposite, petiolate, ovate, acuminated, serrated, wrinkled, and veined. *Deutzia scabra* has its leaves covered with stellate siliceous hairs, which makes them very rough, and renders them of use to cabinet-makers as polishing agents. The siliceous bodies are beautiful objects viewed by reflected light under the miscroscope.—*Eng. Cyc. p.* 320.

(3163) DHAK, or PULAS FIBRE, is obtained from the *Butea frondosa*, also *B. superba* (*Leguminosæ*). One of the most generally diffused plants in Northern India, is the *Dhak* or *Pulas*, as it may be found near many villages, forming their tracts of apparently useless because jungle-like land, but which, in fact, is a place of pasturage for their cattle. The Dhak, which is the most usual shrub thereon, yields firewood, and its bark and roots a fibrous matter, which is used as cordage, or beaten to a kind of oakum and used for caulking boats. Though such fibre is unimportant as an object of commerce, it is of great use to the natives themselves, for agricultural and domestic purposes, as it is possessed of a good deal of strength. Some Pulas fibre was sent to the Exhibition of 1851, from Beerbhoom. A ruby-coloured gum, which has been called *Butea kino*, exudes from incisions into the bark, which, though it abounds in astringent matter, Mr. Teil, of Calcutta, has found difficult to apply to the tanning of leather, but its colouring matter is powerful and permanent. In the jungles, where the Dhak is allowed to grow into a small tree, it is highly ornamental from the splendour of its inflorescence, and is further useful from its large flowers, called *teesoo* and *keesoo*, yielding a beautiful dye, which is likely to come into extensive use. This plant is further interesting, as that from which the name of the Pelasgi has been supposed to be derived by Mr. Peacock, in his 'Greece in India.'—*Royle, Fib. Pl. p.* 297.

(3164) DHAURA KA PHOOL, Grislea tomentosa. These scarlet flowers generally come to Ajmere, from Kotah and Harowtie: are considered stimulating and given to women in labour: are also used in dyeing. One seer costs four annas. The gum of this tree, called *dhaura* or *dhau ka gond*, is brought from Mewar and Harowtee, and is abundant, white in colour, like the katira and tragacanth gums, swells in water: in dying cloth it is applied to those parts that the dye is not wished to touch; it is eaten in "luddoo"; one maund costs ten rupees.—*Gen. Med. Top. p.* 133.

(3165) DHOBIES EARTH; CARBONATE OF SODA. Washermans or Dhobies Earth. Saji mati is a mineral which exists in immense quantities in many parts of India, in Bengal, especially, in the districts of Monghyr, Purnea, and Cawnpore. It contains from 40 to 50 per 100 of carbonate of soda, traces of sulphate of soda, organic matter, clay, sand, and oxide of iron. The salt can be extracted by washing the mineral without incineration, but the organic matter is dissolved at the same time, and gives a deep brown solution from which pure crystals cannot be obtained. The firing destroys the substance, and then the solution is colorless. But care must be taken not to push the heat beyond low redness, for the alkali at a higher temperature combines with the sand and clay, and the whole runs into green glass, insoluble in water. In Europe this salt is prepared either by burning sea weeds and lixiviating the ashes, the product being termed kelp and barilla, or by decomposing common salt by sulphuric acid and then roasting the resulting sulphate with chalk, saw dust, and fragments of iron. The mass when washed gives the carbonate of soda.—*Beng. Phar. page* 360. Southern India is particularly rich in alkaline and earthy minerals, the origin of which seems to be the decaying granites of the country. The most common form of Alkali, is the Dhobee's Earth, a whitish grey sandy efflorescence which often covers miles of country where decayed white granite forms the surface soil; the earth contains from 13 to 25 per cent of crude carbonate of soda and begins to accumulate in the dry weather, immediately after the rains. It can be scraped off the surface to the depth of two or three inches, and by repeated boiling and the addition of a little quick lime, the alkali is obtained of considerable strength; with a little care very clean Carbonate of Soda can be obtained, fit for the manufacture of toilet soap, white glass and glazes for pottery.—Bauloo Moodelly, who has frequently furnished the prepared earth in large quantities for manufacturing purposes. The Nellore, Cuddapah, Masulipatam and Chingleput districts yield this earth in great quantities, and repeated attempts have been made to prepare from it Barilla for exportation and very fair specimens have been exported at different times, but the moderate price of the Carbonate of Soda of England prepared from Sea salt will always prevent this from being a remunerative article of export.—*M. E. of* 1857. The richest in alkali is from the territories of the Nizam, a report of its chemical examination by Mr. R. Reynolds is contained in the Pharmaceutical Journal 1853, Vol. xii. p. 517, shewing the quantity of anhydrous sesquicarbonate to be 67 per cent.—*M. E. of* 1855.

(3166) DHUNCHEE, *Sesbania aculeata* (formerly *Æschynomene cannabina*, Roxb., 'Fl. Ind.,' iii, p. 335, and *Æ. spinulosa*, do., p. 333; *Leguminosæ*). The natives of Bengal familiarly employ and highly esteem a fibre which is known to them by the name of *Dhunchee*, *Dhuncha*, and *Dhunsha*. It is produced by a plant which

Dr. Roxburgh thought was the same as the *Æschynomene cannabina* of Konig. This was described by Retz, and stated to be a native of the Malabar coast, and that its stems yielded a strong and useful fibre, as a substitute for Hemp. Messrs. Wight and Arnott, in their 'Flora of the Indian Peninsula,' consider it to be identical with *Sesbania aculeata-chinensis*, which they have from China. Dr. Roxburgh states that he had not found this plant in a wild state, but that, in various parts of Bengal, it was cultivated for the fibres of its bark, which form a coarse substitute for Hemp. Messrs. Wight and Arnott (l. c.) unite the plant described by Dr. Roxburgh with one which is very common in all parts of India in the rainy season, the *Sesbania aculeata* of Persoon, and which is called Juyunti in Bengal, and *dhundain* in North-West India. It springs up in rice-fields, and other wet cultivation, during the rainy season. These two varieties are thus described by Messrs. Wight and Arnott, under the name of—*Sesbania aculeata*, herbaceous, annual, erect, sparingly branched, glabrous; stem and petioles usually sprinkled with minute cartilaginous points; leaves eight to ten times longer than broad; leaflets twenty to forty pairs, linear, obtuse, mucronate; racemes axillary, peduncled, erect, lax, often about [illegible] the length of the leaves; few-flowered; flowers pretty large (more than half an inch long), on slender pedicels; corolla about four times the length of the calyx; legumes erect, nearly terete, sharp-pointed. Dr. Roxburgh gives the following general directions for its culture. The soil is generally low and wet, and not requiring much preparation, as the plant is hardy, growing from six to ten feet, and rapid in growth. This renders it advantageous to cultivate, especially as it is considered a meliorating crop. The time of sowing is when the soil has been moistened by the first showers of April or May. About thirty pounds of seed are allowed to the acre, and less weeding is required than for *Jute*. The crop is ready to cut in September and October, though the fibre does not differ, if left standing till the seed is ripe, in November. The process of steeping and cleaning the fibre is similar to that required for *Sunn*, that is, *Crotalaria juncea*. The general produce of an acre is from one hundred to one thousand of ill-cleaned fibre, the current price somewhat less than that of *Paut*, viz., *Corchorus olitorius* and *capsularis*. The expense of cultivation, including land rent, is about nine rupees. This plant, generally cultivated about Calcutta during the rains, grows to the height of from six to ten feet, the fibres are long (six to seven feet), but coarser and more harsh than those of Hemp, unless cut at a very early period. From its great strength it is well calculated for the manufacture of cordage and cables. In Bengal, the fishermen make drag-ropes to their nets of this substance, on account of its strength, and durability in water. Indeed, by the Bengalese it is considered more durable in water than either *Sunn* or *Paut*. It has been observed to Dr. Royle by one gentleman well acquainted with this fibre in India, that he was at a loss to know why the Dunchee remained so much neglected in this country, as it is really a very excellent fibre for common cord and twine purposes, and certainly very much superior in strength and durability to Jute. It is also a much hardier plant than Jute; the latter, indeed being rather an uncertain crop, for the production of the fine, long, silky fibre, so much called for in England. Another gentleman observed, that though rather wiry it was strong, and chiefly remarkable for its contraction when wetted, so much so, that it would even carry away the mainmast of a ship by mere contraction. Mr. Deneef, the Belgian farmer, employed in India, presented samples of the Bengal Hemp, called *Dhuncha*, to the Agri-Horticultural Society, in November, 1840, and stated that they had been dressed after the Belgian mode. A begah, he says, will yield 173lb. of cleaned fibre, and 92lb. of seed. A woman can dress about 4lb. a day. In April, 1851, Captain Thompson presented a dressed sample of the fibre of the *Dhuncha* of Bengal, and a piece of rope made of it. This rope, he stated, had been used in various ways for nearly two years, and from various reports upon it, he thought it likely to come into extensive use. Specimens of the fibre and rope were also sent to the Exhibition of 1851, and we have already given the result of the trial made with this rope in the Arsenal of Fort William, whence it appears that a three and a half inch rope of Dhunchee broke with not less than 75 cwt., though the Government Proof, required for such rope, was only 49 cwt. The price of the Dhunchee, in the interior, has long been about R. 1 8 per maund. The following are reports upon this fibre: "The Dhunchee is very suitable for ropes, and if it will take in tar, is of considerable value. It would probably fetch from £30 to £35 a ton, and after being introduced and known, perhaps £5 more." It was also valued by others at £35 in 1853. These fibres, in fact all the fibres from the East, would be much more valuable if properly scutched: and if scutching mills were sent out, these fibres could be brought in a greatly improved state to market. —*Royle. Fib. Pl. page* 293.

(3167) DIACOPE, a genus of Fishes belonging to the section *Acanthopterygii* and family *Percidæ*, and belonging to that section of the family in which the species have less than seven branchiostegous rays, and an interrupted lateral line. This genus is allied to *Servanus*, but may be distinguished by there being a notch or emargination in the lower part of the preoperculum, into which is fitted a projecting tubercle.

Many large and beautiful species of this genus inhabit the Indian seas. *Diacope octolineata*, a very beautiful species, caught off the coast of the Mauritius, is of a brilliant reddish-yellow colour, shaded into white on the belly, and is adorned with four longitudinal blue stripes on each side of the body; these stripes are margined with black. It is about 10 inches in length. Some of the species are known to have attained the length of 3 feet and upwards.—*Eng. Cyc. p.* 323.

(3168) DIACAENA TERMINALIS. Some twenty varieties of this the Ti-plant are cultivated in the Polynesian islands. There is, however, but one which is considered farinaceous and edible. In Java the root is considered a valuable medicine in dysentery.—*Simmonds' Commer. Product, p.* 355.

(3169) DIAMOND.

Viram also Vachira Kulloo, Tam.
Mass, Pers.
Intan, Malay.
Faulkner, Ainslie.

A crystallised mineral, which, on account of its lustre and hardness, is reckoned the most valuable of all gems. It occurs generally in single or unattached crystals, sometimes with plain, but more frequently with rounded surfaces. The colours are commonly white or gray, sometimes, however, red, brown, yellow, green, blue, and black, but the two last are rare. Lustre splendent, and internally perfect adamantine. Diamonds are chiefly found disseminated in gravel, or embedded in sand-stone in India, Brazil, and the Ural mountains.—*Faulkner.* Carbon, is an elementary substance of first-rate importance in chemistry both organic and inorganic, and also in the Useful Arts. It is very widely diffused throughout the kingdoms of nature, and exists under an immense variety of forms. The purest form of carbon is the *diamond*, which is found in the Ceded Districts, in Golconda, Punna in Bundelcund, in India, in Borneo and also in Brazil. All the largest diamonds were from Golconda, (*Tomlinson, page* 306) but the site is supposed to be now built over and lost. The combustibility of the diamond was ascertained by the Tuscan Philosophers and the Hon. Mr. Boyle, who, by exposing a diamond in the focus of a large lens, consumed and dissipated it. The art of cutting and polishing diamonds is supposed to have originated in Asia at some unknown period. Diamonds are cut into various forms, called the *Brilliant*, the *Rose*, and the *Table*. The first form shows the gem to the best advantage and is always set with the table upwards. In the rose the entire surface is covered with equilateral triangles terminating in a sharp point at the summit. This form is used when the spread of surface is too great for its depth, and it could not be cut into the brilliant form without great loss. The table is applied to such diamonds as may be regarded as plates, laminæ, or slabs, of small depth compared to their superficial extent. The brilliant and the rose lose in cutting and polishing somewhat less than half the weight.

The *Pitt* or *Regent diamond* has been valued at 400,000*l.*

The *Pigot diamond*, weighs 49 carats, and is valued at 40,000*l.*

The *Austrian diamond*, weighs above 139½ carats.

The grand *Russian diamond*, is said to have been the eye of an Indian idol. It fell into the hands of a merchant, who sold it to Prince Orloff for Catherine, Empress of Russia, for 90,000*l.* in cash, an annuity of 4,000*l.*, and a patent of nobility. It weighs scarcely 200 carats.

The *Koh-i-noor*, or "*Mountain of Light*," the largest known diamond in the world, excepting the Brazilian stone among the crown jewels of Portugal, has lately been added to the trophies of the British sovereign. It was in the year 1550 before the Mogul dynasty had been established by the prowess of the great Akbar, that this marvellous stone was discovered in the mines of Golconda. It passed in the train of conquest and as the emblem of dominion, but always carrying misfortune in its train, from Golconda to Delhi, from Delhi to Mushed, from Mushed to Cabul, from Cabul to Lahore and from Lahore to London. When first given to Shah Jehaun, it was still uncut, weighing, it is said, in the rough state, nearly 800 carats, which were reduced by the unskilfulness of the artist to 279, its present weight. It was cut by Hortensio Borgio, a Venetian, who, instead of receiving any remuneration for his labour, was fined 10,000 rupees by the enraged Mogul. Small diamonds and fragments made up in small sealed bags are sold in the East by the diamond merchants. According to Jaffries, the value of diamonds is in the duplicate ratio of their weights. Thus, if an uncut diamond of one carat be worth 2*l.*, that of one cut and polished would be valued at 8*l.* sterling in the brilliant. A carat weighs four nominal grains, or 3·166 grains troy. At this rate a cut diamond of two carats would be $2\times8\times2=32l.$; one of three, $3\times8\times3=72l.$; one of four, $4\times8\times4=128l.$; and one of five, $5\times8\times5=200l.$ The rose diamond is of inferior value but has been rated at 4*l.* the carat when polished. For the purpose of estimating diamonds of inconsiderable size, the jeweller employs a gauge, in the handle of which are embedded small crystals of various relative sizes, from $\frac{1}{16}$th to $\frac{1}{4}$th of a carat, and a comparison is therewith made when there are numbers of various minute sizes. The rough diamond is called *bort*, and *points* are those small fragments

which are set in glaziers' cutting diamonds. The chief application of the diamond is for ornamental jewellery, but there are other interesting applications of this gem in the useful arts. It has been employed in common with the sapphire and ruby in some descriptions of wiredrawing.—*Tomlinson, p.* 309. According to the English Cyclopedia, for ornamental purposes diamonds are cut into two shapes: namely, Rose-Diamonds and Brilliants, the former being, for the most part, made out of the octahedral crystals, and the latter from those with curvilinear faces. The weight and consequently the value of diamonds are estimated in carats, each of which is equal to 3·166 grains. In the formation of either a brilliant or a rose-diamond so much is cut away that the weight of the polished gem is not more than half that of the rough crystal out of which it was formed. Diamonds occur in India in the district between Golconda and Masulipatam, near Punna, in Bundelcund, also on the Mahanuddy, and in Ellore. They have been obtained in Borneo, on the west side of the Ratoos Mountain, with gold and platina. The Brazillian mines were first discovered in 1728, in the district of Serra de Frio, to the north of Rio de Janeiro. The largest diamonds are procured on the river Jequitinhonha, which is called the Diamond River, also Rio Pardo. In the Ural Mountains diamonds were detected in 1829, by Humboldt and Rose, in their journey into Siberia. In the United States the diamond has been met with in Rutherford country, North Carolina, and Hale country, Georgia. They have been found on the river Ginul, in the province of Constantine, in Africa. They have also been discovered in Australia, and of such size as to render it probable they may add yet more to the mineral treasures of that country. The rocks in which the diamond occurs in Brazil are either a ferruginous quartzose conglomerate, or a laminated granular quartz called *Itacolumite*. The latter rock occurs in the Urals, and Diamonds have been found in it; and it is also abundant in Georgia and North Carolina. In India the rock is a quartzose conglomerate. In most instances diamonds are obtained from alluvial washings. In Brazil the sands and pebbles of the diamond streams are collected and washed under a shed by a stream of water passing through a succession of boxes. A negro washer is stationed at each box. When a diamond is found weighing 17½ carats the negro is entitled to his liberty. "The largest diamond of which we have any knowledge is mentioned by Tavernier as in the possession of the Great Mogul. It weighed originally 900 carats, or 279·63 grains, but was reduced by cutting to 861 grains. It has the form and size of half a hen's egg. It was found in 1560, in the mine of Colone. The diamond which formed the eye of a Brahminical idol, and

was purchased by the empress Catharine II. of Russia from a French grenadier, who had stolen it, weighs 193 carats, and is as large as a pigeon's egg. The Pitt, or Regent Diamond, is of less size, weighing but 236·5 carats, or 419½ grains; but on account of its unblemished transparency and colour it is considered the most splendid of Indian diamonds. It was sold to the Duke of Orleans by Mr. Pitt, an English gentleman, who was governor of Bencoolen, in Sumatra, for 130,000*l*. It is cut to the form of a brilliant, and is estimated at 125,000*l*. Napoleon placed it in the hilt of his sword of state. The Raja of Mattan has in his possession a diamond from Borneo weighing 367 carats." (Dana.) The great diamond mentioned in the above extract as in the possession of the Great Mogul appears to be the identical diamond which, under the name of Koh-i-Noor, excited so much attention at the Great Exhibition in 1851. Some doubt is thrown on Tavernier's statement of its being cut. This precious gem has seen a variety of fortunes. Its early history is mythical. From the Great Mogul it passed into the possession of the reigning family of Cabul. When Shah Suja was driven from Cabul he became the nominal guest and actual prisoner of Runjeet Sing, who spared no means to obtain possession of the precious gem. In this he succeeded in 1813. After the death of Runjeet the diamond was preserved for a while by his successors. It was occasionally worn by Khurruk Sing and Shere Sing. After the murder of the latter it remained in the Lahore treasury until the supercession of Dhuleep Sing and the annexation of the Punjab by the British government, when the civil authorities took possession of the Lahore treasury, under the stipulation previously made that all the property of the state should be confiscated to the East India Company, in part payment of the debt due by the Lahore government and of the expenses of the war. It was at the same time stipulated that the Koh-i-Noor should be surrendered to the Queen of England. It arrived in England on the 30th June, 1850, and on the 3rd of July was presented to her Majesty. Since its public exhibition in 1851 it has been submitted to the process of cutting, which has much enhanced its beauty and value. The diamond is cut by taking advantage of its cleavage, and also by abrasion with its own powder, and by friction with another diamond. It is a process of great labour, and many hours are spent in producing a single facet. Diamonds were first cut in Europe in 1456 by Louis Berquen, a citizen of Bruges. The diamond is used for cutting glass. It is also employed for the lenses of microscopes. It has but little chromatic aberration, but the frequent irregularity of its structure is a drawback to its employment for this purpose. (Dana, *Manual of Mineralogy; Catalogue of Great Exhibition of* 1851, Class xxiii.)—*Eng. Cyc.* 328.

The Diamond, in Malay and Javanese is called intan, and sometimes kumala. The Diamond has been found in no part of the Asiatic Archipelago except Borneo, and even in that island only in a comparatively small part of it, a portion of its western coast. The principal diamond mines are in the district of Landak, in the territory of Pontiyanak, in the longitude of 109° east, about forty miles north of the equator, and they occur from thence as far as Banjarmasin, in south latitude between three and four degrees and longitude between 114° and 115° east. The mines are worked by the wild Dayaks and the Malays, but with far superior skill by the Chinese. The gems are found in a yellow-coloured rubble or gravel, which occurs at various depths, the greatest to which a shaft has been known to be sunk being between fifty and sixty feet. When a shaft of such a depth is sunk, six different alluvial strata occur before reaching the diamond-yielding one, which the Malays call the Areng. These strata are, a black mould, a yellow sandy clay, a red clay, a blue clay, a blue clay intermixed with gravel, called by the Malays "ampir" or "near at hand," and lastly, a stiff yellow clay, in which the diamonds are imbedded. The largest diamond found in the Bornean mines of late years was only of thirty-two carats. The prince of Matan, however, has long had in his possession, a rough diamond of 367 carats, but its genuineness has been suspected. At present the Dutch Government are the owners of the diamond mines, and make advances to the miners, who are bound to deliver all stones at twenty per cent below their market value, which is equivalent to a seignorage of twenty-five per cent. Under this management there were delivered in 1824 no more than 900 carats, and the quantity in the two subsequent years was still less.—*Crawfurd Dic. p.* 120. According to Ainslie the diamonds which are offered for sale in India were generally brought from Visiapour, Gana Purtual (Golconda), Bundlecund, the Island of Borneo, or Sumbhulpoor in Orissa and were reckoned superior in transparency and purity to those of Brazil. What is sometimes called the Maturese Diamond of Ceylon, or yellow Tourmalin (Kanefie Turmali), Thunberg tells us is no other than a Topaz of a greenish yellow colour, no Diamonds are found in the Dominions.—*Ains. Mat. Med. page* 165. As to the diamonds of Musulipatam, the mines from which these stones were formerly dug, are reserved by the Hyderabad State, and still belong to the Nizam, and small patches coloured yellow on the map, mark the Villages where the mines are situated. They have not been touched for many years, they might now, even, be as profitably worked, as they once were, not much more than a few feet from the surface, but they are so choked that it would be impossible to do any thing in a limited time, the diamond is not found in Burmah, yet it forms one of the nine gems, which, worn together in a ring, are supposed to protect the wearer from evil. They are the diamond, emerald, coral, sapphire, topaz, pyrope, cat's-eye, pearl, ruby.—*Mason.*

(3170) DIANTHUS, a beautiful genus of Silenaceous Dicotyledonous Plants, with a calyx closely covered at the base by two, three, or four opposite pairs of decussating rigid sharp-pointed bracts. The petals are always more or less lacerated at the end, and in some species are divided into fine capillary segments. There are 10 stamens, 2 styles, and the capsule is 1-celled, with numerous black seeds containing a straight embryo. In all cases the leaves are long, narrow, 1-ribbed, sharp-pointed, and destitute of all lateral reticulated veining. De Candolle enumerates 113 species, of which some must undoubtedly be reduced to simple varieties. They are found in all the temperate parts of Europe and Asia, from Ireland to the eastern coast of China and Japan; two have been met with in the United States of America, and four at the Cape of Good Hope. Most of them are perennial herbaceous plants with permanent leaves and stems, and hence they ought perhaps to be considered undershrubs; a few become woody and form genuine bushes.—*Eng. Cyc. page* 235. All these plants are herbaceous, with opposite leaves and terminal flowers. Of upwards of a hundred species scarcely any possess the least activity. The *Dianthus caryophyllus*, or clove flower, is fragrant and aromatic; and the petals being of a lovely pink tint are used in some parts of Europe for preparing a syrup and conserve. The Dianthus chinensis is of analogous qualities, and is cultivated in Indian gardens under the name of *Kurunphul.*—*O'Shaughnessy.*

(3171) DIANTHUS CARYOPHYLLUS.—The Clove Pink or Carnation has long been a favorite flower and is now almost acclimated. It seldom ripens its seed, and two varieties are only to be met with in the Deccan. The dark crimson is not so full a flower as the variegated crimson and white; they both possess equal perfume and fragrance, but the latter, when carefully grown, is certainly the most beautiful. A full grown carnation should neither have its petals too crowded nor too thin, but regularly disposed, so that all its beauties may be observed at once. The stem or foot stalk seldom exceeds eighteen inches, and this should be carefully supported. It is propagated by layers and pipings; also by seed when procurable. The plant must always be sheltered from heavy rains, and also from the hot winds; yet kept in an airy situation. If placed under cover for any length of time, they run up to thin stalks, seldom throwing out blossoms. The time for taking cuttings is when the plant is in blossom; and this may be done either at the commencement of the rains, or in the cold weather. When the plants appear to be about

to blossom, all the buds save a couple should be carefully removed, as well as any small shoots on the foot stalk between the leaves. When layers are required, they must be removed from the stem with a knife or scissors, and should not be longer than two or three joints. Cut off all the lower superfluous leaves smooth, then throw the layers into water for a couple of hours. Plant them in baskets, at about six inches apart, which have been filled with old rich vegetable loam: water so as to settle the earth round the stems, and place in a shady spot, not under trees, if in the rainy season. In about six weeks they will have struck, and may be removed into pots. Do this carefully, not disturbing the earth round the young roots, which are very tender, and replace in the shade again until sufficiently strong to bear exposure to the sun. The variegated have only two colours, and when stripped are called Flakes, but if spotted, Picotees. Ants (black, red and white) are very destructive to the roots. An old plant of Flakes or Picotees, will occasionally lose both stripes and spots during the hot season, and become quite white when in flower, but resume during the rains their original colours of deep red and white. The colour thus changing may be justly attributed to the dry hot weather, as it has been remarked in England, that sometimes fine double running flowers have returned to their whole or original colour during very dry or warm summers.—*Riddell.*

(3172) DIANTHUS CHINENSIS. Common in all gardens—of various colours, and some mixed—they flower all the year round, and give seed immediately as it fades, and which will spring up again if sown. The double flowered varieties are much esteemed: the colours are white, red, crimson, red and white.—*Riddell.*

(3173) DIAPER.

Drel, Dut.	Tela tessuta a opere, It.
Linge ouvre, Fr.	Salfetotsschnoe, Rus.
Drell, Ger.	Manteles alemaniscas, Sp.

A sort of fine flowered linen, commonly used for table cloths, napkins, and other domestic purposes. It is manufactured in the north of Ireland, Germany, and Scotland. Diapers are also made of cotton, in imitation of the linen goods bearing the same name. Shot Diaper from Masulipatam (CXLII-455) so made that it was difficult to ascertain whether it was not shot with silk. After a most rigid examination it was ascertained to be a Cotton Fabric, excellent in quality and color, and being the only piece in the Exhibition the Jury considered it entitled to a 2d Class Medal.

(3174) DIDYMOCARPUS, a genus of plants of which Dr. Wight gives 10 species, Didymocarpus Humboldtiana, 1851; lyrata, 1350; ovalifolia, 1351; Rottleriana, 1348; and tomentosa, 1349.

(3175) DIDYMOCARPUS AROMATICUS, is stated by Dr. Wallich to be used as a perfume and aromatic drug, called by the natives *Kumkuma* and *Ranigovindi* (*Royle*, p. 294.)—*O'Shaughnessy, page* 448.

(3176) DIDISCUS CÆRULEUS. Umbelliferæ. These plants are from Australia, and are grown from seed in a light loamy soil, and the plants either reared in pots or in flower-beds.—*Riddell.*

(3177) DIKAMALLEE, is the gum of Gardenia lucida; it exudes in amber colored transparent drops, at the ends of young shoots, and from thence it is collected. It is most useful in preventing vermin feeding in wounds. At the Madras Exhibition of 1855, this product by the Gardenia lucida of Roxburgh, was shown from Canara, Mysore and Guntoor—this fragrant resin is useful in Hospitals, keeping away flies from sores, on account of its strong aroma, and is an article in the materia of the village farrier. It deserves more attention.—*M. E. J. R.* Dikamali, from Gardenia gummifera, is stated by Dr. Gibson to be produced within the Bombay Presidency, its effects in preventing the access of flies to festering wounds and running sores, is remarkable.—*Spry's Suggest, page* 67.

(3178) DICE,

Taarlingen, Dut.	Dadi, It.
Des (a jouer), Fr.	Kosti, Rus,
Wurfel, Ger.	Dados, Sp.

Are cubical pieces of ivory, bone, or ebony, marked with dots on each of their sides from 1 to 6, according to the number of the face; and used for playing games of chance.—*Faulkner.*

(8179) DICHROSTACHYS CINEREA. *Mimoseæ*, Roxb. c. 174.

Vadatala marum, Tam.

A small tree or rather large shrub, wood very hard and strong, but too small for any except common purposes.

(3180) DILL SEED,

Buzralshibet, Shubil, Arab.	Anethi Semina, Lat.
Satta-copa, Cyng.	Misreya, Sitasiva, Seleya, Sans.
Soie, Duk.	Saddacuppei, Tam.
Sowa, Guz. & Hind.	Suddapu, Tel.
Mungsi, Jav.	

Are flattened elliptical seeds with brown and slightly convex backs, and pale membranous margin. Both the fruit and the plant are much used in the East as condiments and articles of diet. The carpels have a bitter aromatic taste, making them useful as carminatives. The plant is a native of the South of Europe, and some parts of India; the seeds are procurable in all Indian bazars.—*Faulkner.* The Indian species is Anethum sowa. *Dill* leaves are used to flavour pickles, the seed as a carminative, and is supposed to be used in the manufacture of gin: raised from seed.—*Jaffrey.*

(3181) DILLENIACEÆ, a natural order of Plants belonging to Polypetalous Albuminous Exogens, and related on the one hand to *Magnoliaceæ*, on the other to *Ranunculaceæ* and to *Anonaceæ*. They are briefly characterised by having 5 sepals in a broken whorl; 5 petals; an indefinite number of stamens; a definite number of ovaries, which are either quite distinct or more or less consolidated; berried or capsular and 2-valved fruits; seeds surrounded by a pulpy aril; and, finally, a minute embryo lying in solid flesh albumen. Differentially considered, Dilleniaceous Plants are distinguished from *Anonaceæ* by their flowers being arranged upon a quinary, not ternary, type, by their albumen being solid, and not ruminated, and by their want of aromatic properties; from *Magnoliaceæ* by their want of stipules, and the presence of a pulpy aril round the seeds. The plants of this order are chiefly Asiatic trees or shrubs, and usually yellow-flowered. A few occur in America. The trees are found in the woods of tropical India; the bushes inhabit Australia, especially in the more temperate parts, and in China; the woods of Brazil contain several kinds, usually climbers or having a trailing habit. They appear to possess astringent properties, but nothing further of importance. The species in cultivation in England are almost all Australasian, and have something the appearance of yellow-flowered *Cistuses*. Among these occur species of the curious genus *Pleurandra*, in which the stamens are developed on one side only of the flower, all those on the opposite side being abortive. There are few analogies to this in the vegetable kingdom. *Hibbertia volubilis* is a showy twiner, but its flowers are intolerably offensive in their smell. The Indian species are in almost all cases plants of great beauty. They are remarkable both for the grandeur of their foliage and the magnificence of their flowers. Several species of *Dilleniaceæ* are large trees, and afford valuable timber.—*Eng. Cyc. page* 342.

(3182) DILLENIA, a genus of Plants, the type of the natural order *Dilleniaceæ*. The young calyces of *D. scabrella* and *D. speciosa* have a pleasant taste and are used in curries by the inhabitants of Chittagong and Bengal. Several species of *Dillenia* are large trees, and afford hard, durable and valuable timber.—*Eng. Cyc. p.* 342.

(3183) DILLENIA. The flowers of one of this genus, as it occurs in the Terai, are as large as two fists.—*Hooker, Him. Jour. page* 395. Dr. Wight gives figures of Dillenia bracteata, 358; *retusa*, 358; speciosa, 823.

(3184) DILLENIA, Water Dillenia. A species of dillenia always found on the borders of streams, hence called water dillenia by the Arabs, produces a large fruit, which is brought to bazar green, and considered a favorite vegetable with the natives.—*Mason.*

(3185) DILLENIA. 1. *Dillenia augusta*, 2. *D. scabra* and 3. *D. speciosa*. The Burmese names of which are 1. Zinbyewn, 2. Byew, 3. Thabyew. The two first are plentiful in the forests of the Pegu district, but become scarce to the north of it, and the third species is scarce even there. They all three afford large and good timber for house-building. Light brown wood.—*McClelland.*

(3186) DILLENIA ORNATA. Ornamental Dillenia. When a stranger debarks at Maulmain in February, his attention is arrested by a tree without a leaf, but covered with large gaudy yellow flowers: it is the ornamental dillenia. Several other species of the genus are indigenous in the Provinces.—*Mason.*

(3187) DILLENIA PENTAGYNA. Dilleniaceæ.

Rowadan, Tel.

This is a large timber tree a native of the Northern Circars, and flowers in March and April. *Roxb.—Rohde M.S.S.* The similarity of native names between this and Calophyllum inophyllum led Dr. Wight to suspect some mistake. The wood of Dillenia pentagyna is said to be exceedingly strong and very durable, even when buried under ground. A stately forest tree, common on the face of the W. Ghauts. Dr. Wight is satisfied that this is the tree which furnishes the Poon spars. D. pentagynia is a tall and Calophyllum inophyllum a short stunted tree.—*Wight.*

(3188) DILLENIA SPECIOSA. Dilleniaceæ.

Girnar, Hind.	Chalta, Beng.
Moota Kurmul, Dur.	Uvachettoo, Tel.

A large tree; flowers white and yellow, nine inches in diameter; fruit size of a cocoanut.—*Riddell.* It is a most beautiful tree when in flower. It is a native of vallies far up among the Circar mountains: it is also found cultivated in some gardens on account of its elegant appearance. It flowers during the hot season and beginning of the rains, the seed ripens in February. The fleshy leaflets of the calyx, when the fruit is full-grown have an agreeably acid taste, and are much used by the Natives, where the tree grows, in their curries. They make a tolerably pleasant jelly, the wood is both hard and tough, and is used to make gun stocks. Roxb.—*Ovai-kai*, Tam. is the fruit of this large and handsome tree, and is used by the lower class of natives in their curries, having an agreeable acid flavour; and also in chatnies.—*Jaffrey.* It is abundant in the Kotah jungles, the very large bright yellow blossoms are most magnificent. This tree would be exceedingly ornamental in compounds and would thrive well, being very hardy.—*Gen. Med. Top. page* 199.

(3189) DIMITY.

Basin, Fr.	Doblet, It.	Dimite, Sp.

A cotton stuff, similar in fabric to fustian,

from which it differs chiefly in having ornaments woven on it, and in not being dyed. Its colour should be delicately white.—*Faulk.* According to Tomlinson, dimity is a stout cotton cloth ornamented either with raised stripes or figures, and employed white for bed and bed-room furniture. —*Tomlinson, page* 490.

(3190) DINDUGA TREE. ANDERSONIA. Roxb.

Bayla Nava marum, TAM. | Dinduga, CAN.

This large and valuable tree grows in Wynaad. —*Ains. Mat. Med. p.* 213.

(3191) DIOMEDEINÆ, a family of Birds to which the Albatrosses belong. The characters of the genus *Diomedea* are given under ALBATROSS. In that article three species of this genus are referred to. We now give a complete list of the species of this important genus :—

Diomedea exulans.—Linn. This bird is abundant between 30° and 60° S. lat., and equally numerous in all parts of the ocean bounded by those degrees ; its range however extends much farther south, even to within the antarctic circle.

Diomedea melanophrys.—Temm. It is the most abundant species of the southern seas ; equally numerous in every part between the 30th and 60th degrees.

Diomedea cauta.—Gould. This species was procured by Mr. Gould off the south coast of Van Diemen's Land.

Diomedea chlororhynchos.—Lath. It occurs between 30° and 60° S. lat., in both the Atlantic and Pacific Oceans.

Diomedea culminata.—Gould. This bird is rather abundant both in the Pacific and Atlantic Oceans, between 30° and 50° S. lat.

Diomedea fuliginosa.—Gmel. It occurs in all parts of the ocean between 30° and 60° S. lat. : equally common off Van Diemen's Land, Cape Horn, and the Cape of Good Hope.

Diomedea brachyura.—Temm. Found in the North Pacific Ocean.

Diomedea gibbosa.—Gould. An inhabitant of the North Pacific Ocean.

Diomedea olivaceorhyncha.—Gould. China seas (?). Mr. Gray, in his ' Genera of Birds,' also gives *D. spadicea* as a species. He also makes *D. gibbosa* (Gould) synonymous with *D. nigripes*, Audubon, ' Biog.,' vol. v. p. 327, and adopts the latter name as having the priority.—*Eng. Cyc. p.* 353.

(3192) DIOSCOREACEÆ, *Yams*, the Yam Tribe, a natural order of Plants belonging to the class Dictyogens. They are particularly distinguished by the following characters :—Flowers diœcious ; calyx and corolla superior ; stamens 6; ovary 3-celled, with 1 or 2-seed cells; style deeply trifid ; fruit leafy, compressed, occasionally succulent ; embryo small, near the hilum, in a large cavity of cartilaginous albumen. The affinities of this order are with *Smilaceæ* and *Aristolochiaceæ*. It contains 6 genera and 100 species. All the species are twining shrubs, with alternate or spuriously opposite leaves. They consist, with the exception of *Tamus*, Black Bryony, of tropical plants, or at least of such as require a mild forestless climate. Some of them produce eatable farinaceous tubers, or yams, as the various species of *Dioscorea* and *Testudinaria* ; but there is a dangerous acrid principle prevalent among them, which renders the order upon the whole suspicious. It exists in a perceptible degree in *Tamus*, and is still more manifest in the 3-leaved *Dioscorea.*—*Eng. Cyc. p.* 355.

(3193) DIOSCOREA, a genus of Plants which furnish the tropical esculents called Yams. It is the type of the natural order *Dioscoreaceæ*. The genus consists of perennial fleshy-rooted or tuberous diœcious plants, with annual twining stems, broad alternate leaves having a somewhat netted arrangement of their veins, and loose clusters of small green flowers. The corolla and the calyx taken together consist of 6 small, equal segments, which, in the females, stand upon the top of the ovary. The male flowers have 6 stamens ; the females 3 styles. The seed-vessel is a thin compressed 3-winged capsule, containing one or two membranous seeds. The best account of the species is that of Dr. Roxburgh, who cultivated seventeen sorts in the Botanic Garden, Calcutta ; others are known to botanists, but far from perfectly.—*Eng. Cyc. p.* 355. Wight figures Dioscorea aculeata, 2060 ; alata, 810 ; *amœna*, 811 ; bulbifera, 878 ; dœmona, 811 ; globosa, 812 ; oppositifolia, 813-2060 ; pentaphylla, 814 ; and tomentosa, 815. It is not a little remarkable that while so many species are nutritious in this genus, some should be highly dangerous ; but such is unquestionably the fact. *D. Dæmonum* and *D. triphylla*, both ternate-leaved species, have very nauseous and dangerous tubers. Eatable sorts are numerous. In Otaheite the *D. bulbifera*, which bears small fleshy angular tubers along the stem in the axils of the leaves, is the favorite species.—*Eng. Cyc. page* 355.

(3194) DIOSCOREA. In the Eastern Archipelago the dioscorea yam plant is universally cultivated among all the tribes, and generally most so where rice is least abundant, but it no where forms the chief bread of the people, as rice, maize, or sago do. The batata, indeed, and Crawfurd thinks justly, is preferred to it. The Malay and Javanese name, rubi or uwi, extends not only to the languages of the Malay and Philippine Islands, but to those of the Pacific, and to Madagascar. In the Philippine languages the name is identical with that in Malay ; in the Tonga it is ufi ; in the Tahiti eui ; in the New Zealand the same as in Javanese, namely, uwi ; in the languge of New Ireland u, and in the

Madagascar uwi. With all these varieties of pronunciation there can be no doubt of the virtual identity of the name. It is probable that several species of Dioscorea are natives of the Malayan Archipelago, but that the culture originated with one people, and was directly or indirectly disseminated by them, seems likely from the universality of the name. It may be remarked, that in the language of Madagascar, a wild yam is called uvi-ala, which is, without doubt, the Uwi-alas—the wild or forest yam of the Javanese, with the elision of the final consonant, conformably to the genius of Malagasi pronunciation. The word ubi, besides being applied specifically to the yam, is used as a generic for farinaceous roots. Thus the batata, or Convolvulus batatas, is called by the Malays Uvi-jawa, or the Javanese yam, to distinguish it from the Dioscorea.—*Crawfurd Dict. page* 448.

(3195) DIOSCORIA. ELEPHANT-FOOT YAM. A yam with a tuber about the size and shape of an elephant's foot, is white, and often as light and agreeable as a potatoe. It abounds in Karen gardens but is rarely seen among the Burmese, or in the market.—*Mason.*

(3196) DIOSCOREA ACULEATA. BENDALOO. Lin.

Sirroo vullie Kalung, TAM. | Poodiekelengu, MAL.
Chota Pendaloo, DUK. |

The small yam. This is a very valuable and delicate root, somewhat resembling the sweet potatoe in appearance; tubers of an oval form and very white, generally weighing about two pounds. The taste is more like that of a fine dry yam.—*Ainslie, page* 251. Mr. Jaffrey describes Dioscorea aculeata, as Kantoo Kelangoo, *Tam.*, and the Goa potatoe; but is not aware if this yam be much cultivated in Madras. There are many species of the yam cultivated for various purposes, Dioscorea triphylla is used to render the Cocoanut tree toddy more intoxicating. D. pentaphylla, the flowers are used as greens, and the tubers as an esculent. D. bulbifera for a similar purpose. The genus is very extensive; and some of the species are poisonous.—*Jaffrey.*

(3197) DIOSCOREA ALATA. Lin.

Cachay kalung, TAM.

This root appeared to Dr. Ainslie to be the Katsje Kelenghse of the Hortus Malabaricus, and the plant the Ubi of the Malays and Javanese, who eat the root when dressed. Vide Rumphius, Tom.—*V. p.* 348. *D. alata*, the common West India Yam, is a native of the West Indies, although met with in the East Indies also, but only in a cultivated state. A figure of it is given in Rheede's 'Hortus Malabaricus,' vol. vii. t. 38, under the name of Katsji-kelengu. Its tubers are oblong, brown externally, white internally, and often of great size, weighing sometimes as much as 30lbs.; they perish after the first year, if left in the ground, having first produced the young ones that are to replace them. "Besides the tubers, the proper roots of all these plants are fibrous, springing from and chiefly about the union of the stems with the tubers, and spreading in every direction." The stems are furnished with four crested leafy wings, and spread to a great extent, twining round trees and bushes; they often bear prickles near the ground. The first leaves that appear on the stem are alternate, the succeeding are opposite, seated on long stalks, deeply heart-shaped at the base, sharp-pointed, smooth, with from five to seven ribs. The flowers are small and green, and appear in compound panicles. The remainder of the species are very similar to this in general characters: a few short notes will sufficiently indicate their differences.—*Eng. Cyc.*

(3198) DIOSCOREA ATROPURPUREA. DARK PURPLE YAM. A yam with a dark purple root is one of our best yams, and is extensively cultivated both by Karens and Burmese. —*Mason.* This purple-rooted sort, the *D. atropurpurea*, is cultivated at Malacca, tubers are large and irregular, and grow so near the surface of the ground as to appear in dry weather through the cracks that they make in the soil by raising the earth over them.—*Eng. Cyc.*

(3199) DIOSCOREA BATATAS, the Chinese Yam, was introduced into Europe about the year 1849, having been sent from Shanghai, by M. de Montigy, the French Consul. It is every where cultivated in China and bears the names of *Chow-yu*; *Ton tchow*; *Chan-chow*; *Chan-yo and Chan-yu*, which signifies the "Arum of the Mountain." At Nankin, it is very large and of excellent *flavour*; *that of the* chou district is still better, but for medicinal purposes, the Chinese prefer that of the Hoai-king district, where the Chou-yu root is laxative and sweet. It is particularly worthy of a place in the kitchen garden, as well as in field culture, on account of its perfectly feculent flavour, and the absence of any after-taste of sweetness, acidity, or spiciness, such as is often found in other plants; as also on account of the ease with which it may be cultivated and the facility of preserving it from decay. Agricultural Rep. to Commissioners of Patents to House of Assembly for 1854.

(3200) DIOSCOREA DÆMONA. WILD YAM. There are several indigenous species of yams, which are eaten by the Karens in times of scarcity, though very acrid. One is remarkable for its large ternate leaves, of which the leaflets are sometimes nearly a foot long, and six inches wide.—*Mason.*

(3201) DIOSCOREA FASCICULATA. KAREN POTATOE. This is a small yam not much larger than a kidney potatoe, which it much resembles both in appearance and taste. It is cultivated extensively by the Karens, and being

more like a potatoe than a yam, has acquired the name of the Karen potatoe, and is sometimes called the Tavoy potatoe. It is the best vegetable they have, but unfortunately it can be obtained during a few months only in the year. Mr. Mason is not aware that it is ever found wild on the Tenasserim Coast; and it appears to him to be either identical, with or nearly related to Roxburgh's D. fasciculata.—*Mason.*

(3202) DIOSCOREA GLOBOSA, cultivated in Bengal under the name of Choo-puree-Aloo, is the most esteemed of the Indian Yams. Its flowers are highly fragrant; the tubers are white internally; the leaves arrow-headed.—*Eng. Cyc.* In Tenasserim, though there are several different species and varieties of white yams in cultivation, *Dioscorea globosa*, the large white yam, is the one most in repute; it has arrow-headed cordate leaves. —*Mason.*

(3203) DIOSCOREA PENTAPHYLLA. Lin.

Noorang kalung, Tam.

The root, in some parts of Southern India, is called kaat vulli kalung or Wild Yam. It appears to be the Nooren keelengu of the Hortus Malabaricus and the On do of the Malays. Rumphius tells us that previous to preparation it contains much acrimony, adding, "Creator sapienter hanc impraegnavit radicem hoc succo, ut "ab ipris intacta hominibus cibo inserviret."—*Ainslie*, v. 249.

(3204) DIOSCOREA PURPUREA, called Kal-Guranya-Aloo in Bengal. The tubers are permanently stained purple throughout.

(3205) DIOSCOREA RUBELLA, the Guranya-Aloo, is another Indian sort, with large tubers stained with red immediately below the cuticle; it is much esteemed; its tubers are sometimes three feet long; its flowers are fragrant.

(3206) DIOSCOREA SATIVA. Yam. Lin.

Yamkalum, Tam. | Perinvullie kelengu, Tel.

This most valuable root is too well known to require any description here: it is eaten all over India by both Europeans and Natives and is by some, preferred to the potatoe.—*Ainslie, p.* 251.

(3207) DIOSCOREA PURPUREA.

Poothooschary valle Kelangoo, Tam.

Pondicherry sweet potatoe. A yam not much used in Madras, the roots are boiled and eaten as a potatoe.—*Jaffrey.*

(3208) DIOSPYROS (from δios and πυρὸς, which may be translated 'celestial food'), a genus of Plants belonging to the natural order *benaceæ*. They all form large trees, with alternate thick, often coriaceous leaves. The flowers are usually single and axillary, the male and female flowers separate or united. Calyx and corolla 4-cleft, rarely 5-cleft. Stamina often 16, but varying in different species. Germen superior, often 8-celled; cells 1-seeded; attachment superior. Styles 3 or 4 rarely 5, or 1, and variously divided. Berry from 1-to 12-seeded, often 8-seeded. Embryo inverse, and furnished with albumen. Male flower frequently with twin anthers. The species are found chiefly in the tropical parts both of Asia and America, as in the Malayan Archipelago and Peninsula, and in almost every part of India. One species extends southward to Australia; one, *D. Lotus*, to Switzerland; and *D. Virginiana* into the United States of America. As some are remarkable for the wood which they afford, and others on account of their fruit, it is necessary only to notice a few of each, though the whole require the labours of a monographist.—*Eng. Cyc.* Wight gives Diospyros Candolleana, 1221-22; capitulata, 1224-1558; chloroxylon, 1224; dubia, 1223; ebenum, 188; glutinosa, 843; Kaki, 415; montana, 1225; obovata, 1226; orixensis, 1225; ovalifolia, 1227; racemosa, 416; ramiflora, 189; tomentosa, fem. 183; tomentosa, mas. 182; and tetrasperma, 1221-22.

(3209) DIOSPYROS. Ebony. The Karens have distinctive names for four different species of ebony trees. The salt water swamp ebony, the water ebony, the yellow ebony, and the true ebony. Mr. Mason never met with the trees in flower, so as to be able to distinguish the species; but had seen specimens of the wood in the southern provinces, not inferior to the ebony of commerce.—*Mason.*

(3210) DIOSPYROS. Maulmain Ebony. An inferior kind of ebony is often seen at Maulmain, which the natives do not call by the same name that they do the trees which produce the good ebony, though evidently a product of the same genus. A similar wood at Tavoy is often denominated iron wood.—*Mason.*

(3211) DIOSPYROS CHLOROXYLON.

Nullaroolemara wood, Eng. | Nullaroolemara kurra, Tel.

(3212) DIOSPYROS DISCOLOR of the Philippine Islands also bears a fruit which is esteemed, and called *M*abolo.—*Eng. Cyc.*

(3213) DIOSPYROS CORDIFOLIA.

Vuckana Marum, Tam.

A hard heavy wood, colored dark brown; it is difficult to work. Wight No. 121.

(3214) DIOSPYROS EMBRYOPTERIS. Syn. Embryopteris glutinifera. D. glutinosoa, *Kon.*

Sindica. Sans. | Jumika. Tel.
Gaub. Hind. Beng. | Toombikai, Tam.

Fruit about two inches in diameter, green when ripe, and farinaceous externally. On being pressed, an excessively astringent juice exudes. This is so powerful that it generally yields on analysis 60 per 100 of pure tannic acid. It is used in medicine as a valuable astringent and styptic, and is employed in Bengal for paying the bottoms of boats. The bark has been

given with doubtful results in the treatment of intermittent fevers. See "*Extracts*" Pharmacopœia.—*O'Shaughnessy, page* 428. The fruit of the Diospyros embryopteris, the gab fruit, contains, when ripe, a great quanity of mucilage and tannic acid. The extract is reddish-brown in flexible plates, and if properly prepared, soluble in water. It is an excellent astringent, and very useful in diarrhœa and chronic dysentry. One to five grains of the Extract of Gab thrice daily. A solution 2 drams. in a pint of water is a valuable vaginal injection in leucorrhea.—*Beng. Phar. page* 290.

(3215) DIOSPYROS EBENASTER. Ainsl. Ebenaceæ, Icon. 188. Ebony.

Tookee, Tel.	Kakatatee, Tam.
Abnoos, Hind.	Acha Marum, Tam.

D. Ebenaster is a tree of considerable magnitude, a native of Ceylon, of which the leaves are coriaceous and smooth on both sides, and the buds smooth. This name is copied from Ainslie and there is still uncertainty whether this is the species that yields the ebony of the Palghaut jungles, as there is reason to believe that more than one species contributes wood black enough to pass current for ebony. The plant produced is Bauhinia tomentosa under that tamool name Acha marum, a widely different tree but having a very dark or black heart-wood.—*Wight.* Mr. Rhode mentions that Ebony of very superior quality is procurable in the hill Zemindaries of the Northern Circars particularly in the Ganjam District, he had received it from Goomsur furnishing 14 inch planks and of a fine uniform black. Inland from Ellore in the Masulipatam District he had likewise procured some of good size and quality; several logs of apparently younger wood yielded an ebony richly variegated with bright brown stripes and mottle—He knows not the tree from which the ebony of the Northern Circars is procured but has every reason to believe that it is procured from several varieties. Ebony is a wood much affected by the weather, a table of solid ebony exposed to the great heat of the land winds in the dry climate of Rajahmundry would have spaces of more than $\frac{1}{8}$ inch between the planks while in the subsequent monsoon the interstices would completely disappear. European cabinet makers seldom use ebony in plank solid, as after long seasoning it is liable to be affected by change of weather, this appears singular when it is remembered how much it is employed for instruments in which precision of extreme accuracy under great exposure is requisite, it is probable that it is only affected in the direction of its breadth. Too much weight however must not be allowed to the fact of its continued use by nautical and mathematical instrument makers, who largely use ivory, for scales, which is affected not only in its breadth but in length by change of temperature. The veined ebony is, he believes, the wood denominated "Coromandel" or "false Calamander." The Teloogoo term for Ebony is *Nalla Toomi* or *Toombi Kara, Toomi chava kara, Toombika* &c., the denomination varying in every district.—*Rohde.*

(3215) DIOSPYROS EBENUS.

Tendua, Hind.

The Ebony Tree, yielding a heavy black wood, grows abundantly in Ceylon and many parts of the Deccan.—*Riddell.* Dr. Irvine mentions that the tree, *Abnous*, the black heart, and *Tendua*, the white and spotted wood, is common in the Kotah jungles, especially near Gerdherpoora. The young trees yield a fine grained tough very hard wood: excellent for making hackeries &c. &c.: the ebony is not used: the very inferior fruit is eaten when rotted like the medlar.—*Gen. Med. Top. p.* 196. *D. Ebenus*, the True Ebony, and that which is considered to be of the best quality, is a large tree, a native of Mauritius, Ceylon, and apparently also of Madagascar; for *D. lanceolata*, Poir., collected by Commerson in that Island, is considered the same. The leaves are very smooth, short, petioled, alternate, bifarious, oblong in shape, the buds very hairy; male flowers sub-raceined, with about twenty anthers, the hermaphrodite solitary, obtandrous. Large quantities of the ebony of this species have been sometimes imported into Europe. Ebony is well known as a hard black-coloured wood, brought from the hot parts of the world. The Greek name is ἔβενος, from which the Latin *Ebenus* and our word Ebony have been immediately derived. It is first mentioned by Ezekiel, xxvii. 15, but in the plural, hobnem, where the men of Dedan are described as bringing to Tyre horns of ivory and of ebony. The Persian name, abnoos, is that by which it is commonly known all over India; it is probable therefore that the name, like the wood itself, had an eastern origin. From its hardness, durability, susceptibily of a fine polish, and colour, which has almost become another name for blackness, ebony has always been in high estimation, and in the present day is much used for mosaic work and ornamental inlayings, though cheaper woods dyed black or frequently substituted. Herodotus (iii. 97) mentions ebony as part of the presents brought in considerable quantities to the king of Persia by the people of Ethiopia. Dioscorides describes two kinds—one Ethiopian, which was considered the best; and the other Indian, which was intermixed with whitish stripes and spotted; and hence commentators have disputed whether there were one or two kinds of ebony. But the fact is that several trees yield this kind of wood, and all belong to the genus *Diospyros*. Owing to the known geographical distribution of this genus, the ancients must have derived their ebony either from the peninsula of

India, and the island of Ceylon, or by the coasting trade from Madagascar; for no species of *Diospyros* has yet been discovered by botanists in the upper parts of Egypt or in Abyssinia, though it is not improbable that some may be found, as the climate is well suited to their existence.—*Eng. Cyc. page* 356. The ebony of Mauritius is yielded by Diospyros ebenus, that of Ceylon is D. Ebenaster, while the ebony tree of the Coromandel coast is D. melanoxylon; other species, as D. tomentosa and D. Roylei, yield ebony on the continent of India. The tree yielding the African ebony is not ascertained. A kind of ebony, Amerimnum Ebenus, is produced in the West Indies, and called Jamaica ebony.—Mountain Ebony. The different species of Bauhinia are so called; B. porrecta grows on the hills in Jamaica, and has wood which is hard and veined with black.—*Tredgold. Holt.*

(3217) DIOSPYROS GLUTINOSA. TINDOOCA.

Gunb, SANS.	Pauniche marum, TAM.
Tumika, HIND. BENG.	

Diospyros glutinosa affords a fruit which, though edible, is far from palatable, but more valuable as an article of commerce. The tree is middle-sized, a native of the moist valleys amongst the mountains of the Circars, and all along the foot of the Himalayas to 30° N. lat. Sir William Jones first mentioned what is well known throughout Bengal, that the astringent viscid mucus of the fruit is used for paying the bottoms of boats. The unripe fruit contains a large proportion of tannin, and its infusion is employed to steep fishing-nets in to make them more durable.—*Eng. Cyc.* The wood is but of an indifferent quality and not much used, the ripe fruit is eaten by the Natives: it is strongly astringent; the unripe fruit contains a large proportion of tannin. An infusion is used to steep fishing nets to make them more durable. Roxb.—*Lokde, M.S S.*

(3218) DIOSPYROS KAKI, CHINESE DATES. *D. Kaki* is celebrated in China and Japan: specimens introduced into the Botanic Garden of Calcutta were found to be identical with others from Nepaul. The fruit is described by Dr. Roxburgh as being tolerably pleasant. It is esteemed in China, where it attains the size of an orange, and is frequently sent to Europe in a dried state, and called the Date-Plum of China, and also Keg-Fig of Japan.—*Eng. Cyc.* "The Burmese," says a correspondent who resided several years in Ava, "call the Chinese fig, which is brought in great quantities overland to Ava, *pe-thee* or *tay thee.*" This is the same fruit which in England is called Chinese date; but is neither fig nor a date, but the fruit of a species of ebony; and a more appropriate name would be the Chinese persimon, the persimon tree being also a species of ebony, and there is a considerable resemblance in the fruit. The tree which produces this "Chinese date," is occasionally cultivated by the Burmese, but it bears fruit very sparingly, and I think with Roxburgh, that it is "by no means equal to a good apple."—*Mason.*

(3219) DIOSPYROS MABOLA, (often called "mangosteen") under which name it is cultivated extensively in gardens at Vizagapatam.—*M. E. J. R.*

(3220) DIOSPYROS MELANOXYLON. *Ebenaceæ*, Roxb. c. 46.

Toombie marum, (ebony) TAM.	Ebony tree, ENG.
	Kendoo. BENG.

This plant grows in Coromandel, Malabar, Ceylon, and Midnapore Jungles. The bark is astringent, given by the native doctors with pepper in dysentery.—*O'Shaughnessy, page* 428. It is a very large tree, only the very heart of which is black, all the rest white. The white wood is however used for common purposes. The species of Diospyros have this peculiarity that the black heart wood is surrounded by white sapwood. There are several fine specimens of the genus.—*M. E. J. R. D. melanoxylon*, is described and figured by Rumph, iii., 'Corom. Plants,' 1 to 46, by Dr. Roxburgh, and is the Ebony-Tree of the Coromandel coast. It is found on the mountains of that coast as well as of Malabar and Ceylon. It grows to be very large, particularly the male tree of which the wood is also most esteemed. The leaves, which are sub-opposite, oval, oblong, obtuse, and villous, are deciduous in the cold season, the new ones appearing with the flowers in April and May; as in other species, it is only the centre of large trees that is black and valuable, and this varies in quantity according to the age of the tree. The outside wood, which is white and soft, time and insects soon destroy, leaving the black untouched. The ripe fruit is eaten by the natives, though rather astringent, as is also the bark. *D. tomentosa* and *D. Roylei* are other Indian species which yield ebony. Several species of the genus bear fruit, which, though clammy and sub-astringent, is eaten by the natives of the countries where the trees are indigenous. We need name only the most celebrated, as *D. lotus*, a native of Africa, and now common in the south of Europe, which bears a small yellow sweetish fruit about the size of a cherry, and which has by some been supposed to be the famous Lotus of the Lotophagi; but this is more likely to have been the Jujube, called by botanists *Zizyphus Lotus.—Eng. Cyc.* Diospyros Melanoxylon, or Ebony, Oukchiuya, *Burmese*, is found throughout the Pegu forests, seldom however of greater girth than three or four feet. It is very plentiful.—*McClelland.* The fruit of Diospyros Melanoxylon, Roxb. 46, is called Toombiee pullum Tam., Seneer Colbr. 86, and is eaten by the poor people.—*Ainslie, p.* 283.

(3221) DIOSPYROS MOLLIS, BLACK-DYE PLANTS.

Ma-klea, Burm.

The blossoms of the shoe-flower plant are used by the Chinese to dye leather black, the juice of the cashew-tree gives a black to linen, and the fruit of the melastoma affords a black dye. The celebrated vegetable dye the Shan black dye, is made from the fruit of this species of ebony, which is said to grow on the mountains that separate the Province of Tavoy from the Siamese territories. Isolated plants may be seen in the gardens of Tavoy, and Maulmain, but Mr. Mason has never seen one in flower, or fruit.—*Mason.*

(3222) DIOSPYROS MONTANA. Roxb. Yerragada is the Teloogoo name of a middle sized tree the timber of which Dr. Roxburgh informs us, is hard and durable and is variegated with dark and white coloured veins. —*Ains. Mat. Med. p.* 212.

(3223) DIOSPYROS RETICULATA, (*Tesselaria*, Poir.) is another elevated tree, a native of Mauritius, of which the heart-wood forms Ebony.

(3224) DIOSPYROS SAPOTA. Achras Sapota.

(3225) DIOPSIS, a genus of Dipterous Insects of the family Sepsidæ. The insects of this genus are remarkable for the immense prolongation of the sides of the head. The head itself is small, and appears as if it were furnished with two long horns, each having a knob at its apex; these horn-like processes however are not analogous to the parts usually termed antennæ, but are in fact prolongations of the sides of the head, the knob at the apex of each being the eye of the insect.—*Diopsis Sykesii*, of G. R. Gray, is one of the largest species of the genus, and possesses, the longest eye-stalks; these processes in this insect are of a pitchy red colour, and the body is the same tint. The head and thorax are ck, and the wings are coloured with brown. t little is known of the habits of these insects. onel Sykes, who collected great numbers of above species during his residence in India, nished Mr. Westwood with the following no- respecting their habitat and habits :—" Ha- at,—the hill fort of Hurreechunderghur, in western ghauts of the Deccan at an elevation 3900 feet above the level of the sea, 19° 23' lat, 70° 40' E. long."—*Eng. Cyc. Vol.* ii. *p.* 4.

(3226) DIPSACUS FULLONUM, TEASLE, FULLER'S THISTLE, is, according to yle, the *Dunsakoos* of the Indian Materia Me- a.—*O'Sh. page* 404.

(3227) DIPSAS (Laurenti), Bungarus (Op-), a genus of Serpents, placed by Cuvier un- the great genus Coluber. Body compressed, much less than the head; scales of the spinal row of the back larger than the others.

(3228) DIPSAS INDICA, Cuvier; Coluber Bucephalus, Shaw. Black, annulated with white. —*Eng. Cyc. Vol.* ii. *page* 430.

(3229) DIPTERACEÆ, OR DIPTEROCARPEÆ, *Dipterads*, an important order of East Indian Exogenous Polypetalous Trees. They have a tubular unequal permanent calyx, with five lobes, which after flowering become leafy and very much enlarged, surmounting the fruit without adhering to it. There are five petals, with a contorted æstivation, an indefinite number of awl-pointed narrow anthers, and a few-celled superior ovary, with two pendulous ovules in each cell; of these all are eventually abortive, except one, which forms the interior of a hard dry leathery pericarp. The seed is solitary, contains no albumen, and has an embryo with two large twisted and crumpled cotyledons, and a superior radicle. The leaves are long, broad, alternate, rolled inwards before they unfold, with strong straight veins running obliquely from the midrib to the margin, and oblong deciduous stipules rolled up like those of a *Magnolia*. The affinities of this order are with *Tiliaceæ* and *Corylaceæ* on the one side, and *Clusiaceæ* and *Ternstromiaceæ* on the other. The different species produce a number of resinous, oily, and other substances; one a sort of camphor [DRYOBALANOPS]; another a fragrant resin used in temples; a third, Gum Animi; while some of the commonest pitches and varnishes of India are procured from others. Ral, or Dhoona, a resin burned in the temples of India, is produced by *Shorea robusta*. Saul, the best timber in India, is furnished by the same tree. It contains 7 genera and 47 species.—*Eng. Cyc. p.* 353.

(3230) DIPTERIX ODORATA. TONKIN BEAN. Coumarouna odorata. A native of the woods of Guiana, used as a perfume for snuff.—*O'Shaughnessy, page* 304.

(3231) DIPTEROCARPUS, a genus of East Indian, and chiefly insular Trees, the type of the natural order *Dipteraceæ*. Blume gives the following essential characters :—" Calyx irregularly 5-lobed at the mouth; the two opposite segments very long and legulate; petals five, convolute when unexpanded; stamens numerous; anthers long, linear, terminating in an awl-shaped point; nut rather woody, and 1-celled and 1-seeded by abortion, inclosed in the enlarged calyx." The species are described as enormous trees, abounding in resinous juice, with erect trunks, an ash-coloured bark, strong spreading limbs, and oval leathery entire leaves, with pinnated veins. The flowers are large, white or pink, and deliciously fragrant. The pubescence is always stellate when present. The resinous juice of *Dipterocarpus trinervis*, a tree from 150 to 200 feet high, inhabiting the forests of Java, is made into

plaisters for ulcers and foul soles; and when dissolved in spirit of wine, or formed into an emulsion with white of egg, acts upon the mucous membranes in the same way as balsam of copaiva. *Dryobalanops Camphora*, the Camphor-Tree of Sumatra, is by some referred to this genus; but, according to Blume, is really a distinct genus.—*Eng. Cyc. page* 353. *Dipterocarpus lævis* and *turbinatus*. Dr. Helfer says that the oil of wood from these two species of dipterocarpus, or wood oil trees "laid upon paintings covers them with a transparent fine coating, not liable to turn yellow, and dries quickly." A few years ago Mr. Laidlay, the Secretary of the Bengal Asiatic Society, discovered that the oil of wood will dissolve caoutchouc. "The process adopted was simply to cut the caoutchouc into small pieces, and then drop a sufficiency into a bottle of the oil. In the course of a few hours the caoutchouc swells, and must then be frequently stirred to facilitate the process. If heat be applied, complete solution is speedily effected, but several days are required at the ordinary temperature of the atmosphere. The solution thus prepared may be spread on cloth, which is thereby rendered water-proof." Wood oil has been found to answer as a good substitute for fish oil in currying leather; and it is used for house varnish. Large quantities of this oil are used in the Tenasserim Provinces in the manufacture of torches, which emit a brilliant and durable light. A half dozen of these torches planted on an eminence make a splendid cresset, illuminating far over the plains. Speaking of these wood-oil trees, Dr. Wight remarks. "In this neighbourhood, Madras, several species are found, but all natives of hilly tracts forming the Balaghaut. In Pegu, where they abound, they occupy the plains."—*Mason.*

(3232) DIPTEROCARPUS. Sgau, *Burm.* Sour Wood Oil Tree. This is the name which the Karens give a large tree that grows on their mountains, but which produces comparatively very little wood oil.—*Mason.*

(3233) DIPTEROCARPUS ALATUS.

Aing, Burm.

This timber is called in Bengal "Battee Sal." It is excellent for every purpose of house-building, especially for posts. It is found chiefly to grow on laterite in the Tounghoo and Prome districts. Light-brown wood.—*McClelland.*

(3234) DIPTEROCARPUS GRANDIFLORUS, large flowered dipterocarpus. This is a species of wood oil tree which grows on the sandy plains near the sea-shore, and on a similar soil in the interior.—*Mason.*

(3235) DIPTEROCARPUS LÆVIS, *Hamilton. Syn.* D. turbinatus, Roxb.

Tilea gurjun, Beng.

A native of Chittagong, Pegu, Assam, Tippera, &c. The trunk grows to an immense size. This tree yields in abundance the thin balsam well known in all the Indian bazars, and called the gurjun or wood oil. To procure the balsam, Dr. Roxburgh informs us a large notch is cut in the trunk of the tree near the earth, where a fire is kept up till the wound is charred, soon after which the liquid begins to ooze out; a small gutter is cut in the wood to conduct the liquid to a receiver. The average produce is said to be 40 gallons in each season, during which it is necessary to cut off the charred surface from time to time, and burn it afresh. The process is performed during the cold season. The gurjun balsam varies in consistence from that of thick honey to a light oily liquid. The colour of a fine specimen of thick gurjun, obtained from Captain Jenkins of Assam, was a pale grey; specimens sent from Rangoon by Mr. Speir were a light brown. As found in the bazar this substance generally occurs as a brown, oily looking, semi-transparent liquid, in odour strongly resembling a mixture of balsam of copaiba with a small portion of naphtha. The essential oil, when freed from water by prolonged contact with dry chloride of calcium, and distilled a second time, is transparent and nearly colourless, of specific gravity 934, boils at 240°; it is soluble in alcohol, ether, naphtha, and the essential and fixed oils. It dissolves caoutchouc, copal, vateria resin, and solid gluten. Potassium and sodium retain their lustre in it, and undergo no change; the taste is acrid, sweetish, and heavy, its odour closely resembles that of the essential oil of copaiba. The close resemblance in the physical and chemical properties of this gurjun and copaiba balsam led to the institution of an extensive set of experiments by Dr. O'Shaughnessy on the medicinal effects of the former in the treatment of gonorrhœa. The results, which have been laid before the profession, and which have been confirmed by trials made by other practitioners, seem perfectly conclusive that, in the treatment of gonorrhœa, gleet, and similar affections of the urinary organs, the essential oil of gurjun is nearly equal in efficacy to the South American drug. The essential oil may be given in 10 to 30 drop doses in mucilage, milk, rice-water, or thin gruel, and repeated thrice, or still more frequently daily. It generally causes a sensation of warmth at the epigastrium, eructations, and sometimes slight purging. It communicates a strong smell of turpentine to the urine, which it increases remarkably in quantity. Some obstinate cases of chronic gonorrhœa and gleet, which had long resisted copaiba and cubebs, have been cured by this remedy in the course of the experiments alluded to. In the Pharmacopœia is given a formula for a solution of the essential oils of gurjun and cubebs in sulphuric ether, which affords a cheap, but perfectly efficacious substitute for the celebrated "Frank's Specific." Besides the above

species, the D. angustifolius of Wight and Arn. (D. costatus of Roxb. but not of Gaertn.), D. costatus, Gaertn. (D. incanus, Roxb.) and D. alatus, Roxb. of Pegu, afford this fluid in great abundance. Its price in the bazar ranges from 3 to 5 rupees the maund. Besides its use in medicine, it is likely to be found a perfect substitute in the arts for the expensive balsam of copaiba, now much used in the preparation of colourless varnishes and drying paints. In the coarser kinds of house and ship painting, gurjun balsum is used as an excellent substitute for linseed oil. Dr Wight and other writers speak confidently of the good effect of the gurjun oil mixed with dammar in preserving wood from the ravages of the white ant.—*O'Shaughnessy, pages* 222-224. *Dipterocarpus lævis*, the common wood oil tree produces a very useful timber, which is sawn into boards at Tavoy and Mergui, and used in house building. Where not exposed to the wet, they answer as well as teak, and are sold at half the price ; but they are not impervious to white ants.—*Mason.* Wood-oil, copaiva, of the *Dipterocarpus lævis*, is one of the most valuable products of the Tenasserim Provinces ; and the tree which produces the best quality is one of the most widely diffused of their forest trees. It yields too, very abundantly. Dr. Helfer wrote, that one trunk would produce thirty or forty gallons each season without injury to the tree. In the reports of the Agricultural and Horticultural Societies of India, it is said : "The wood-oil, properly speaking, is a balsam, obtained from several species of dipterocarpus common in many parts of India. By distillation this balsam yields volatile oil, a resin being left behind. This oil, Dr. O'Shaughnessy found to be identical in chemical composition with that of the balsam of copaiva, and he had accordingly used it extensively in his hospital, with exactly the same medicinal effects." "Nor is this article," continues the report, "likely to become of importance in medicine only ; but also in the arts, in many of which copaiva is now used. Copaiva, by the latest 'day price current,' was at five shillings and six pence the pound, while twenty pounds of the essential oil of wood may be obtained, of the very best quality, for about ten shillings."—*Mason.*

(3236) DIPTEROCARPUS TURBINATUS,

Sitgurjun, Beng. | Kauyeen, Burm.

A native of Chittagong, Tipperah, Pegu &c., to the eastward of Bengal where it grows to be an immense tree. This tree is famous all over the Eastern parts of India and the Malay islands, on account of its yielding a thin liquid balsam, commonly called wood oil. To procure the balsam a large notch is cut into the trunk of the tree about thirty inches from the ground, where a fire is kept up until the wood is charred, soon after which the liquid begins to ooze out : a small gutter is cut in the wood to conduct the liquid into a vessel placed to receive it. The average produce of the best trees during the season is said to be sometimes forty gallons. It is found necessary every week to cut off the old charred surfaces and burn it afresh. In large healthy trees abounding in balsam they even cut a second notch in some other part of the tree and clear it as at first : these operations are performed during the months of November, December, January, and February ; should any of the trees appear sickly the following season, one or more years respite is given them. Roxb. The D. costatus, a native of the coast South of Chittagong where it is called Tileyagurjum, the 'Dincanus gurjun' of Chittagong, "Dalatus" of Pegu and Mascal island, also yield the oil. Roxb.—*Rohde M.S.S.* At Hazaree ke hath, in Chittagong, 100 feet above the level of the sea, large myrtaceous trees are common, and show a tendency to the Malayan flora, which is further demonstrated by the abundance of Gurjun (*Dipterocarpus turbinatus*). This is the most superb tree we met with in the Indian forests : we saw several species, but this is the only common one here ; it is conspicuous for its gigantic size, and for the straightness and graceful form of its tall unbranched pale grey trunk, and small symmetrical crown : many individuals were upwards of 200 feet high, and fifteen in girth. Its leaves are broad, glossy and beautiful, the flowers (then falling) are not conspicuous ; the wood is hard, close-grained, and durable, and a fragrant oil exudes from the trunk, which is extremely valuable as pitch and varnish, &c., besides being a good medicine. The natives procure it by cutting transverse holes in the trunk, pointing downwards, and lighting fires in them, which causes the oil to flow.—*Hooker, Him. Jour. Vol.* II. *p.* 348. This tree furnishes timber of great size and strength. It is fit for any purpose for which Saul is employed, being of the same family. It is chiefly employed for canoe and boat building. It is found in all the forest districts, except Prome, where it is scarce. Wood, light-brown—*McClelland. Wood Oil* Kauyinsee is afforded by, and largely extracted from, *Dipterocarpus turbinatus*. It is one of the largest trees known. It is found throughout the southern as well as all the Sitang forests, disappearing curiously enough wherever the *Acacia Catechu* appears. Thus, where the latter is in perfection, in the northern part of the Tharawaddy and Prome distrcts, the wood-oil tree is rarely seen, and where the latter is found in perfection, as in the Southern forests and throughout the forests of Tounghoo, west of the Sitang, there is no *Acacia Catechu*. The wood-oil tree grows in light sandy soil, near the banks of streams, and in dense forests ; frequently attaining 18 feet in girth, with a proportionate height. The oil is extracted by cutting a large notch in the tree, a few feet from the ground,

ınd occasionally stimulating the secretion by corching the surface of the scar, which is gene- ally converted into charcoal and gives the oil a lirty black appearance.—*McClelland.*

(3237) DIRISANA GUM. The *Acacia si-issa* yields a large quantity of this clear gum. —*M. E. J. R.*

(3238) DIVI DIVI. See Cæsalpinia Co- ıiaria.

(3239) DIVI LADNER, the forbidden fruit ıf the Ceylonese. It is produced by a species of *Tabernæmontana.*—*Eng. Cyc. Vol.* ii. *p.* 365.

(3240) DISTILLED WATERS. Contain a ittle of the volatile principles of plants, and may ıe distilled either off the plants, or by distilling ome Essential Oil with water.—*Eng. Cyc.* The ıllowing waters may be made by using 2 lbs. of ıesh or 4 lbs. dried leaves to two gallons of vater; of the seeds, one pound.

(3241) DOCKS. Docking of vessels. Along ;he greater part of the Eastern coast, of the Peninsula of India, wherever the rivers can be entered by coasting craft, docks are formed by digging a channel from the river sufficiently large to allow the vessel to be floated into it at high water: a dam is thrown across the channel and the earth being thrown into the dock thus formed the vessel is floated up above the water mark. By draining off the water the vessel is left high ınd dry imbedded in earth. This is removed to ıllow of access to the bottom of the vessel which s propped up by stones, it is usual also to place ogs under the keel. A dry dock is thus formed .bout the vessel at a small expense. The repairs ıaving been executed, it becomes necessary to ower the vessel down to that point when, the lam being removed and the water let in, she can ıe floated out. For this purpose cables are coil- ;d under her and these coils filled in with earth, ;he earth under the vessel and logs which were ılaced under her keel removed, the dock is dug ıut to its former depth, the vessel is left sus- ıended resting on the keel, by uncoiling the ables gradually the vessel is let down and is hen floated out. Ships of 400 tons are thus locked at Coringa.—*Rohde, M.S.S.*

(3242) DOCKET. This term has various meanings. In trade it is often applied to a short certificate, summary, or memorandum; and in English Law it signifies a brief in writing.—*Faulkner.*

(3243) DODDERS, Cuscuta, covered even tall trees, in the Soane valley with a golden web. —*Hooker, Him. Jour. page* 38.

(3244) DODECATHEON MEADIA, Primulaceæ. Ornamental plants, when in flower, colours, lilac, purple and white, grown in a light soil and cultivated by dividing the roots.—*Riddell.*

(3245) DODONEA VISCOSA, common on the Neilgherries: wood elastic and useful for tool handles.—*McIvor.*

(3246) DOGBANES (*Apocynaceæ*). Among this division of plants there are some which are most conspicuous for the strength of their fibres. These belong to two families of plants which are so nearly allied to each other, that they were united together by the celebrated Jussieu. Both are remarkable for abounding in milky juice; and some of them in caoutchouc, or some analogous products. Of these, the Apocynaceæ or Dogbanes are composed chiefly of trees and shrubs, of which the Oleander is a conspicuous example. But some are herbaceous, as in the case of the Vinca, or Periwinkle as it is called, which shows another characteristic, that is, the climbing habit of many of these plants, as well as the toughness of their fibre, as may easily be ascertained by trying to break any of the long, trailing twigs of this plant, so common in gardens and shrubberies. Among these, is a plant called *Nerium piscidium*, by Dr. Roxburgh, ' Fl. Ind.,' ii, p. 7, common in the Khasya or Silhet Mountains, and there called *Echalat.* It there forms an extensive perennial climber. Its bark contains a large quantity of fibre, which the natives use for the same purposes as Hemp. Dr. Roxburgh, in steeping some of the young shoots in a fish-pond, in order to facilitate the removal of the bark and to clean the fibres, found that many, if not all the fishes, were killed. Hence the specific name which he applied. Dr. Wight has formed the plant into a new genus, Echaltum. It is probable that there are many other fibre-yielding plants in this and the next family among the climbing species.—*Royle, Fib. Pl. page* 302. The *Asclepiads* (*Aclepiadeæ*).—Closely allied to the *Apocynaceæ* is the family of plants which has been named *Asclepiaceæ* and *Asclepiadeæ*, from the genus *Asclepias*, to which most of the species formerly belonged. Among these, there are several remarkable for their fibrous properties, and many more probably remain to be discovered. Though many of this family of plants abound in the hottest and moistest parts of the world, others are also found in the driest and most barren parts of Asia, with a few species ex-

tending even to the North of Africa and to the South of Europe, Siberia, North America, and Japan; and southwards, to the Cape of Good Hope and New Holland. The great majority are distinguished by their twining habit; though their flowers are often inconspicuous, their seed-vessels are remarkable for being in pairs, and which, on bursting, display a quantity of thistle-like down attached to each seed, which floats them about as those of thistles and dandelions. This down may no doubt be turned to some useful purposes, and therefore makes the plants abounding in fibre more valuable, as thus yielding a double product; though it is probably only in dry and barren parts of a couutry, that it would be desirable to attend to these, instead of to the numerous other fibrous plants which may either be more easily cultivated, or the fibre separated with greater facility.—*Royle, Fib. Pl. p.* 303.

Syrian Dogbane, Asclepias syriaca (*Asclepiadeæ*). *Syrian Dogbane—Jetee Fibre.* Of the plants of this family, useful both for its down and for its fibrous stem, we may first mention that called Syrian Dogbane, which, although a native of the burning plains of Syria, will grow in colder climes, and is indeed cultivated as far north as Upper Silesia. It is easily propagated either by seed, or by parting the roots. The plants thrive luxuriantly in light soil, but will flourish on any poor land. The silk-like down which surmounts the seed of this plant, is not more than an inch or two in length; but it has, nevertheless, been usefully applied for articles of dress manufactured of it both in France and in Russia. The fibres of the stem, prepared in the same manner as those of Hemp and Flax, furnish a very long fine thread of a glossy whiteness.—*Royle, Fib. Pl. p.* 709.

(3247) DOMBE. A soft, coarse, open-grained, light Ceylon wood, bearing a strong resemblance to inferior Honduras mahogany, takes a good polish, and presents a pretty, curled pattern; but judging from this specimen, which is much worm-eaten, it cannot be a very durable wood, at all events in its native country.—*Ex. p.* 1851.

(3248) DOMBEYA, a genus of Plants belonging to the natural order *Byttneriaceæ*, inhabiting the East Indies and the isles of France, Bourbon, and Madagascar. They have a 5-parted persistent calyx, surrounded by a 3-leaved unilateral involucel. The petals are 5. The stamens are from 15 to 20, scarcely monadelphous, five of them being sterile, with from 2 to 3 fertile ones between each sterile stamen. The name *Dombeya* was also applied to the plant now called *Araucaria excelsa*. The bark of *D. spectabilis* is made into ropes in Madagascar.—*Engl. Cyc. p.* 885.

(3249) DOMBEYA ANGULATA. A shrub; leaves cordate, acuminate, and serrate; old ones three or five-angled; flowers in corymbs, of a pretty rose colour.—*Riddell.*

(3250) DOMBEYA PALMATA, BYTTNERIACEÆ. A shrub; leaves palmate, resembling the common castor oil plant; flowers, in large terminal corymbs, rose coloured, appear in September and October.—*Riddell.*

(3251) DOMBEYA SPECTABILIS. In Madgascar, the bark of *Dombeya spectabilis* is made into ropes.—*Engl. Cyc. page* 708. In its more extended relations, the natural family of *Byttneriaceæ*, includes such genera as *Bombax, Sterculia, Abroma, Guazuma*, &c., and like that of the Mallow-worts, inhabits hot parts of the globe chiefly, and also, like it, contains a number of plants remarkable for abounding in mucilage and in fibrous bark. Of these some are employed for cordage in different parts of the world, and of them a few, as *Abroma augusta*, might probably be grown with greater profit, and yield a better product, than some of those which are now in cultivation.

(3252) DOMBEYA TOMENTOSA. A small tree with rose-coloured flowers, but smaller than the above two species.—*Riddell.*

(3253) DOMETT. A thin kind of flannel, of which the weft only is wool, the warp being composed of cotton.—*Faulkner.*

(3254) DOOM, OR DOUM, a remarkable Palm-Tree exclusively inhabiting Upper Egypt, especially the neighbourhood of Thebes, whence it is named *Cucifera Thebaica.* Its stem, instead of growing without branches like other palms, forks two or three times, thus assuming the appearance of a Pandanus. Clumps of it occur near Thebes. The fruit is about the size of an orange, angular, irregularly formed, of a reddish colour, and has a spongy, tasteless, but nutritious rind. The albumen of the seed is hard and semi-transparent, and is turned into beads and other little ornaments. Gærtner described it under the name of *Hyphæne coriacea.* It is known in Egypt as the Gingerbread-Tree, because of the resemblance of its brown mealy rind to that cake.—*Eng. Cyc. page* 385.

(3255) DOOPADA RESIN, exudes from the *Vateria Indica*, and constitutes the piney varnish. The resin is used as a fragrant incense in temples, the quantity procurable is very considerable.—*M. E. J. R.*

(3256) DOOPUTTAHS. These cloths are manufactured at various places and of different qualities and colours. Those brought from Benares are always with gold and plain lace borders of different sorts, are sold at from 25 to 350 Rupees each. Those of Arnee in the Collectorate of Chingleput, with borders of yellow cotton, are priced at from Rupees 2 to 7 each and those of Ooppada in Rajahmundry are woven with white borders and are sold at from 1½ to 3 Rupees each.

(3257) DOREMA, a genus of Plants belonging to the natural order *Umbelliferæ*. It has an epigynous cup-shaped disc; the fruit slightly compressed from the back, and edged; 3 distinct filiform primary ridges near the middle, and, alternating with them, 4 obtuse secondary ridges, the whole enveloped in wool; vittæ 1 to each secondary ridge, 1 to each primary marginal ridge, and 4 to the commissure, of which 2 are very small.—*Eng. Cyc. page* 385.

(3258) DOREMA AMMONIACUM. (Don.) *Linn. Trans.* xvi. 601.

Oshak, Pers.

Is a glaucous green plant with a perennial root, large leaves 2 feet long, somewhat bipinnate, the pinnæ in three pairs, the leaflets incisо pinnatifid, with oblong mucronulate entire or slightly-lobed segments from 1 to 5 inches long and half an inch to 2 inches broad: the petiole very large, downy, and sheathing at the base; the teeth of the calyx acute, membranous, minute; the petals ovate, reflexed at the point; the fruit elliptical, compressed, surrounded by a broad flat edge. This plant is a native of Persia, in the plains of Yerdekhast and Kumisha in the province of Irac; and near the town of Jezud Khast in very dry plains and gravelly soil, exposed to an ardent sun. This plant is one of those which yields gum ammoniacum, but it is probable that there are several species of plants which yield this as well as the other gum-resins of the order *Umbelliferæ*. (Lindley, *Flora Medica.*)—*Eng. Cyc. page* 355. The stem and fruits yield abundance of Ammoniacum resin.—*O'Sh. page* 364. This gum resin is imported into Bombay from the Persian Gulf, and re-exported to different countries. —*Faulkner*. It is obtained by incisions in the plant, and occurs in two forms,—first in voluminous masses of yellowish colour, enclosing white almond-like tears, the whole being of plastic consistence, and very impure;—secondly, in tears of irregular form, white or yellowish, opaque, rather solid, agglutinated or distinct, compact, brittle, of glassy fracture, and free from impurities. Its odour is faint and peculiar, taste sweetish and then bitter. It is partially soluble in water, ether, alcohol, alkaline solutions and acetic acid. Its *Medical effects*, are similar to, but less powerful than asafœtida. It is principally employed as an expectorant in the chronic catarrhs and asthmas of old persons. It is also applied externally as a warm and stimulating plaster.—*O'Shaughnessy, page* 365.

(3259) DOLICHOS. Under this name Linnæus included the greater part of those tropical twining Leguminous Plants which bear eatable fruit like the kidney-beans cultivated in Europe. A large number of species, ill distinguished from each other, and differing materially in the structure of their fructification, were for so long a time collected under this name that, although they are now broken up into several genera, we shall briefly notice the more remarkable in this place.

a. Dolichos itself is confined to the species with a compressed linear pod, having incomplete cellular dissepiments, and ovate seeds with a small oval hilum. Of these *D. Catiang*, the pulse of which is called Boberloo in India, is an annual, and has somewhat deltoid leaves, angular at the back, few-flowered peduncles, and erect pods. It is cultivated in the fields in many parts of India during the dry season, and its seeds are extensively consumed by the poorer natives. *D. lignosus*, a perennial, with long racemes of flowers, broad heart-shaped leaflets, and linear sharp-pointed pods, is extremely common all over India, where it is cultivated "during the cold season in gardens and about the doors of the natives, forming not only cool shady harbours, but furnishing them with an excellent pulse for their curries," &c. There are several varieties of it, constituting the commonest kidney-beans of India. *D. biflorus*, an annual, with oblong pointed leaflets and scimitar-shaped hairy pods, furnishes the pulse called in India Horse-Gram; and *D. sphærospermus* produces the Calavana or Black-Eyed Peas of Jamaica.

b. Lablab has a compressed scimitar-shaped pod, rough, with tubercles at the sutures, and furnished with transverse imperfect cellular partitions, and ovate seeds with a fungous callous linear scar. *Lablab vulgaris*, the old *Dolichos Lablab*, is a common plant in the hedges in many parts of India, whence it has travelled into the tropical parts of America. It is a smooth perennial, with showy white or purple flowers, and large horizontal pods, containing from three to four seeds. It has a heavy disagreeable bug-like smell, prefers a rich black soil that cannot be flooded by rains, and produces a coarse but wholesome pulse, much eaten by the lower classes in India.

c. Pachyrhizus has a long compressed pod, with kidney-shaped seeds and no dissepiments, and is remarkable for its principal species, *P. angulatus* (formerly *Dolichos bulbosus*), producing a root of the size and substance of a turnip. It is reported to have been carried to the Philippines from South America, and thence to have been introduced into the west of Asia. The side leaflets are nearly triangular, that in the middle lozenge-shaped, slightly toothed, and shaggy on both sides. The flowers are very beautiful, of a violet-blue colour, and arranged in axillary, nearly erect racemes, from one to two feet long. Its root is a common article of food in the Malay Archipelago, but no other part of the plant is eaten.

d. Psophocarpus. The pods are oblong, and have four longitudinal wings; the seeds are roundish. It comprehends the *Dolichos tetragonolobus*, a twining annual, the pods or tuberous roots of which are a common Indian esculent.

e. Canavalia, with long straightish compressed pods, having three short wings at the lower suture, cellular dissepiments, and oblong seeds with a narrow hilum, comprehends the South American Lima Beans and the Sword Beans of India. The species have a handsomer and firmer foliage than the other genera, and the flowers are usually large and showy. *C. gladiata* the common cultivated species, has often pods two feet long, and varies with red, gray, and white seeds. Finally, the genus,

f. Mucuna, known by its oblong, puckered, compressed, hispid pods, includes all the species from which Cowage is obtained.—*Eng. Cyc.*

(3260) DOLICHOS BIFLORUS.

Hurali, CAN.	Ulavalu, TEL.
Kulthi, HIND. and MAH.	Horse Gram, ENG.
Kollu, TAM.	

Is largely grown every where in Mysore; and much of it is exported to the Neilgherries.

Its Oil.

Moneela gram oil, ENG.	Varcadalai yennai, TAM.
Varoosanigaloo nuna, TEL.	

A pale yellow clear oil is obtained from the seed of Dolichos biflorus (?). Oil is also expressed in India from the seed of the Argemone mexicana, which is used for lamps and in medicine; and from the seeds of the cashew nut (Anacardium occidentale), from Sapindus marginatus, and the country walnut (Aleurites triloba). The fruit of the Chirongia sapida, (or Buchanania latifolia,) yields oil.

(3261) DOLICHOS BULBOSUS, Roxb. INGOMAAS. (*Manill.*) Pachyrhizus.

Ingomaas is the Manilla name of a plant which appears in Rumphius under the appellation of Cacara Bulbosa, and to which Roxburgh has given the Botanical term of Dolichos Bulbosus. It is now cultivated in Bengal, for its edible root, and was formerly introduced into the Missionary Garden at Tranquebar, by that excellent Botanist Doctor Klein, who believes that it is the plant which has been called by the English on the island of Nevis, the Turnip-tree. Rumphius says of it that its root, properly prepared, has been considered, in Amboyna, as a great delicacy.—*Ainslie, page* 249.

(3262) DOLICHOS CATIANY. Lin.

Caramunny keeray, TAM.	Lasunda, SANS.
Lobeh ke baujee, DUK.	Lobeah, HIND.
Caramunny pyre, TAM.	Alasendi, MALAY.
Chora, GUZ.	Tadagunny, CAN.
Lobeh, DUK.	Lasunda, SANS.
Duntoo Pesaloo, TEL.	

This also is a valuable pulse, much prized by the Indians. It would appear by Link's Travels, that it is cultivated in Portugal.—*Ainslie, page* 237.

(3263) DOLICHOS CULTRATUS. Thunb. Huzar Bean.

Tambatangai, TAM.	Bara mareca HORT. MAL.
Kursambul ke pullie, DUK.	Kosopulla, SANS.
Tammakaia, TEL.	

This very large hanger shaped legume when young, is eaten entire: when full grown the seeds only are used.—*Ainslie, page* 245.

(3264) DOLICHOS ENSIFORMIS.

Tbumbatun-koy, TAM.

A species of bean which climbs to a great distance. The pods are used as a substitute for French beans; before cooking, they are cut into thin slices. It is commonly cultivated; require very strong stakes. D. uniflorus and D. sinensis are cultivated for the same purpose.—*Jaffrey.*

(3265) DOLICHOS FABAEFORMIS. Lin.

Cott Averaykai, TAM.	Mutkeke pullie, DUK.
Guvarphalli, GUZ.	Goroochikoodikaia, TEL.

This legume, which is about three or four inches long, is the produce of a plant of the class Diadelphia and order Decandria, and is much prized by the natives.—*Ainslie, p.* 239.

(3266) DOLICHOS, LEGUMINOSÆ. DOLICHOS LIGNOSUS. These are twining plants. Natives of India and grow in any good soil.

(3267) DOLICHOS PILOSUS. WILD DOLICHOS. An indigenous species of dolichos with downy leaves and pods, abounds in some sections of Tenasserim.—*Mason.* In Japan a kind of butter, called mijo, is obtained from a species of the dolichos bean (Dolichos soja).—*Simmonds.*

(3268) DOLICHOS SINENSIS. LOOBEA. Asparagus Bean. This bean is sown at the commencement of the rains; it has a very long and slender pod, and is boiled and eaten as French beans; the bean itself is small.

(3269) DOLICHOS SPICATUS.

Avere, CAN.	Anumula, TEL.
Bullar, HIND.	Motche, TAM.
Val, MAH.	

This grain as above explained, is grown along with Ragi, and is used in food along with Ragi. It does not keep well, unless great care is taken in packing it in parcels, or in fact as some of the Ryots do, in placing Avere in the heart of the Ragi in caves, when it will keep good for some years. This pulse, when green, is used as a vegetable, and cattle are generally fed on the grain when dry. It is not largely exported beyond Mysore.

(3270) DOLICHOS TRANQUEBARICUS. Lin.

Pytungai, TAM.	Pesalakaia, TEL.
Lobeh ke pullie, DUK.	Rajamasha, SANS.

This is a long, slender, pleasant tasted legume, not unlike our French bean both in appearance and natural qualities. There is a larger variety of it called in Tamool, Perumpytungai; in Dukhanie, Suffaid Lobeh ka pullie; in Telingu, Duntoo

Pesalakaia, and in Sanscrit, Sveta Rajamasha.—*Ainslie p.* 244.

(3271) DOLICHOS UNIFLORUS. Lin. Variety Black Gram, Madras Horse Gram, Glycine tomentosa.

Cooloo, TAM.	Huruli, CAN.
Kulti, GUZ.	Maediree, MAL.
Kooltie, DUK.	Coolootu, SANS.
Woolavoolu, TEL.	

This is the common food of horses on the coast of Coromandel. It is a very pleasant tasted pulse, and is used by the lower classes as an article of diet.—*Ainslie, p.* 238.

(3272) DOSIA POWDER, The Japanese have a method of interment peculiar to themselves. Instead of enclosing corpses in coffins of a length and breadth proportionate to the stature and bulk of the deceased, they place the body in a tub, three feet high, two feet and a half in diameter at the top, and two feet at the bottom. It is difficult to conceive how the body of a grown person can be compressed into such a space, when the limbs, rendered rigid by death, cannot be bent in any way. The Japanese, to whom Fitsingh made this observation, told him, that they produced this result by means of a particular powder called dosia, which they introduced into the ears, nostrils, and mouth of the deceased, after which the limbs all at once acquired astonishing flexibility. As they promised to perform this experiment in his presence, he remarks, "I could do no other than suspend my judgment, lest I should condemn as an absurd fiction a fact which, indeed, surpasses our conceptions, but may yet be susceptible of a plausible explanation. The experiment accordingly took place in the month of October, 1783, when the cold was already pretty severe. A young Dutchman having died in the island of Desima, I directed the physican to cause the body to be washed and left all night, exposed to the air, on a table placed before an open window, that it might become completely stiff. Next morning, several Japanese, some of the officers of the factory, and myself, went to examine the corpse, which was as hard as a piece of wood. One of the interpreters, named Zenby, drew from his bosom a santook, or pocket-book, and took out of it an oblong paper full of a coarse powder resembling sand: this was the famous dosia powder. He put a pinch into the ears, another into the nostrils, and a third into the mouth, and presently, whether from the effects of this drug, or of some trick which I could not detect, the arms, which had before been crossed over the breast, dropped of themselves, and in less than twenty minutes, by the watch, the body recovered all its flexibility. I attributed this phenomenon to the action of some subtle poison, but was assured that the dosia powder, so far from being poisonous was an excellent medicine in difficult labours. In such cases, a cup of hot water, in which a little of the dosia powder, tied in a bit of white rag, has been infused, is adminstered to the patient, who is then sure to obtain a safe and speedy delivery. The dosia powder is likewise recommended as the most efficacious remedy for diseases of the eyes. An infusion of this powder, taken even in perfect health, is said to have virtues which cause it to be in great request among the Japanese of all classes. It cheers the spirits and refreshes the body. It is carefully tied up in a piece of white cloth and dried, after being used, as it will serve a great number of times. The same infusion is given to people of quality when at the point of death: if it does not prolong life, it prevents rigidity of the limbs; and the body is not exposed to the rude handling of professional persons—a circumstance of some consequence in a country where respect for the dead is carried to excess. I had the curiosity to procure some of this powder, for which I was obliged to send to Kidjo, or the nine provinces, to all the temples of the Singous, which enjoy the exclusive sale of it, because they practise the doctrine of Kobou-Daysi, its inventor. It was after the death of this Kobou-Daysi, in the second year of the nengo-zio-wa (A. D. 825), that this sand came into general use in Japan. The quantity obtained in consequence of this first application was very small, and even this was a special favour of the priests, who otherwise never part with more than a single pinch at a time. At my departure in 1784, however, I carried with me a considerable quantity of the dosia powder. Part was put up in lots of twenty small packets each, with the name written on the outside in red characters, the rest was in small bags: this was only a coarse powder, in which were to be seen here and there particles of gold, and which probably was not yet possessed of the requisite virtues. One small packet only had undergone the chemical operation which ensures its efficacy, and this was a powder as white as snow. The discovery of the dosia powder is ascribed to a priest named Kobou-Daysi: he became acquainted with the properties of this valuable mineral on the mountain of Kongosen, or Kimbensen, in the province of Yamotto, where there are many mines of gold and silver, and carried a considerable quantity of it to the temple to which he belonged, on the mountain of Kojas-an. The priests of this temple continue to chant hymns of thanksgiving to the gods who led Kobou-Daysi to this important discovery. When their stock is exhausted, they fetch a fresh supply from the mountain of Kongosen, and carry it away in varnished bowls. In all ages the common people are apt to attribute phonomena surpassing human comprehension to the agency of celestial spirits; and, accordingly, the priests do not fail to pretend that the dosia powder owes all its efficacy to the

favour of their prayers. As soon as the new supply arrives, it is put into a basin, varnished and gilt, and set before the image of the god, Day-nitsi or Biron-sanna. The priests, ranged in a circle before the altar, and turning between their fingers the beads of a kind of rosary, repeat for seven times twenty-four hours a hymn called Onomio-Singo, the words of which are:—

> Or o bokja Biron sanna nomaka fodora mani
> Fando ma, zimbara fara, fare taja won.

The priests assert, that, after this long exercise, a kind of rustling is heard in the sand; all the impure particles fly out of the vessel of themselves, and nothing is left but the purified dosia powder, which is then divided among all the temples of the Singous.—*Titsingh's Illustrations of Japan, p.* 283. Instead of enclosing the bodies of the dead in coffins of a length and breadth proportionate to the stature and bulk of the deceased, they place the body in a tub, three feet high, two feet and a half in diameter at the top, and two feet at bottom. It is difficult to conceive how the body of a grown person can be compressed into so small a space, when the limbs, rendered rigid by death, cannot be bent in any way. The Japanese, to whom I made this observation, told me that they produced the result by means of a particular powder called Dosia, which they introduce into the ears, nostrils, and mouth of the deceased, after which the limbs all at once, acquire astonishing flexibility. I attributed this phenomenon to the action of some subtle poison, but was assured that the Dosia powder, so far from being poisonous, was a most excellent medicine in child bearing, for diseases of the eyes, and for other maladies. An infusion of this powder, taken even in perfect health, is said to have virtues which cause it to be in great request among the Japanese of all classes. It cheers the spirits and refreshes the body. It is carefully tied up in a white cloth and dried, after being used, as it will serve a great number of times before losing its virtues. "The same infusion is given to people of quality when at the point of death; if it does not prolong life, it prevents rigidity of the limbs; and the body is not exposed to the rude handling of professional persons, a circumstance of some consequence in a country where respect for the dead is carried to excess. Titsingh, however, obtained a considerable quantity afterwards, which he carried home with him in 1784. It has the appearance of sand, and when it is fully perfected for use is as white as snow. It is obtained on the mountain of Kongosen or Kinbeusen in the province of Yamatto, where there are many mines of gold and silver. The process by which it is prepared is the secret of the priests. Their knowledge is doubtless the result of accidental experience, for their acquaintance with chemistry is so light that we may safely conclude they do not understand the rationale of its preparation.—*American Expedition to Japan, page* 72.

(3273) DRACÆNA, a genus of Endogenous Plants of the natural family *Asparageæ* of Jussieu, now arranged as a section of *Liliaceæ* by Dr. Lindley. The genus was established by Linnæus, and named from one of its species yielding the resinous exudation, familiarly known by the name of Dragon's Blood, a translation of the Arabic name Dum al Akhwain, met with in Avicenna and other Arabian authors. *Dracæna* is characterised by having an inferior 6-partite perianth, of which the segments are nearly erect, and have inserted on them the 6 stamens, with filaments thickened towards the middle and linear anthers. The style is single, with a trifid stigma. The berry 2 or 3-celled, with its cells 1 or 2-seeded. The species of *Dracaena* are now about 30 in number, and found in the warm parts of the Old World, and in many of both Asiatic and African islands, whence they extend southward to the Cape of Good Hope and Australia, and northward into China; and to the eastern parts of India, as the districts of Silhet and Chittagong. Species are also found in Socotra, and the Canary and Cape Verd Islands, as well as at Sierra Leone. From this distribution it is evident that the species require artificial heat for their cultivation in England. They are found to thrive in a light loam, and may be grown from cuttings sunk in a bark bed. The species of *Dracaena* are evergreens, either of a shrubby or arboreous nature; and having long, slender, often columnar stems, they emulate palms in habit. Their trunks are marked with the cicatrices of fallen leaves; the centre is soft and cellular, having externally a circle of stringy fibres. The leaves are simple, usually crowded together towards the end of the branches, or terminal like the inflorescence; whence we might suppose that the name *terminalis* had been applied to some of the species, if Rumphius had not stated that it was in consequence of their being planted along the boundaries of fields. The structure of the stem and leaves is particularly interesting, as the fossil genera *Clathraria* and *Sternbergia* have been assimilated to *Dracaena*, the former by M. Adolphe Brongniart, and the latter by Dr. Lindley; and as Rumphius compares the leaves of a *Dracaena* with those of *Galanga*, it is as probable that the fossil leaves called *Cannophyllites* may be those of a plant allied to *Dracaena*, as that they belong to one of the *Cann*. Of the several species of *Dracaena* which have been described by botanists, there are few which are of much importance either for their useful or ornamental properties. Among them however may be mentioned *D. terminalis*, a species rather extensively diffused. The root is said by Rumphius to be employed as a demulcent in cases of diarrhœa, and the plant as a signal of truth and of peace in the Eastern

Archipelago. In the islands of the Pacific Ocean a sweetish juice is expressed from its roots, and afterwards reduced by evaporation to a sugar, of which specimens were brought to Paris by Captain D'Urville from the island of Tahiti (Otaheite). The root is there called Ti or Tii, and thence no doubt corrupted into Tea-Root by the English and Americans. M. Gaudichaud mentions that in the Sandwich Islands generally an intoxicating drink is prepared from this root, to which the name Ava is often applied, as well as to that made with the roots of *Piper methysticum*. —*Eng. Cyc.*

(3274) DRACÆNA. The singular red leaved Chinese iron-wood is a member of the Liliaceæ; it is chiefly noticeable for its long red leaves.—*William's Middle Kingdom, p.* 279.

(3275) DRACÆNA ATROPURPUREA. DRAGON TREE. Two or more species of the dragon tree, resembling small areca palms are seen in Burmese compounds, but the most common is the one with dark purple leaves.—*Mason.*

(3276) DRACÆNA DRACO is the best known species, not only from its producing Dragon's Blood, but also from one specimen having so frequently been described or noticed in the works of visiters to the Canary Islands. The erect trunk of the Dragon-Tree is usually from 8 to 12 feet high, and divided above into numerous short branches, which terminate in tufts of spreading sword-shaped leaves, pointed at the extremity. The most celebrated specimen of this tree grows near the town of Orotava, in the island of Teneriffe, and was found by Humboldt in 1799 to be about 45 feet in circumference. Sir G. Staunton had previously stated it to be 12 feet in diameter at the height of 10 feet; and Ledru gave even larger dimensions. It annually bears flowers and fruit; and though continuing thus to grow, does not appear much increased in size, in consequence of some of its branches being constantly blown down, as in the storm of July 1819, when it lost a great part of its top. The great size of this enormous vegetable is mentioned in many of the older authors; indeed as early as the time of Bethencourt, or in 1402, it is described as large and as hollow as it is now; whence, from the slowness of growth of Dracænas, has been referred the great antiquity of a tree which four centuries have so little changed. Humboldt indeed remarks that there can be no doubt of the *Dracaena* of Orotava being, with the Baobab (*Adansonia digitata*), one of the oldest inhabitants of our planet; and as tradition relates that it was revered by the Guanches, he considers it as singular that it should have been cultivated from the most distant ages in the Canaries, in Madeira, and Porto Santo, although it comes originally from India. This fact he adduces as contradicting the assertion of those who represent the Guanches as a race of men completely insulated from the other races of either Asia or Africa. To this it may be replied that we know too little of the botany of the interior of Africa to be able to draw from it any inferences; while the Dragon-Tree on the other hand is not known to exist farther to the eastward than the island of Socotra.—*Eng. Cyc.*

(3277) DRACOCEPHALUM ALTAIENSE. LABIATÆ. Many of these species are well known, amongst which is the D. Canariense, the balm of Gilead, with pretty blue flowers: the scent only lies in the leaves, and the plant seldom exceeds eighteen inches in height, the other species have large splendid blue flowers, and easily reared from seed; the plants are best grown in pots.—*Riddell.*

(3278) DRACONINA, a sub-family of Saurians belonging to the family Agamidæ, the tribe Strobilosaura, and the sub-order Pachyglossæ of Dr. J. E. Gray's arrangement.—*Eng. Cyc. Vol.* ii. *p.* 388.

(3279) DRACONTIUM POLYPHYLLUM. Lin. Wild carway Root.

Caat Carnaukalung, TAM	Adivie cunda gudda, TEL.
Junglie kunda ka gudda, DUK.	Kanana cunda, SANS.

This root after having undergone certain preparations, to subdue a little its acrimony, is supposed to possess anti-spasmodic qualities, and is considered as a valuable remedy in asthmatic affections, given to the quantity of twelve or fifteen grains in the course of the day. It is also one of the many remedies the Natives use in cases of Hemorrhois (Piles). In the dry condition in which we find it in the bazars, it has, though faint, a smell not unlike that of musk.—*Ains. Mat. Med. page* 73.

(3280) DRAGONS BLOOD.

Damulakhwain, ARAB.	Jaranang, PALEMB.
Indarume, DUK.	Khun-i-shavan, PERS.
Sangdragon, FR.	Catukamrigarakta, SANS.
Drachenbluth, GER.	Kandamoor-garittum, TAM.
Heeraduckkun, GUZ. HIND.	Catgamurgum, nitooru, TEL.
Sanguis Draconis, LAT.	

A dark-red, inodorous, insipid, resinous, colouring principle, mixed with benzoic acid, and other substances, and obtained from the surface of the ripe fruit of several species of palm indigenous to Hindustan, Cochin-China, and the Eastern Islands, especially Sumatra, at the towns of Jambi and Palembang, in which, and also in some parts of Borneo, this resin is chiefly procured. It is met with variously modified, sometimes in the form of drops or tears; of reeds or rods from 12 to 18 inches long, about the thickness of the finger, with the fronds of the palm wrapt round them; in masses or small pieces of a violet colour; while a spurious sort, composed of olibanum, turpentine, gum-senegal, &c. is not unfrequently substituted for the genuine article. Dragons Blood is employed as a colouring matter, as an ingredient in varnishes, and in the composition of tooth-powder: it is now seldom used as a medicine. It is imported into Bombay from Singapore, and is occasionally re-exported to England.—*Faulkner.* Dragons blood or Djamang,

is the produce of species of Calamus. Those which chiefly yield it are the *C. petmeus* (Lour.) *C. rudentum* (Lour.), *C. verus* (Lour.) and *C. draco* (Willd.), of which the last three were by Linnæus reckoned mere varieties of the *C. rotan* (Linn.) They are natives only of Hindustan, Cochin China, and the Moluccas. The ripe fruits are covered with a reddish-brown dry resinous substance, which is the Dragon's Blood. In this state they are collected, and allowed to remain in rice-mills till the resin drops off. The resin is afterwards melted, either by the natural warmth of the air or by artificial heat, and then moulded into the different forms in which it occurs in commerce. Another mode of obtaining it is as follows:—The ripe fruits are shaken in bags, and the resin so obtained is formed into pieces about the size of a bean, which are then wrapped up in leaves; this kind is much prized in the East Indies, A second sort is procured by throwing together the fruits after they have been treated in the foregoing manner, melting them in the sun or with a slow fire, and collecting what exudes, which is then formed into small four-cornered cakes. A third sort is obtained from what remains after the two foregoing processes, being run out and formed into round cakes, which contain hard portions of the fruit. According to other accounts, the finest sort is procured by exposing the fruits to the vapour of boiling water, and scraping off the soft resin as it exudes—*Eng. Cyc page* 713. Dragon blood, is the product of a palm, *Calamus Draco*, a native of Sumatra and the Malay Islands. The natural secretion of the fruit constitutes the best "*D'jurnang*," or Dragon's blood. A second and rather inferior kind is produced, by heat and bruising, the fruit, from which the natural secretion has been removed: the third, and most inferior, seems to be the refuse of the last process: it is perhaps doubtful whether it is ever procured from the plant by incisions. Large quantities of this drug are annually sent from Borneo to Singapore and Batavia, and thence to China, where it is much prized. In Europe, it is a constituent of some tooth-powders, and tinctures, and is also, and chiefly, used for colouring spirit and turpentine varnishes.—*Seeman*. This resinous gum has been long known; it received its present singular name from the ancient Greeks, who used it extensively. It is the concrete juice of the *Calamus rotang*, or rattan which grows wild in Borneo and Sumatra. It is found in the market either in oval drops, or in large and impure masses composed of several tears. That which is good is of a bright crimson when powdered, and if held up to the light in masses, is semi-transparent. The tears are usually the firmest, and the most resinous and pure. If it is black when made fine, or very friable in the lump, it is inferior. It is often adulterated with other gums; but that which is genuine melts readily and burns wholly away, scarcely soluble in water, but fluent in alcohol; while the simulated crackles instead of burning, and dissolves in water. Its uses are various in painting, medicine, varnishing, and other arts. The best is procured at Banjermassing Borneo, from whence it is carried to Singapore, and thence to the Chinese market in reeds, at $15 a $35 per pecul; the importation is principally in native vessels. The price in China varies from $80 to $100 a pecul after purifying and refining. The Chinese hold this gum in much estimation, and are the principal consumers of it in the East.—*Compendious Description*. This colouring substance is a granular matter adhering to the ripe fruit of a species of ratan, Calamus draco, and obtained by beating or thrashing the fruit in little baskets, Within the Archipelago, the principal place of production is Jambi on the north-eastern side of Sumatra. The plant is the wild produce of the forest, and not cultivated, although some care is taken to preserve it from destruction. The collectors of dragon's-blood are the wild people called Kubu, who dispose of it to the Malays, at a price not much exceeding a shilling a pound. The whole quantity produced in Jambi is said to be about 1000 hundredweights. The article is often adulterated by a mixture of damar. The best kind imported into Europe in reeds, is manipulated by the Chinese. The canes of the male plant used in former times to be exported to Batavia, and very probably formed the "true Jambees," commemorated in the Spectator as the most fashionable walking-sticks in the reign of Queen Anne.—*Crawfurd Dictionary, page* 123.

(3281) DRAGON CANE, is a kind of rattan, strong, springy and much valued. They occur both light and dark coloured: a variety with a soft bark is called Manilla Dragon Cane.—*Seeman*.

(3282) DRAPORE, a hard, fine, rather close-grained, somewhat heavy, Ceylon wood.

(3283) DRESSES, MUSLIN, WORKED. The Mahomedans of Madras are famed for the excellence of the flowered work on the Muslin dresses of ladies. They are sold at from Rs. 7 to Rs. 70 each.

(3284) DROGUE AMERE, a compound of mastic, frankincense, myrrh, aloes, and kreat.

(3285) DROSERA INDICA AND D. PELTATA. SUNDEW. In Tenasserim, there is frequently seen a delicate flower, so small that it is passed unnoticed by most observers, which is a species of drosera, that curious genus of the sundew tribe, which produces Venus' fly-trap. There are two different species at Tavoy.—*Mason*.

(3286) DRYOBALANOPS, a genus of Plants belonging to the natural order *Dipterace*æ, established by the younger Gærtner from specimens of the fruit found in the Banksian collection, supposed by him to belong to the tree which yielded the best cinnamon; but Mr. Colebrook,

from specimens sent to Dr. Roxburgh, which in the absence of the latter he received, ascertained that the fruit belonged to the Camphor-Tree of Sumatra, which he accordingly named *Dryobalanops camphora*, "until its identity with *D. aromatica* (of Gærtner) be established." ('Asiat. Researches,' xii.) Dr. Roxburgh had, in his manuscript 'Flora Indica,' already named it *Shorea camphorifera*. Some botanists are of opinion that the genus is not sufficiently distinguished from *Dipterocarpus*; but Blume, the latest author, and one who has had the fullest opportunity of examining the subject, has, in the article on *Dipterocarpeæ* in his 'Flora Javæ,' given it as his opinion that *Dryobalanops* should be kept distinct; as, like *Shorea*, it has all five instead of only two of its sepals prolonged into long foliaceous wings, while its cotyledons are unequal and rumpled. According to Blume the existence of this camphor-yielding tree was first indicated by Grimm in 'Ephem. Nat. Cur.' Kæmpfer was so well acquainted with its distinctness that in describing the Camphor-Tree of Japan (*Laurus camphora*) he says, "that natural camphor of crystal-like appearance, which is scarce and of great value, is furnished by a tree of Borneo and Sumatra, which is not of the Laurel genus." The first notice of the tree is in the 4th volume of the 'Asiatic Researches,' where we learn that a tree named Tappanooly on the west coast of Sumatra yielded about three pounds of camphor, and at the same time nearly two gallons of camphor-oil; that the tree resembles the bay in leaves, is fond of a rich red loam tending to a blackish clay, and that it grows principally on the north-west coast of Sumatra, from the Line to 3° N. lat. The fullest account is given by Mr. Prince, resident of Tappanooly, who describes the tree as growing spontaneously in the forests, and as being found in abundance from the back of Ayer Bongey as far north as Bacongan, a distance of 250 miles: he says that it may be classed among the tallest and largest trees that grow on this coast, several within daily view measuring 6 or 7 feet in diameter; but it will produce camphor when only 2½ feet in diameter. The same tree which yields the oil would produce camphor if unmolested, the oil being supposed to be the first state of the secretion, which ultimately changes into concrete camphor, as it occupies the same cavities in the trunk which the camphor afterwards fills; consequently it is found in young trees. The produce of camphor of a middling-sized tree is about eleven pounds, and of a large one double that quantity. ('Fl. Ind.' ii., p. 616.) This kind of camphor is very highly esteemed by the Chinese. It is commonly called Malay Camphor, or Camphor of Barus, from the port of Sumatra, whence it is mostly shipped. Its price in China is one hundred times greater than that of the common camphor of commerce.

(M'Culloch, 'Com. Dict.') In the same work it is mentioned that camphor-oil being nearly as cheap as spirits of turpentine, might perhaps be profitably imported into England as a substitute for the article, or for medicinal use. Camphor, which in many respects resembles the essential oils, has been shown by Dumas to be an oxide of hydrocarbon, indentical in composition with pure oil of turpentine; hence the term Camphene has been applied to it. But Dr. Thomson informs us that its camphor oil differs in some respects from camphene, as he was not able to produce camphor with the same facility or in equal quantity by driving a stream of oxygen gas through highly-rectified oil of turpentine, which Dumas regards as pure camphene.—*Eng. Cyc.* The *Dryobalanops camphora*, Colebrook; *D. aromatica*, Gaertner, is a large forest tree, and as far as is known, confined to a few parts of the islands of Sumatra and Borneo, but in these abundant. Its camphor is secreted in crystalline masses naturally, into cavities of the wood. It supplies this camphor only after attaining a considerable age. In its young state it yields, however, by incision, a pale yellow liquid, called the liquid camphor of Borneo and Sumatra, which consists of resin and a volatile oil having a camphorated odor. An account of this tree, and of the mode of procuring the peculiar and high-priced camphor which it yields, is given by Dr. Junghuhn, who has travelled lately in Sumatra, and Prof. De Vriese, of Leyden, in the "Nederlandsch Kruidkundig Archief" for 1851. An abstract of the memoir, translated into English by Miss De Vriese, is published in "Hooker's Journal of Botany" for February and March 1852:—The Dryobalanops is a gigantic tree, rising for fifty or even a hundred feet above those which compose the chief mass of the forests where they grow, just as the steeples of the churches appear above the roofs of the houses in a town. The trunks of the full-grown tree are from 7 to 10 feet in diameter at the very base, and from 5 to 8 feet higher up; they rise to the height of 100 or 130 feet, and their ample crown is from 50 to 70 feet in diameter. The tree has a limited range, being confined to the seaward slope of the mountains of south-western Sumatra, most abundant on the lower slopes and the outlying hills of the alluvial plain, and extending in latitude from 1 deg. 10m. to 2 deg. 20m. N., and perhaps further to the north. Camphor oil occurs in all the trees, and is most abundant in the younger branches and leaves. The solid camphor is found only on the trunks of older trees, especially in fissures of the wood, and in smaller quantity than is generally supposed. Colebrooke, and authors who have copied from him, assert that camphor is found in the heart of the tree in such a quantity as to fill a cavity of the thickness of a man's arm, and that a single tree yields about eleven pounds. The price of this camphor, which at

Padang sells for about 340 dollars per hundredweight, suffices to show that the account is much exaggerated. The camphor occurs only in small fissures, from which the natives, having felled the trees and split up the wood, scrape it off with small splinters or with their nails. From the oldest and richest trees they rarely collect more than two ounces. After a long stay in the woods, frequently of three months, during which they may fell a hundred trees, a party of thirty persons rarely bring away more than 15 or 20 pounds of solid camphor, worth from 200 to 250 dollars. The variety and price of this costly substance are enhanced by a custom which has immemorially prevailed among the Battas, of delaying the burial of every person who, during his life, had a claim to the title of Rajah (of which each village has one) until some rice, sown on the day of his death, has sprung up, grown and borne fruit. The corpse, till then kept above ground among the living, is now, with these ears of rice, committed to the earth, like the grain six months before, and thus the hope is emblematically expressed that, as a new life arises from the seed, so another life shall begin for man after his death. During this time the corpse is kept in the house, enclosed in a coffin made of the hollowed trunk of a Durion, and the whole space between the coffin and the body is filled with pounded camphor, for the purchase of which the family of the deceased Rajah frequently impoverish themselves. The camphor oil is collected by incisions at the base of the trunk, from which the clear balsamic juice is very slowly discharged. In Sumatra the best camphor is obtained in a district called Barus, and all good camphor bears that local name, being known in commerce as Brass Camphire, Borneo Camphor, Camphor of Baras, Malay Camphor. (Bruss-capoor, *Guz. Hind*.) It appears that the tree is cut down to obtain the gum and that not in one tenth of the trees is it found. Barus camphor is getting scarce, as the tree must be destroyed before it is ascertained whether it is productive or not. About 800 piculs are annually sent to China. The proportion between Malay and Chinese camphor is as eighteen to one; the former is more fragrant and not so pungent as the latter. Nine hundred and eighty-three tubs of camphor were exported from Java in 1843; 625 bales were imported in 1843, the produce of the Japanese empire, and 559 piculs exported from Canton in 1844. The price of unrefined camphor in the Liverpool market in July, 1853, was £4 to £4 10s, the cwt. There have been no imports there direct in the last two years.—*Simmonds*. Borneo camphor, as found in the wood of the Dryobalanops camphora, is in white crystalline fragments. Sp. G. 1·009. Its odour is not of so diffusable a nature, otherwise it closely resembles the camphor from the Camphora officinarum.—*Royle, page* 536. The wood of the camphor tree is good timber, suited for house and ship-building.—*Crawfurd's Dictionary, page* 81. The liquid camphor of the same tree appears of the nature of Camphogen. Dr. A. T. Thomson, by passing a current of oxygen gas through it, converted it into camphor.—*Royle*. The oil, both in a fluid and solid state, is found in the body of the tree where the sap should be, but not in all trees. The liquid oil is abundant, and little appreciated, but the concrete bears a very high price, which depends wholly on its scarcity and the fancy of the Chinese and Japanese, who ascribe high medicinal virtues to it which it probably possesses in no higher degree than the cheap article which they themselves obtain by the distillation of the wood of the Cinnamomum camphora, and which may be had in the same markets for about one hundredth part of the price. The Malay name is a slight corruption of the Sanscrit one, karpura. To distinguish it from the camphor of China and Japan, the wood Barus is annexed, being the name of the sea-port of the western coast of Sumatra, from which the article was principally exported from that island. From what Barbosa says, it is to be presumed that both the Malay and Chinese camphor were in use by the Hindus before the arrival of Europeans. The prices of the different sorts reduced to present Indian weights and moneys will be as they existed in Malabar and Calicut in the beginning of the sixteenth century, as follows: coarse camphor, in cakes (canfore grossa in pani), from 40 to 45 Spanish dollars, the picul of 133⅓ pounds, which is about double the present price at Singapore; camphor, to use internally, and for the eyes (canfora da mangiar, e per gl' occhi) 1360 dollars the picul, which is probably no more than 35 per cent. above existing prices in Singapore. There was also a sort used for anointing the idols (per ugner gl' idoli) at half the price of the last. These two must have been Malay camphor, while the first, from its low price, must have been Chinese or Japanese.—*Crawfurd Dictionary, page* 81.

(3287) DRY ROT, a well-known disease affecting timber, and particularly the oak employed for naval purposes. When dry rot is produced by the attacks of fungi, the first sign of it consists in the appearance of small white points, from which a filamentous substance radiates parallel with the surface of the timber. This is the first stage of growth of the spores of the fungus, and the filamentous matter is their thallus or spawn. As the thallus gathers strength it insinuates its filaments into any crevice of the wood, and they, being of excessive fineness, readily pass down and between the tubes from which the wood is organised, forcing them asunder, and completely destroying the cohesion of the tissue. When the thalli of many fungi interlace, the radiating appearance can no longer be remarked; but a

thick tough leathery white stratum is formed wherever there is room for its development, and from this a fresh supply of the destructive filamentous thallus is emitted with such constantly increasing rapidity and force, that the total ruin of timber speedily ensues where circumstances are favourable for the growth of the fungi. It is generally stated that dry rot consists of the thallus of *Merulius lacrymans*, or *Polyporus destructor*, two highly-organised fungi, whose fructification is sometimes found upon rotten timber. But it is a great mistake to suppose that dry rot belongs exclusively to those two species, or that they are even the common origin of it: on the contrary, there is reason to believe that any of the fungi that are commonly found upon decaying trees in woods are capable of producing dry rot, and it is quite certain that one of the most rapidly-spreading and dangerous kinds is caused by the ravages of different species of *Sporotrichum*. The latter throw up from their thallus whole forests of microscopic branches loaded with reproductive spores, of such excessive smallness that they may insinuate themselves into the most minute crevices or flaws even in the sides of the tubes of which timber consists, and they are infinitely more dangerous than *Merulii* or *Polypori*, which seldom fructify. The circumstances that are most favourable to the development of the dry rot fungi are damp, unventilated situations, and a subacid state of the wood. The latter condition, especially in oak, is easily produced by a slight fermentation of the sap which remains in the timber, especially if the latter has not been well-seasoned before being employed. It has been proved experimentally that fluids which, in their ordinary state, will not produce fungi, generate them abundantly if ever so slightly acidulated. Dutrochet found that distilled water holding in solution a small quantity of white of egg will not generate fungi in a twelvemonth, but upon the addition of the minutest quantity of nitric, sulphuric, muriatic, phosphoric, oxalic, or acetic acid, it generated them in eight days' time in abundance. Alkalescent infusions possess the same property. This observer states that the only poisons which will prevent the appearance of fungi are the oxides or salts of mercury. A solution of fish-glue yields fungi rapidly and in great abundance; but a small quantity of red precipitate or corrosive sublimate destroys this power entirely. It is moreover an important fact that no other mineral preparation has any such properties. Dutrochet ascertained that other metallic oxides acted differently. Oxides of lead and tin hastened the development of fungi; those of iron, antimony, and zinc, were inert; and oxides of copper, nickel, and cobalt, although they retarded the appearance of fungi, yet did not prevent their growth in the end. These facts are confirmed by the experience of the use of Kyan's process for preparing timber, which consists in submitting the wood to the action of corrosive sublimate. Immersing the wood in chloride of zinc also prevents the attack of fungi, and also submitting it to the action of the vapour of creasote. Dry rot also occurs in animals. Specimens of hymenopterous insects resembling wasps have been brought from the West Indies with a fungus allied to *Sphæria militaris* growing from between their anterior coxæ, and it is positively asserted by travellers that the insects fly about while burdened with the plant. Upon opening the bodies of the wasps they are found filled with the thallus of the fungus up to the orbits of the eyes and the points of the tarsi: the whole of the intestines being obliterated. In such cases it is to be supposed that the thallus of the Sphœria first kills the wasp by compressing and drying up the body, and then, continuing to grow, occupies the whole of the cavity of the shell of the insect. A more common instance of animal dry rot is the disease in silkworms called La Muscadine. Silkworms of all ages are occasionally liable to become sickly and to die, soon after death becoming stiff, and acquiring such a degree of firmness as to be readily broken. They then throw out from their surface a sort of white efflorescence, which is the fructification of the fungus called *Botrytis Bassiana*, their inside being filled by the thallus of the same plant. If some healthy caterpillars are placed beneath a bell-glass, along with a small portion of worm killed by the *Botrytis*, they soon catch the disease, exhibit the same symptoms as those already mentioned, and eventually perish; having, no doubt, been infected either by rubbing themselves against the dead worm, or, which is more probable, having received upon their skins the infinitely minute seeds dispersed by the *Botrytis*. If healthy crysalids are inoculated by the introduction below their shell of a little of the *Botrytis* matter upon the point of a needle, they also sicken and die. In these cases effects are produced upon insects similar to those upon timber; that is to say, vitality in the one case and cohesion in the other is destroyed by the growth of the thallus of certain fungi, which spread with great and irresistible rapidity, and fructify where occasion offers.—*Eng. Cyc.*

(3288) DRYANDRA CORDATA of Thunberg, the tung-eu of the Chinese, is valuable on account of the quantity of oil found in its seeds, and the tallow-tree, Stillingia sebifera, which furnishes both tallow and oil. Here and there were plantations of the common Chinese pine, and the lance-leaved one known to botanists as *Cunninghamia lanceolata.*—*Fortune's Tea Districts, page* 57. The tallow-tree (*Stillingia sebifera*) and the "Tung-eu" (*Dryandra cordata*, Thunberg) both produce articles of export. The former is well known to produce the tallow and oil so

much in use in China: the latter furnishes a valuable oil which is used in mixing with the celebrated varnish of the country, and hence this tree is often called the varnish-tree.—*Fortune's Tea Districts, page* 119. Dryandra cordata, or wu-tung of the family Proteaceæ, is one of the favourite trees of the Chinese, for its beauty, the hard wood it furnishes, and the oil extracted from its seeds.—*William's Middle Kingdom, p.* 281.

(3289) DUBBER.

Dubber, or Dupper, Guz. Hind. | Sidde, Tel.

Are vessels of various capacities, generally from 5 to 15 gallons, formed of thin untanned goat-skin. They are manufactured in many parts of India, where they are employed to contain chiefly oils and ghee.—*Faulkner.* Dubbers are bottles formed of skins, and used for holding and conveying spirits, oil, ghee &c. They are made of all sizes, from a quart to 10 or 20 gallons, they are formed of untanned goat skins by stretching them when wet over unburned hollow clay-forms, the edges being well rubbed down on the lower skin to cause adhesion. The clay core is readily removed after the bottle is dried in the sun.—*Rohde M.S.S.*

(3290) DUGONG, Malay. The Dugong is an inhabitant of the narrow seas of the Eastern Archipelago. Professor Owen has denominated the Dugong of the archipelago, *Halicore indicus*, in distinction from that of the northern coast of Australia, at a time when the former had not been ascertained to frequent (as a Dugong of some kind is now known to do) the Malabar coast and Gulf of Calpentyn in Ceylon; but it still remains to be proved that this is the true Malayan Dugong, however little reason there may seem to doubt it,—as there might equally have seemed little cause to suspect the distinctness of the *Halicore australis!*

(3291) DUKU. The Malay and Javanese name of a tree and fruit of the genus Lansium, and natural order Meliaceæ of botanists. To the same genus belong the langseh, langsat or langsab, for in all these forms the word is written, the rambeh and the ayar-ayar, probably all four but varieties of the same species. The duku is the most esteemed of them, and to the European palate is the best of the native fruits of the Archipelago, after the mangostin. The natives class it after the durian and mangostin. It is of the size of a pigeon's egg, of globular form, and covered with a coriaceous skin of the colour of parchment. The species seems to be indigenous in the western portion of the Archipelago, but to have been introduced into the Philippines, where one variety of it, the langseh, is cultivated.—*Crawfurd Dict. page* 125.

(3292) DULCAMARA. The Dulcamara contains an active narcotic alkali, Solanine. This preparation is narcotic and diuretic: dose dr. ½ to oz. 1, thrice daily. It is very desirable to ascertain whether the Indian species, solanum nigrum, Arrub-ul-saleb, possesses similar virtues. (See Dispensatory, p. 462.)—*Beng. Phar. p.* 277.

(3293) DUMREE, a small copper coin (formerly) current in the Carnatic; now rarely seen.

(4294) DUNGAREE.

Dungaree, Guz. & Hind. | Datta, Tam.
Dungaree, Tel.

The Indian name of a coarse cotton fabric, manufactured in various parts of India, and used by the poorer classes of natives. The stouter kinds are much employed in the making of sails for native sailing vessels. On the Malabar Coast, and in Guzerat, dungaree is largely manufactured.—*Faulkner.* Dungaree is a kind of cloth woven with two or more threads together in the web and woof; it is generally used for sails of country ships, and would no doubt be advantageously employed for the occasional light sails for larger ships, being more easily handled than European canvas. Superior descriptions are made with the web and woof, or web only, twisted either wet or dry, but this becomes as expensive as the best English canvas: the present price of the ordinary dungarees, 30 cubits, that is 15 yards long and 2 feet wide, is 1 rupee 12 annas the piece at Masulipatam, being brought from Raylungy, a village and Talook to the northward, where a finer description, well adapted for tents, is made at 7 Rupees the piece of [illegible] yards, 1 yard wide. About Vizagapatam the ordinary Dungaree is usually sold by weight. The best Bengal tents appear to be made of an open textured dungaree, the threads of which are finer than is usual in dungarees. Like all other cotton goods, dungaree should not be exposed to the weather in sails, tents &c., till the weavers dressing and filth has been thoroughly removed by washing and partial bleaching.—*Rohde M.S.S.*

(3295) DUNGING OF CLOTHS, is a process resorted to by dyers both in this country and Europe, the object being to impregnate cotton cloths with animal matter for which many dyes have a strong affinity.—*Rhode M.S.S.*

(3296) DURANTA ELLISIA. Verbenaceæ. This is a beautiful large shrub with light blue pendulous flowers, it blossoms almost throughout the year, readily grown from cuttings, the flowers are scentless.—*Riddell.*

(3297) DURANTA PLUMIERI.—This is a large shrub like the former, with handsome drooping blue flowers having the scent of almonds: the clusters of seed berries which are numerous, when ripe, have a very pretty appearance from their dark orange colour, they do not appear to germinate readily.—*Riddell.*

(3298) DURIO, a genus of Plants of which the name has been derived from Durion, a well-known fruit of the Malayan Archipelago. The

specific name of *Zibethinus* has been applied to the tree which forms this genus, from the fondness of the Malayan Zibet (*Viverra Rasse*, Hors.) for this fruit. The genus *Durio* belongs to the natural family of *Bombaceæ*, considered by some botanists to be only a tribe of *Sterculiaceæ*. It is characterized by having its five petals smaller than the five lobes of the calyx. The stamens, long and numerous, are arranged in five bundles, and have twisted anthers; the free germen is surmounted by a long filiform style and capitate stigma; the fruit, roundish and muricated, is divided internally into five cells, and easily separates when ripe into five parts; each cell contains from two to four or five seeds enveloped in soft pulp.—*Eng. Cyc.*

(3299) DURIO ZIBETHINUS is a large and lofty tree, with alternate leaves, which are small in proportion to its size; in form they resemble those of the cherry, or are oblong-pointed, small and green above, like nutmeg-tree leaves, but on the under surface are covered with orbicular reddish-coloured scales, as some species of *Capparis*; the petioles are tumid, and furnished with a pit towards their base; the flowers are arranged in clusters on the trunk and older branches, where of course is also borne the fruit, as in the Jack and Cocoa trees. The Durion is a favourite food of the natives during the time (May and June) when it is in season; but there is usually also a second crop in November. It is as remarkable for the delicacy combined with richness of its flavour, as for the intolerable offensiveness of its odour, which is compared by Rumph to that of onions in a state of putrefaction, on which account it is seldom relished by strangers, though highly esteemed by many European residents. In size it is equal to a melon, or a man's head, and sometimes compared to a rolled-up hedgehog (hence it has been called *Echinus arboreus*) in consequence of its hard and thick rind, which is yellow-coloured when ripe, being covered with firm and angular projections. From this appearance has likewise been derived its Malayan name, 'dury', in that language signifying a thorn or prickle. (Rumph.) The seed, with its edible enveloping pulp, is about the size of a hen's egg; the latter is as white as milk, and as delicate in taste as the finest cream, and should be eaten fresh, as it soon becomes discoloured, and undergoes decomposition. Excessive indulgence in this, as in other fruits, is apt to create sickness, and therefore to its abundance has been sometimes ascribed the unhealthiness of some years; but as the crop of fruit is most abundant when the rains are very heavy and follow great heats, the sickness is probably due as much to the peculiarities of the season as to the too free use of this fruit. The seeds of the Durion are likewise eaten when roasted, and have something of the flavour of chestnuts. The wood of the tree is valued for many economical purposes, especially when protected from moisture. The rind of this fruit is likewise turned to account by the industrious Chinese, as its ashes, when burnt, probably from containing potash, are used by them in the preparation of some dyes. Marsden, in his account of Sumatra, quotes a celebrated writer as saying that "Nature seems to have taken a pleasure in assembling in the Malay Islands her most favourite productions." Among these may be enumerated the Mangosteen, the Jack and Bread-Fruit trees, the Lanseh, and Durion, with others which are common in other tropical parts. These, it has not been possible to cultivate in the hothouses of England, even with all the skill of its horticulturists; a circumstance which must be ascribed partly to the great size of the trees, and partly to the peculiarity in climate of 'India aquosa,' as this part of the world was called by old writers. But as it is only within a few years that moisture has been combined with heat in the present successful cultivation of Orchideous Plants, it might perhaps be possible to make some of the above fruits grow in a similar artificial climate; and, by grafting, to make them bear when only a few feet high, as has been done with the Mango in India.—*Eng. Cyc.* The dorian holds an important place among the fruits of Tenasserim, being regarded by the voluptuous natives as second to none. It is probably the most fœtid fruit in existence. Wight speaks of "the dorian so celebrated on account of its fine flavored but excessively fœtid fruit;" and adds: "it is said by Rumphius to be of a very heating quality, liable to excite inflammatory derangements of the system."—*Mason.* The *Durio zibethinus*, or Dorian fruit (Doowin, *Burm.*) can scarcely be said to belong to Pegu, although there are a few trees about Rangoon, which bear fruit, yet the King of Burmah has always obtained the supplies for the royal table from Moulmein.—*McClelland.* The tree has lately been introduced into the Company's gardens on the Madras side. According to Crawfurd, the Durio zibethinus of botanists, is the only plant of the genus. This famed fruit is about the size and form of a large melon, and contains esculent seeds resembling chestnuts, which are enveloped in a large quantity of a pale yellow pulp, which is the esteemed part of the fruit. This is of the consistence of clotted cream, and has the taste of fresh cream and filberts. Although possessing an offensive odour, resembling that of over-ripe apples, so powerful and diffusive as to taint the air of a whole town when it is in season, the pulp is rich without being cloying. The natives of the countries yielding the durian, prize it beyond all other fruits. In countries with a suitable climate, it flourishes without care or culture. It is most abundant in the western portion of the Archipelago, and extends east as far as the island of Mindano, the only one of the Philippine group in which it is

known. It is abundant in Siam, however, up to the 13th and 14th degrees of north latitude; and again it is found on the coast of Tenasserim, in about the 14th degree of latitude, which is the furthest distance from the equator to which it has been successfully propagated. All attempts to cultivate it in any part of Hindustan have failed; nor has it, like some other Asiatic fruits, been transferred to tropical America. Crawfurd did not find that it was grown in Cochin-China, although he thinks it most likely that it is so in some parts of Kamboja. A hot, moist, and equable climate would seem to be indispensable to the durian, but soil seems to be indifferent to it, for it thrives in the granitic, in the sandstone, and in the calcareous ones of the Peninsula and Sumatra, in the volcanic soil of Java, and in the rich alluvium of the valley of the Menam in Siam. The name, which is perhaps most correctly written durian, is pure Malay, and is a derivative from the word duri, a thorn or prickle, in reference to the sharp tubercles with which the rind is covered. This name, with trifling variations, is that of the fruit in every country in which it is found from Java to Siam, and it has no other. From this, therefore, I think it may be inferred that the tree is a native of the country of the Malays, viz., Sumatra, the Peninsula, and their adjacent islands, and that through the Malays it was more widely disseminated. It may even be stated to grow wild in some, at least, of the countries named. An intelligent writer in the Journal of the Indian Archipelago thus incidentally refers to the subject, in a paper rendering an account of the wild inhabitants of the interior of the Malay peninsula. "In several places in the interior of the forest are found durian trees, always in a body together, to the number of about ten or twelve trees. Such places are for the Jakuns an object of great attention, and matter of work. They cut with the great axe all the other trees which surround the durians, that these, by receiving more air, may grow up more easily, and give finer, and a greater quantity of fruit. They build there a small house, of which I will hereafter speak; and they then return to their ordinary habitations, which are sometimes distant from such places one or two day's journey." Another writer in the same publication, writes to the same effect respecting the durian, as it is seen to grow spontaneously in one of the small islands off the eastern coast of the peninsula, and which is nearly one entire forest down to the margin of the sea. "At Pulo tingi," says he, "we found orang-lant, or sea-gypsies, assembled. A large crop of durians this season, had attracted tribes of them from the coasts of the peninsula, as well as from the islands of the Jehore Archipelago. Six boats from Moro, an island of that group, we found on their way to Pulo tingi; they had travelled by sea a distance of 180 miles, to partake of the fascinating fruit.—*Crawfurd Dictionary page* 126.

(3300) DUTCH RUSH, Horse Tail. A hollow-stemmed, leafless plant (*Equisetum hyemale*); with a cuticle composed of pure silex, which gives it a hard surface that makes it useful for polishing wood and metals, a purpose to which it is extensively employed in England. It is generally obtained from Holland.—*Waterston. Faulkner.*

(3301) DYSOPHYLLA QUADRIFOLIA. *Mentha quadrifolia. Wild Mint.* There is a species of wild mint in Tavoy, of which Roxburgh wrote: "This plant is very fragrant, not less so than our garden mint in Europe."—*Mason.*

(3302) DYES, DYEING, and COLOURING STUFFS.—Dyeing is the art of imparting to wool, silk, cotton, linen, leather, &c., colours which resist the operation of washing and the wear to which they are subject when made up into articles of furniture or clothing. This art was known at a very early period. Jacob made for Joseph a coat of many colours, (Gen. xxxvii. 3;) and in Exodus frequent mention is made of the ornaments for the Tabernacle as being composed of blue, purple, scarlet, and fine linen. We read also in 2 Chron. ii. that Solomon having sent to Tyre for coloured linens, the king of that country answered his request by sending him a man skilful to work "in purple, in blue, and in fine linen, and in crimson." Ezekiel, (593 B.C.) in his prophecy against Tyre (xxvii. 7), speaks of "blue and purple from the isles of *Elishah*," which has been supposed to refer to Elis on the west side of the Greek Peloponnesus, and hence it has been inferred that the Tyrians in the time of Ezekiel drew their supply of shell-fish used for dyeing purple from the coast of Greece. The Tyrian purple was greatly prized among the nations of antiquity. It is supposed to have been obtained from two different kinds of shell-fish, described by Pliny under the names *purpura* and *buccinum*; it was extracted from a small vessel or sac in their throats, one drop only being obtained from each animal, but an inferior colour was obtained by crushing the whole substance of the buccinum. A quantity of the juice having been collected, sea salt was added, and it was allowed to stand three days; after this, it was diluted with five times its bulk of water, kept at a moderate heat for six days more, and occasionally skimmed, and when thus clarified it was used for dyeing white wool previously prepared by the action of lime-water or of a species of lichen. For the finest Tyrian purple, the wool was first plunged into the juice of the purpura, and then into that of the buccinum; by exposure to air and light the wool passed through various shades of citron yellow, green, azure, and red, and after 48 hours a

fine purple was produced. In some cases the wool was first dyed with a cheap dye, and the woven cloth was finished with the precious juice. The colours were durable, but very costly: Pliny states that a pound weight of the double dipped Tyrian purple was sold in Rome in the time of Augustus for 100 crowns, (equal to about 30*l.* of our money.) This enormous price did not prevent many of the citizens of Rome from wearing purple attire until the time of the emperors, when the use of purple was limited to them. This exclusiveness proved fatal to the manufacture: it languished until the eleventh century, and then became extinct. In the seventeenth century the art of dyeing purple was revived by Mr. Cole, of Bristol, and in the eighteenth century by M. Reaumur, of France; but by this time finer colours had been discovered, and cheaper processes invented. The ancient Greeks do not seem to have attended much to the art of dyeing: the people of Athens wore woollen garments of the natural colour, and although the more luxurious Romans patronised those who cultivated the art, yet the processes of a trade or manufacture were thought to be beneath the notice of any writer capable of describing them. We learn incidentally from Pliny that the competitors in the circus were clothed in dresses of green, orange, grey, and white. The art was lost at Rome after the invasion of the northern barbarians in the fifth century; but it was practised in the East and revived in Europe about the end of the twelfth century. Florence became celebrated in the art, and in the early part of the fourteenth century numbered not less than 200 dyeing establishments. The discovery of America supplied Europe with a variety of new colouring-matters, such as indigo, logwood, quercitron, Brazil-wood, cochineal, arnotto, &c. Before the introduction of indigo, woad was used for dyeing blue, and the cultivators of this plant in England and on the Continent endeavoured to prevent the use of indigo, which, by a decree of the German Diet in 1577, was declared to be "a pernicious, deceitful, eating, and corrosive dye." The introduction of logwood was opposed from similarly interested motives: its use was prohibited by a statute of Elizabeth, under heavy penalties, and all that which was found in the country was ordered to be destroyed: it was not until the reign of Charles II. that its use was permitted. Such narrow prejudices as these of course interfered with the progress of the art in this country; but by degrees, valuable improvements were made, and new processes introduced from abroad, such as the method of dyeing Turkey-red,—one of the most durable of colours. It was discovered in India, and afterwards practised in other parts of Asia and in Greece. About the middle of the last century some Greek dyers established dye-works for this colour in France; and in 1765 an account of the method of producing it was published, by order of the French government. About the end of the last century the method was practised in England, when a Turkey-red dye-house was established in Manchester, by a Frenchman, who obtained a grant from Government for the disclosure of his process, which however, was not very successful. A better process was introduced into Glasgow by a Frenchman named Papilon; but before this, Mr. Wilson of Ainsworth, near Manchester, had obtained the secret from the Greeks of Smyrna, which he made public. The methods of imparting a permanent colour to textile fabrics are almost as numerous as the colouring matters employed. Most of the colours used in dyeing are vegetable: a few are animal and mineral. The most vivid and brilliant vegetable colours, such as those of flowers and other parts of plants exposed to the light, are small in quantity, very fugitive, and difficult to separate. The colouring matters of plants capable of being isolated, are mostly yellow, brown, and red; the only blue dyes furnished by plants are indigo and litmus; no black vegetable dye has been isolated. Most vegetable colours are soluble in water; and those which are not so can be dissolved in alcohol, ether, or the fixed oils. Vegetable colours are permanent in dry air; but they gradually fade in moist air, especially under the influence of light. The blue of most flowers is converted into red by an acid, and into green by an alkali. Not only do the methods of dyeing vary with the nature of the dye-stuff, but also with that of the material to be dyed; different methods being adopted for cotton, silk, and wool.—*Tomlinson, page* 527. In Southern Asia, the art of dyeing is no doubt of very ancient date, and one with which the Hindoos and Chinese have long been well acquainted. Their country furnished all the raw materials for producing a great variety of colours; some of these are of so conspicuous a nature, such as the large flowers of plants, that the desire must early have occurred to transfer these colours to the person in savage nations, or to the clothes of so early civilized a people as the Hindoos. This could easily have been done with the fugitive colours, but as they know how to make a colour like that of indigo, which undergoes a considerable degree of chemical change during its formation as well as while applied to the dyeing of its blue colour, it is evident, even if we had no other information on the subject, that they must have paid attention to some chemical subjects. But we know that they have long possessed, and knew how to manufacture, the several salts which have long been employed as mordaunts. That the art of dyeing was early practised we have the proof in the fact mentioned by Pliny, that flags of various colours were displayed by the Indians. It has been supposed that the Hin-

doos may have learned this art from the Egyptians, but the probability is as great that the latter learned the art from the former, from whom also they probably obtained the alum which was celebrated by the name of Egyptian alum. Alum is still manufactured in Cutch; the natives of India have long known the use of sulphate of iron and of acetate of iron. The latter they prepare by macerating iron in sour palm-wine, or in water in which rice has been boiled. The alkalis and acids with which they are acquainted may have assisted them in changing the shades of colours, many of the details of the dyeing processes, are well known, and seem to have been the original of many of those followed in Europe until very recent times. The Exhibition of 1851 has shown the people of Europe that they can dye every colour, and of a great variety of shades, and that, in a complicated pattern, they know the value and power of each in contrasting the effect of others, so as to produce an harmonious whole.—*Royle, Arts &c. of India page* 481. Though the methods of dyeing practised in India are generally tedious and complicated, the natives have long possessed the Art of giving beautiful and permanent colours to cotton goods. The country supplies all the raw materials for producing a variety of colours, and the Hindoos have long been acquainted with Alum and the salts of Iron. &c. which are still employed as mordants. But in a country where chemical science may be said to be unknown, we naturally cannot look for any of those signs of progress, which in Europe, have marked the application of that science to the art of dyeing. The process is as rude as it was ages ago, and any improvement in colour, or production of a new one, has been rather the result of a happy accident, or an elaborate painstaking experiment, than a skilful combination upon understood principles. Yet the field is one that well merits labour and research, for, whatever be the external influence that operates in this country, the colours produced in dyeing are unquestionably brilliant, and the best test of their superiority is understood to have been afforded some years past, when Manchester cloths were sent out to the country to be dyed, and returned home to enter the market as the "Blue cloths of Commerce." It is almost entirely cloth of Cotton that the natives of Southern India treat, and they are able to impart durable colours to this in reds, blacks and blues, and the various modifications of these; but their deep greens, yellows and other colours appear to be very fugitive. Dr. Heyne has published an accurate account of the mode of dyeing cotton yarn, as practised on this Coast, in his Tracts, (P. 204,) and below is a statement furnished by a Native working dyer at Madras, of the manipulation and materials employed by him for producing various colours. It is very evident from these documents, that the Native dyers have at this

day much to learn, and that their processes may be very materially improved. From the great diversity of substances used in dyeing, including metals, woods, flowers, roots, barks, leaves, fruits, lichens, insects, &c., all of which require essentially different treatment; there is considerable variation in the methods practised, —and this variety is further increased by the different nature of the materials submitted to the dyes, *viz.*, *Animal substances*, Wool, Silk and leather; *or Vegetable materials*, as Cotton, flax and wood. Experience shows that the colouring matter, which takes upon animal substances, will not suit vegetable matter, a piece of wool will bear an acid, which would corrode and destroy a cotton fabric, and the dyeing of mixed fabrics, where animal and vegetable matters are combined, and where several brilliant colours are blended together, requires the manufacturer to practise all the nicety of his Art. Dyeing is indeed a purely *Chemical* process, and it is owing to the progress of that *Science* in Europe, that such great improvement has been made of late years, and that many colouring matters, which were formerly considered of but little value, are now rising in importance, (such as Munjeet, Chayroot, Logwood, Annotto,) and being more extensively brought into use, with a few little known substances as Puply Chuckay, Ratinara, (Lichen), and extract of Casuarina, &c. Amongst some of these little known dyes, there are several well deserving a careful examination. It is to be hoped, that some method may be devised of rendering them available, as well as of applying more economically, those long in use, and which may be procured in large quantities and at low prices.—*M. E. J. R.* The following lists comprise the principal part of the colouring materials of Southern Asia.

Redwood,	Adenanthera pavonina.
Barberry Wood and Root, (Berberis Lycium, Aristata, &c.)	
Black Vegetable Dye, of,	Nepal and Burmah, Shan..
Annotto,	Bixa orellana.
Pulas flowers,	Butea frondosa.
Safflower (kusoombha,)	Carthamus tinctorius.
Beef Wood,	Casuarina.
Sappanwood (bookum, putung,).	Cæsalpinia sappan.
Chirunge (red dye,)	Chirongia sapida.
Chulchuliera, Lichen, of	Himalayas.
Lichen, of	Scinde.
Turmeric. (huldee,)	Curcuma longa.
Logwood	Hæmatoxylon campechianum.
Indigo,	Indigofera tinctoria.
Malapoo (dye,)	
Aliakoo,	Memecylon tinctorium.
Aal (aal, ach,)	Morinda citrifolia.
Chay root,	Oldenlandia umbellata.
Red saunders,	Pterocarpus santalinus.
Turkey Berries,	(Rhamnus Sp.)
Capala-rung,	Rottlera tinctoria.
Madder, Indian (munjeeth,)	Rubia munjistha.
Roum v. Room, a blue dye, (Ruellia Sp.,)	Assam. China.
Lodh,	(Symplocos racemosa,) Himala-
Myrobolans (hur and behara,)	Terminalia Sp. [yas.
Papli chuckay (orange dye,)	Ventilago (?)
Palay Indigo,	Wrightia tinctoria.—*M.E.*

Other plants are used as dyes, as the flower of the Nyctanthes, and Toon. Also Pomegranate rind, Marking Nut, and Acacia bark.—*Royle, Pr. Res.* Though, as mentioned above, the methods of

dyeing in use in India are generally very tedious and complicated, yet they have long possessed the art of giving beautiful and permanent colors to cotton goods. Dr. Heyne suggested the advantage that might accrue to European dyers from a knowledge of their methods, and the process by which the beautiful Turkey red dyes are at present, owing to a late invention, given to cotton goods in Europe, very much resembles in many of its features the process of dyeing yarn red practised on the Coromandel coast, with substitution of madder for chay root. Mr. Rohde does not think that any durable colours are communicated by natives to cotton cloth, except reds and blacks and modifications of the one or the other, their deep blues, yellows and other colours seem very fugitive. Their dye stuffs consist chiefly of alum, anatto, Bole armenian, Capalapodie (the dust shaken from the root of the dry fruit of the Rottleria tinctoria, a product of Malabar) Indigo, the prepared, and also the wild weed, cassia leaves, seeds of the oval leaved cassia, Catechu, chay-root, Galls, Iron rust, karam, (anim, pure carbonate of soda or alkaline earth) Lime, Limes, Lowd or Loder bark, Madder or Munjeet of Bengal, the bark of the Marudum, of the many flowered Phyllanthus, milk hedge, Morinda, Mirobolan chebulic, flowers of the Nyctanthes arbortristis, of the Butea (Poorsha) frondosa; of the sering; of the shoe flower, (sa-pa-ri) red and yellow ochre, gingilie oil, over munnoo, (Natron) the blue dyeing Rose-bay (Nerium tinctorium) saffower, sal ammoniac, Sappan wood, Tamarind leaves and fruit, Teena flowers, Turmeric; Ver digris, Red wood, Asclepias gigantea, milk hedge sap: Vattany cuttay (Pattengi chucka,). Impure carbonate of Potass, Plantain skins, Poonhuran, an alkaline earth, Pappilia, *Tam.*—The process of dyeing cloth practised by Bala Chetty at Madras is as follows:

Red Colour.—Dissolve small quantities of ashes, procured by burning the milk hedge tree, in water, filter and add an equal quantity of sheep's droppings and Gingelcy oil to the solution. Soak the yarn in the mixture twice a day for 20 days, drying the yarn in the sun during the intervals. Wash the yarn white in pure water and dry. Steep it in a mixture of chay root powder, and causa leaf, coarsely powdered, for three successive days, both morning and evening, drying the yarn during the day; steep the yarn again for 5 days (morning and evening) in a mixture of chayroot powder and drying it for 5 successive days, and on the 6th night, boil the yarn in a closely covered vessel for 12 hours, and wash it in pure water, on the following morning, when a fast red colour will be found.

Purple.—If the yarns dyed by the above process be steeped for some time in a solution of Indigo, a deep purple colour will be produced.

Light Purple.—If white yarn prepared as above detailed, be soaked for 5 successive days, both morning and evening, in a solution of *Soorool Puttay*, dry the yarn in the sun and boil it as prescribed for the red colour, a shade of purple colour will be produced.

Shade of Purple Red.—If the yarn prepared, as for the light purple, be soaked in a solution of Puplichuckay powder, a different shade is produced.

Blue Black.—Indigo. If a mixture made of powdered chunam and extract of Thakaravaray (cassia auriculata) be put into an earthen vessel, partly burnt in the earth and the yarn steeped in it for 8 days, will produce different shades of black. The mixture must be constantly stirred during the process of dyeing.

Sky Blue.—When a light preparation of the mixture, above prescribed is made and the yarn soaked in it 3 times a day, will produce the sky blue colour.

Black.—If white yarn be soaked in a paste made of Kadukay powder (Terminalia chebula) and green vitriol and again steeped in a bath of tank mud, the yarn will have various shades of black colour—and this will depend upon the intensity of the dye used.

Pink or Rose Colour.—If powdered Coosumba flower (carthamus tinctorius) be well washed with water and mixed with Applacarum—it is then to be trodden under feet, strain and add lime juice to it—bleached yarn to be soaked in this mixture and a beautiful rose colour will be produced.

Orange Colour.—Mix Turmeric powder in water, soak the bleached yarn in this mixture, and dry, soak the yarn again in the Coosumba mixture and an orange colour will be produced.

Yellow Colour.—Mix a quantity of Turmeric powder in water, soak the yarn for 24 hours, squeeze and let it dry, repeat the operation for 4 successive days, then soak the yarn again in a solution of Turmeric powder with Alum, morning and evening, squeeze the yarn and let it dry, when a bright yellow colour will be produced.

Straw Colour.—Soak the yarn in a solution of Turmeric powder and water, 4 or 5 times, squeeze and steep the yarn again in a solution of lime juice and fresh water for about an hour—squeeze it well, and dry, when a straw colour will be produced.

Green Colour.—Soak the bleached yarn in a solution of Indigo, dry and then steep it in a solution of Turmeric powder and water for 48 hours, wash the yarn in a mixture of lime juice and water and dry it in the shade when a green colour will be produced.

Orange Colour.—Tie a quantity of Annato seeds in a piece of cloth, soak it in water for 12 hours, squeeze the colouring matter out in a basin of fresh water, add cocoanut water, lime juice

and alum powder, steep the yarn in the mixture for 4 hours and then boil it for an hour—squeeze and let it dry, when a deep orange colour will be produced.

Bleaching silk.—Steep the silk in a solution of chunam and Dhobys' earth for 24 hours, wash the yarn in fine water and then soak it in Alum for an hour (which is a mordant) and again for 2 hours in a mixture of soap and Indigo, when the yarn will be bleached to a white colour; wash and let it dry.

Red Colour.—Tie a quantity of stick lac, coarsely powdered, in a strong cloth and macerate it in warm water, bruising it occasionally with a wooden hammer, till it ceases to yield any colouring matter: add to the liquor a small quantity of Tamarind pulp and Alum powder, boil the silk in this mixture for 2 hours, and wash, when a deep red colour will be produced.

Crimson Colour.—Make a mixture of Chironjee seeds, Buchanania latifolia, add a small quantity of Alum and boil the silk (which has been previously bleached and dyed deep red) for an hour, squeeze and dry, when a crimson colour will be produced.

Orange Colour.—Make a mixture of Fuller's Earth and Cupla powder, add a small quantity of Alum and boil the silk (which has been previously bleached and dyed red) for 2 hours, when cold, squeeze and dry, when an orange colour will be produced.—*M. E. J. R.*

Coloring substances for staining and dyeing are obtained indifferently from the animal, mineral, and vegetable kingdoms; and the importance of a careful consideration of this subject will be admitted, if we consider how much the prosperity and extent of the cotton, silk, woollen, and leather manufactures depends on a liberal and cheap supply of dyes and tannin, to give beauty and color to the fabrics, and substance and utility to the skins. Even oil colors, for painters' purposes, form an item in the yearly exports from Britain, of the value of £250,000, and when we calculate the large amount of cotton, silk and wool worked up, most of which requires various coloring agents, gums, starches, and mordants;—that nearly 30,000 tons of hides are annually imported, exclusive of those obtained from English slaughter-houses, besides goat, seal, and other skins—and that the English exports of the various manufactures of cotton, linen, silk, wool and leather in 1852, setting aside home consumption, amounted to nearly fifty millions sterling, we shall be able to form a better estimate of the importance of the various subjects we are now to notice. Great Britain does not pay less than £600,000 annually for the dried carcasses of the tiny cochineal insect, while the produce of another small insect, that which produces the lac dye, is scarcely less valuable. Then there are the gall nuts used for dyeing and making black ink. Upwards of £3,000,000 is paid for barks of various kinds for tanners' purposes, about one million for other tanning substances and heavy dye woods, besides about £200,000 for various extracts of tannin, such as Gambier, Cutch, Divi-divi, and Kino. The aggregate value of the dye stuffs and gum it is difficult to estimate. The beautiful specimens of materials imported from China, India, New Zealand, the Continent, and other countries, and exhibited at the Crystal Palace, proved to England that she has yet much to learn from other nations in the art of fixing colors and obtaining brilliant dyes. The French are much superior in dyeing and the production of fast and beautiful colors. Their chemical researches and investigations are carried out more systematically and effectively than those of Britain. Russia imports dyewoods and dyestuffs to the value of five millions and a half of silver roubles annually. It was well observed by the Jury Reporters at the Great Exhibition, that "a vast number of new coloring materials have been discovered or made available, and improved modes have been devised of economically applying those already in use; so that the dyer of the present time employs many substances of the very existence of which his practical predecessors were wholly ignorant. From the increased use of many of the vegetable colors, and from the improved modes of applying the coloring matters, a demand has naturally sprung up for various dye stuffs: and at the present time, many of the dyeing materials of distant countries are beginning to excite the attention of practical men; for though they have been acquainted with many of these substances, it is only recently that the progress of the art has rendered their use desirable or even practicable." It would be quite impossible, within due limits to make even a bare enumeration of the various plants and trees from which coloring substances and dye stuffs can be obtained: we must, therefore, be content to specify only a few. The roots of some species of Lithospermum afford a lac for dyeing and painting. Dried pomegranates are said to be used in Tunis for dyeing yellow; the rind is also a tanning substance. In the "Comptes Rendus," xxxv., p. 558, there is an account by M. J. Persoz, of a green coloring matter from China, of great stability, from which it appears that the Chinese possess a coloring substance having the appearance of indigo, which communicates a beautiful and permanent sea green color to mordants of alumina and iron, and which is not a preparation of indigo, or any derivative of this dyeing principle. As furnished to M. Persoz by Mr. Forbes, the American Consul at Canton, it was in thin plates of a blue color, resembling Japanese indigo, but of a finer grain, differing also from indigo in its composition and chemical properties. On infusing a very small quantity of it in water, this fluid soon

acquired a deep blue color with a greenish tinge; upon boiling and immersing a piece of calico on which the mordants of iron and alumina had been printed, it was dyed a sea green color of greater or less intensity according to the strength of the mordant—the portions not coated remaining white. This dye as investigated by Mr. Fortune will be further noticed below. A berry called *Makleua* grows on a large forest tree at Bankok, which is used most extensively by the Siamese as a vegetable black dye. It is merely bruised in water, when a fermentation takes place, and the article to be dyed is steeped in the liquid and then spread out in the sun to dry. The berry, when fresh, is of a fine green color, but after being gathered for two or three days it becomes quite black and shrivelled like pepper. It must be used fresh, and whilst its mixture with water produces fermentation. See DIOSPYROS MOLLIS. The bark of *Datisca cannabina* also dyes yellow. It contains a bitter principle, like quassia. A coloring matter is prepared from the dried fruit of the *Rottlera tinctoria*, by the natives of the East, to dye orange, which is a brilliant and tolerably permanent dye. It is apparently of a resinous nature. Turmeric is now imported to the extent of upwards of 800 tons, a portion of this is used in dyeing. The bark and roots of the berberry are used in the East to dye yellow; the color is best when boiled in ley. Some of the species of Symplocos, as *S. racemosa*, known as lodh about the Himalaya mountains, and *S. tinctoria*, a native of Carolina, are used for dyeing. The scarlet flowers of *Butea frondosa* (the Dhak tree), and *B. superba*, natives of the Indian jungles, yield a beautiful dye, and furnishing a species of kino (*Pulas kino*), are also used for tanning. *Althea rosea*, the parent of the many beautiful varieties of hollyhock, a native of China, yields a blue coloring matter equal to indigo. Indigo of an excellent quality has been obtained in the East from a twining plant, *Gymnema tingens* or *Asclepias tingens*. The juice of the unripe fruit of *Rhamnus infectorius*, *catharticus* and *virigatius*, known as Turkey or French berries, is used for dyeing leather yellow. When mixed with lime and evaporated to dryness, it forms the color called sap-green. A great quantity of yellow berries are annually shipped from Constantinople; 115 tons were imported into Liverpool in 1853. The average annual imports into the United Kingdom are about 450 tons. They come from the Levant in hair bales weighing three and a quarter cwt., or in tierces of four to five cwt., and are used by calico printers for dyeing a yellow color. They are sometimes called Persian berries. It is a subject of surprise that the common betel-nut of the East has never been introduced for dyeing purposes. The roots of the awl tree of Malabar and other parts of India, *Morinda citrifolia*, and of *M. tinctoria*, found abundantly in all the Asiatic islands, are extensively used as a dye stuff for giving a red color. It is usually grown as a prop and shade for the pepper vine and coffee tree. The coloring matter resides principally in the bark of the roots, which are long and slender, and the small pieces are the best, fetching 8s. to 10s. a maund. It is exported in large quantities from Malabar to Guzerat, and the northern parts of Hindostan, but seldom finds its way to Europe. The wood and roots of another species, *M. umbellata*, known in the eastern islands as "Mangkudu," are used extensively for their red dye, in Celebes and Java. Specimens of all these, and of the Lopisip bark, bunchong bulu wood, and the gaju gum (from undescribed plants), have been introduced into England. They are said to furnish excellent dyes in the Asiatic islands. Native dyes from Arracan have also been imported, viz., thittel and the-dan yielding red dyes, ting-nget and reros, affording dark purple dyes; and thit-nan-weng, a chocolate dye. These would be worth enquiry, and particulars of the plants yielding them, the quantities available, and the prices might be procured. Dyes and colors from the following plants are obtained in India: several species of *Terminalia*, *Semecarpus anarcardium*, *Myrica sapida*, *Nelumbium speciosum*, *Butea frondosa*, and *Nyctanthes arbortristis* The bunkita barring, obtained from an undescribed plant in Borneo, produces a dark purple or black dye. A species of Ruellia, under the name of "room," is employed in its raw state by the Khamptis and Lingphos to dye their clothes of a deep blue. It is described by the late Dr. Griffiths as "a valuable dye, and highly worthy of attention." It might, perhaps, be usefully employed as the ground for a black dye. In Nepaul they use the bark of *Photinia dubia* or *Mespilus bengalensis* for dyeing scarlet. The bark of the black oak, *Quercus tinctoria* and its varieties, natives of North America, are used by dyers under the name of quercitron. In the south of Europe, *Daphne gnidium* is used to dye yellow. The root of reilbon, a sort of madder in Chili, dyes red. A purple tint or dye is obtained from the bark of an undescribed tree, known under the name of "*Grana ponciana*," growing about Quito, and Stevenson (Travels in South America) says, "if known in Europe, it would undoubtedly become an article of commerce." Another much more expensive species of coloring matter (red) is obtained in various parts of South America from the leaves of the *Bigonia chica*, a climbing evergreen shrub, native of the Orinoco country, with large handsome panicles of flowers. The coloring substance is obtained by decoction, which deposits, when cool, a red matter; this is formed into cakes and dried. Dr. Ure thinks it might probably be turned to account in the arts of civilization. The order of plants to which it belongs, contains a vast number of species, all natives of tropical regions, and their value for the

production of coloring substances may be worth investigation. It is met with in British Guiana, and the Indian tribes of that district prepare the pigment with which they stain their skin from it; it is called by them "Caraveru." The coloring matter is used as a dye in the United States, and for artistical purposes would rival madder. Sir Robert Schomburgk thinks it might form an article of export if it were sufficiently known, as its preparation is extremely simple. The leaves are dried in the sun, and at the first exposure, after having been plucked from the vine which produces them, they show the abundant feculent substance which they contain.

Lana Dye.—A beautiful bluish-black color, known as "Caruta," is procured in Demerara and Berbice from the juice of the fruit of the *Genipa americana*, Linn.—a tree very common in the colony. The Indians use it for staining their face and persons. The Lana dye was honorably mentioned by the jurors at the Great Exhibition in 1851. The bluish-black color obtained from it is remarkably permanent, a fact which has very long been known, though hardly any attempt appears to have been made to introduce it to the notice of European dyers. Another pigment is prepared by them from arnotto, mixed with turtle oil, or carap oil, obtained from the seeds of the *Carapa guianensis* (Aubl.) The wild plantain (*Urania guianensis*) and the cultivated plantain (*Musa paridisiaca*), the Mahoe (*Thespesia populnea*), and the pear seed of the Avocado (*Persea gratissima*), furnish dyes in various parts of the West Indies; specimens of many of these have been imported from British Guiana and Trinidad. Russia produces good specimens of the wood of *Statice coriaria*, the leaves and bark of sumach, the bark of the wild pomegranate, yellow berries, *Madia sativa*, saffron, safflower and madder roots for dyeing purposes. *Avicenna tomentosa*, a species of mangrove, is very common about the creeks of Antigua, Jamaica, and other West India islands, where it is used for dyeing and tanning. In New Zealand, the natives produce a most brilliant blue-black dye from the bark of the Eno, which is in great abundance. Some of the borders of the native mats, of a most magnificent black, are dyed with this substance. It has been tried in New South Wales; but, as with other local dyes, although found well suited for flax, hemp, linen, or other vegetable productions, it could not be fixed on wools or animal matter. Dr. Holroyd, of Sydney, some time since, imported a ton of it for a friend near Bathurst. It is of great importance that chemical science should be applied to devise some means of fixing this valuable dye on wool. As the tree is so common, the bark could be had in any quantity at about £3 10s. a ton; and our tweed manufacturers are in great want of a black dye for their check and other cloths. The principal heavy woods used for dyeing are fustic, logwood, Nicaragua wood, barwood, camwood, red Sanders wood, Brazil wood, and sappan wood.

Red Sanders wood. (*Pterocarpus santalinus*), which is hard and of a bright garnet red color, is employed to dye a lasting reddish brown on wool. It only yields its color to ether or alcohol. The tree, which is a lofty one, is common in the Madras Presidency and other parts of India; it is also indigenous to Ceylon, Timor, and other Eastern islands. The exports of this wood from Madras in one year have been nearly 2,000 tons. The imports of red Sanders wood from Calcutta and Bombay, chiefly into London, are to the extent of 700 or 800 tons a year, worth £6 to £9 per ton. Of FUSTIC, England imports from 1,500 to 2,000 tons annually, and derives its supplies from Brazil, Tampico, Puerto Cabello, Cuba, and Jamaica. The best is obtained from Cuba; for while the common white fustic from Jamaica and the Spanish Main fetches only £5 10s. to £6 10s. the ton, that of Cuba realizes from £8 to £9 10s. the ton. *Sappan Wood* (*Cæsalpinia sappan*) is an article of considerable commerce in the East. It is the bukkum wood of Scinde, and is procured in Mergui, Bengal, the Tenasserim Provinces, Malabar and Ceylon. In 1842 as much 78,000 cwts. were shipped from Ceylon, but the export from thence has decreased. This island, however, ships dyewoods annually to the amount of £2,000. A large quantity is exported from Siam and the Philippine Islands; as much as 200,000 piculs annually from the former, and 23,000 piculs from Manila. 3,524 piculs were shipped from Singapore in 1851, and 4,074 piculs in 1852. The picul is about one cwt. and a quarter. Sappan wood yields a yellowish color, like that of Brazil wood (*C. brasiliensis*) but it does not afford of dye matter so much in quantity or so good in quality. It forms a large export from Ceylon; the shipments from thence were, in 1842, 77,694 cwt.; in 1843, 1,692; in 1844, 2,592; in 1845, 2,854. In 1837, 23,695 piculs of sappan wood, and 2,266 piculs of roots of ditto were shipped, and in the first six months of 1843, 22,326 piculs were exported from Manila; a large portion of this comes to Europe, but some goes to China, the United States, Singapore, &c. 15,500 piculs were shipped from Manila in 1844, 5,250 ditto in 1845: and 1,210 tons in 1850. About 3,000 piculs of sappan wood and the same quantity of other dyestuffs are annually imported into Shanghae. The price of straight sappan wood at Shanghae in July last year, was thirty dollars per picul. In Calcutta, in June 1853, 4,000 piculs of the root of Manila sappan wood sold freely at about 7s. 6d. per factory maund; Siam ditto 6s. 75 tons were imported into Liverpool in 1849: and 120 tons in 1850, from Calcutta. The imports of sappan wood into the United Kingdom, in 1850

amounted to 3,670 tons, worth £8 to £12 the ton, and this continued the price in January 1853. Camwood, red sanders wood, barwood, and other dye woods, are found in great quantities in many parts of Africa. The dyes of Africa are found to resist both acids and light, properties which no other dyes seem to possess in the same degree. About thirty miles east of Bassia Cove, in the republic of Liberia, is the commencement of a region of unknown extent, where scarcely any tree is seen except the camwood. This boundless forest of wealth, as yet untouched, is easily accessible from that settlement; roads can be opened to it with little expense, and the neighbouring kings would probably give their co-operation to a measure so vastly beneficial to themselves. It is impossible to ascertain the exact amount of export of these commodities to Europe and the United States, but it is very great, and employs a large amount of vessels. One Liverpool house imported 690 tons in a single year, worth £9,000.

Dyewoods imported in 1850.	Tons.	Re-exported. Tons.
Logwood,	32,930	4,332
Fustic,	9,808	1,771
Nicaragua	7,909	112
Barwood,	1,896	1,229
Sappan	3 670	—
Green Ebony, and Cocuswood,	1,457	—
Red Sanders,	656	—
Camwood,	416	—
Brazil and Brazillito	309	—
	59,051	7,444

Thus we perceive the annual consumption of heavy dyewoods in Britain, in dyeing cotton, linen, woollen and silk goods, &c., exceeds in weight 51,000 tons.

Arnotto.—The plants of this family are chiefly natives of the warmest parts of South America, the East and West Indies, and Africa. In America, the seeds are called achote or roucou. From the port of Barcelona, in Venezuela, about 2,000 quintals are annually exported. The species grown for its dye is the *Bixa orellana*. It is used to impart a bright orange color to silk goods, and to afford a deeper shade to simple yellows. The dry hard paste is also found to be the best of all ingredients for giving a golden tint to cheese or butter. A convenient liquid preparation is now sold to dairymen. The Spanish Americans mix it with their chocolate, to which it gives a beautiful rich hue.

Safflower was shown in the Great Exhibition from Celebes, Assam, the vicinity of Calcutta, Dacca, the states of Rajpootana, and other places. There are two species: *Carthamus tinctorius*, which has small leaves and an orange flower; and *C. oxyacantha*, with larger leaves and a yellow flower, a native of Caucasus. The former is cultivated in Egypt, the Levant, &c., where it forms a considerable article of commerce. 6,633 cwts. of safflower were imported into the United Kingdom in 1835, of which about one-half was retained for home consumption. Of 5,352 cwts. imported in 1840, nearly the whole came from British possessions in the East. In 1847, about 405 tons were imported; in 1848, 506 tons; in 1849, 407 tons; in 1850, 522 tons. The price of safflower varies from £1 to £8 per cwt., according to quantity. That from Bombay is least esteemed, fetching only 20s. to 30s. The annual quantity of safflower, according to Dr. Taylor, exported from the district of Dacca for eight years ending with 1839, amounted to 4,000 maunds, or about 149 tons. The exports through the Calcutta Custom House are occasionally large: in 1824-25 there were about 316 tons; 8,500 Indian maunds were shipped from Calcutta in each of the years 1841 and 1842. The prices in the Liverpool market, in January 1853, were for Bengal, good and fine, £6 to £7 10s. per cwt.; middling, £4 to £4 10s.; inferior and ordinary, £2 10s. to £3.

Gamboge is extensively used as a pigment, from its bright yellow color. There are two kinds known in commerce, the Ceylon and the Siam. The former is procured from the *Hebradendron Cambogoides*, Graham; a tree which grows wild on the Malabar and Ceylon coasts, and affords the coarsest kind. The pipe gamboge of Siam is said to be obtained from the bruised leaves and young branches of *Stalagmites cambogoides*. The resinous sap is received into calabashes, and allowed to thicken, after which it is formed into rolls. Several other plants, as the *Mangostana gambogia*, Gaertner, and the *Hypericum baccifer-um* and *Cayanense*, yield similar yellow viscid exudations, hardly distinguishable from gamboge and used for the same purpose by painters. The *Garcinia elliptica*, Wallich, of Tavoy and Moulmein, affords gamboge, and approaches very closely in its characters to Graham's *Hebradendron*. In like manner the Mysore tree bears an exceedingly close resemblance to that species. It is common in the forests of Wynaad in the western part of Mysore, and has been named by Dr. Christison *Hebradendron pictorium*. Another gamboge tree has recently been found inhabiting the western Burmese territories. Both these seem to furnish an equally fine pigment. As it can be obtained in unlimited quantity, it might be introduced into European trade, if the natives learn how to collect it in a state of purity, and make it up in homogenous masses in imitation of pipe gamboge, the finest Siam variety. It seems to possess more colouring matter, more resin and less gum than the ordinary gamboge of commerce. Gamboge owes its color to the fatty acid. The resin must be regarded as the chief constituent, and is most abundant in that imported from Ceylon, which contains about 76 per cent., and is therefore best adapted for painting. Gamboge also has its medicinal uses.

DYES, DYEING.

Lichens.—Various species of *Lecanora*, particularly *L. tarterea*, known as cudbear, are used in dyeing woollen yarn. The *Rocella tinctoria* and *fusiformis* furnish the orchil, or orchilla weed of commerce, which is sometimes sold as a moist pulp, but usually in the form of dry cakes, known under the name of *litmus*; it produces a fine purple color. Our imports, which have amounted to 6,000 or 7,000 cwts. annually, are derived chiefly from the Canary, Azores, and Cape Verd Islands. Rock orchilla was shown at the Exhibition of 1851; from the Berlingen Isles, from Angola, Madeira and the Cape de Verds. Orchilla weed is very plentiful about the shores of the islands of New Zealand, some being sent from thence to the Exhibition; but from a want of knowledge as to the time at which it should be gathered, and the mode of preparing it for the market, it has not yet become a saleable commodity. The rich varieties of lichens on the rocks and plains of Australia have not been tested, as they ought to be, with Helot's lichen test. Various lichens, and *Rocella tinctoria*, from Tenasserim and other parts of India, have been introduced by the East India Company. In the Admiralty instructions given to Capt. Sir James C. Ross, on his Antarctic voyage, a few years ago, his attention was specially called to the search and enquiry for substitutes for the *Rocella*, which is now becoming scarce. A prize medal was awarded, in 1851, to an exhibitor from the Elbe for specimens of the weed, and an extract of red and violet orchil. Specimens of varieties of the lichens used in the manufacture of cudbear, orchil and litmus, and of the substance obtained, were also shown in the British department, which were awarded prize medals.

Indigo.—The plants which afford Indigo dye grow chiefly in the East and West Indies, in the middle regions of America, in Africa and Europe. They are all species of the genera *Indigofera*, *Isatis* and *Nerium*. *Indigofera tinctoria* or *cærulea*, furnishes the chief indigo of commerce, and affords in Bengal, Malabar, Madagascar, the Isle of France, and St. Domingo, an article of middling quality, but not in large quantity. The *Indigofera disperma*, a plant cultivated in the East Indies and America, grows higher than the preceding, is woody, and furnishes a superior dye-stuff. The Guatemala indigo comes from this species. *Indigofera Anil* grows in the same countries, and also in the West Indies. The *Indigofera argentea*, which flourishes in Africa, yields little indigo, but it is of an excellent quality. *I. pseudo-tinctoria*, cultivated in the East Indies, furnishes the best of all. *I. glauca* is the Egyptian and Arabian species. There are also the *cinerea*, *erecta* (a native of Guinea), *hirsuta*, *glabra*, with red flowers, species common to the East, and several others. The *Wrightia tinctoria*, of the East Indies, an evergreen, with white blossoms, affords some indigo, as does the *Isatis tinctoria*, or Woad, in Europe, and the *Polygonum tinctorium*, with red flowers, a native of China. *Baptista tinctoria* furnishes a blue dye, and is the wild indigo of the United States.

Sources of supply.—Indigo is at present grown for commercial purposes in Bengal, and the other provinces of that Presidency, from the 20th to the 30th deg. of north latitude; in the province of Tinnevelly and others in the Madras Presidency; in Java, in the largest of the Philippine islands, in Guatemala, Caraccas, Central America and Brazil. Bengal is, however, the chief mart for indigo, and the quantity produced in other places is comparatively inconsiderable. It is also still cultivated in some of the West India islands, especially St. Domingo, but not in large quantities. Indigo grows wild in several parts of Palestine, but attention seems not to have been given to its cultivation or collection. On most parts of the eastern and western coasts of Africa, it is indigenous; at Sierra Leone, Natal, and other places it is found abundant.

Madder.—This substance, which is so extensively used in dyeing red, is the product of the long slender roots of the *Rubia tinctorium*, a plant of which there are several varieties. The principal supplies of this important article of commerce are obtained from Holland, Belgium, France, Turkey, Spain, and the Balearic Isles, the Italian States, India, and Ceylon. The plant is generally raised from seed, and requires three years to come to maturity. It is, however, often pulled in eighteen months without injury to the quality; the quantity only is smaller. A rich soil is necessary for its successful cultivation, and when the soil is impregnated with alkaline matter, the root acquires a red color; in other cases it is yellow. The latter is preferred in England, from the long habit of using Dutch madder, which is of this color, but in France the red sells at two francs per cwt. higher, being used for the Turkey-red dye. Madder does not deteriorate by keeping, provided it be kept dry. It contains three volatile coloring matters, madder purple, orange, and red. The latter is in the form of crystals, having a fine orange red color, and called Alizaine. This is the substance which yields the Turkey-red dye. The chay root is employed in the East Indies as a substitute for madder, and so is the root of *Morinda citrifolia*, under the name of Sooranjee. Turkey madder roots realise about 33s. per cwt. About 1,100 tons are annually shipped from Naples, worth about £30 per ton. Madder has become an article of great request, on account of the fine scarlet color produced from its roots, and is so essential to dyers and calico printers that without it they cannot carry on their manufactures. It is cultivated extensively in Holland, from whence it is imported in large quantities into both England and France, though it is cultivated to some extent in both countries. Madder is extensively grown on the central table land of Affgha-

DYES, DYEING.

nistan, forming one of the leading products of Beloochistan; and, according to Mr. Pottinger, it sells in the Kelat bazar at about 10 lbs. for 2s. The cultivation there pursued is as follows:—The ground is repeatedly ploughed, and laid out finally in small trenches, in which the seed is sown, covered slightly with earth, and then the whole is flooded. Whilst thus irrigated, the trenches are filled with a mixture of rich manure and earth. The plants appear in about ten days, and attain a height of three or four feet during the first summer. They are cut down in September and used as fodder for cattle. Subsequently, and until spring arrives, the ground is manured and repeatedly flooded. During the second year's growth, the plants which are intended to produce seed are set apart, but the stems of the remainder are cut every four or six weeks, in order to increase the size and goodness of the roots.

Indian madder.—*Rubia cordifolia*, or *munjestha*, a variety with white flowers, a native of Siberia, is cultivated largely in the East, particularly about Assam, Nepaul, Bombay, Scinde, Quetta, China, &c., for its dye-stuff, and is known as Munjeet. A small quantity is exported from China and India; about 338 Indian maunds were shipped from Calcutta in 1840, and 2,328 in 1841. It fetches in the London and Liverpool markets from 20s. to 25s. and 30s. per cwt., duty free; 405 tons were imported into Liverpool from Bombay and Calcutta, in 1849, and 525 tons in 1850, but none was imported in 1851 and 1852. It was remarked by the Jury in 1851, at the Great Exhibition, that this is a valuable dye-stuff, and hitherto not so well appreciated as it deserves, for some of the colors dyed with it are quite as permanent as those dyed with madder, and even more brilliant. Its use however is gradually increasing, and it is unquestionably well worthy the attention of dyers.

Logwood.—The logwood of commerce is the red heart wood, or duramen, of a fine lofty growing tree (*Haematoxylon campechianum*), growing in Campeachy and the bay of Honduras, and which is also now common in the woods of Jamaica and St. Domingo. It has been introduced into India. It is principally imported as a dye wood, cut into short lengths. We chip, grind, and pack it into casks and bags, ready for the dyers, hatters, and printers' use, who esteem it as affording the most durable deep red and black dyes. It is sometimes used in medicine as an astringent. That grown in Jamaica is least valued; that of Honduras, Tobasco, and St. Domingo, fetches a somewhat higher price; but that imported from Campeachy direct, is the most esteemed. The annual imports into Liverpool are about 1,300 tons from Honduras, 100 from Tobasco, and 1,800 from Campeachy.

Fustic.—This is the common name of a species of dye wood in extensive use, which is obtained from *Maclura tinctoria*, or *Broussonetia tinctoria*, Kunth, a large and handsome evergreen tree, growing in South America and the West Indies. The wood is extensively used as an ingredient in the dyeing of yellow, and is largely imported for that purpose. The quantity entered for home consumption in the united Kingdom was 1,731 tons in 1847, 1,653 in 1848, and 1,842 tons in 1849. Ninety-one tons were shipped from Montego Bay, Jamaica, in the first six months of 1851.

Brazil wood.—This very ponderous wood is obtained in Brazil from the *Caesalpinia braziliensis*, which yields a red or crimson dye, when united with alum or tartar, and is used by silk dyers. It is imported principally from Pernambuco, 1,200 quintals having been shipped to London in 1835, but about 500 tons, worth about £4 a ton, were imported from Costa Rica 1845. The tree is large crooked, and knotty, and the bark is thick, and equal the third or fourth of its diameter. The imports may be stated at about 600 tons annually, the average price being £50 per ton. Brazil wood is found in the greatest abundance and of the best quality in the Province of Pernambuco, but being a government monopoly it has been cut down in so improvident a manner, that it is now seldom seen within several leagues of the coast. It might be introduced into India with advantage.

Lichens.—The chief lichens employed in the manufacture of orchil and cudbear are the following:—Angola weed (*Ramalina furfuracea*). Mauritius weed (*Rocella fusiformis*), which comes also from Madagascar, Lima, and Valparaiso, and then bears the distinctive commercial name of the port of shipment.

Henna (*Lawsonia inermis*), is an important dye-stuff, and the distilled water of the flowers is used as a perfume. The Mahomedan women in Asia use the shoots for dyeing their nails red, and the same practice prevails in Arabia. In these countries the manes and tails of the horses are stained red in the same manner. The *Genista tomentosa* yields red petals used in dyeing, and containing much tannic acid.

Burmese Dyeing. Green-dye plants.—Turmeric, and the leaves of the soap-acacia *Acacia rugata*, afford a beautiful green dye.—*Mason.*

Various red-dye plants.—The rose-coloured fruit of the tamarind "yields a beautiful deep red-colour, approaching purple"; the wood of the *Adenanthera pavonina* dyes red, and the wood of the black varnish tree affords a red dye.—*Mason.*

Various yellow-dye plants.—The wood of the jack, the root of the pyschotria, the bark of the gamboge trees, the flowers of the buteas, the rind of the Bengal quince, and the leaves of the memecylon and the touk-yat, all produce bright yellow dyes.—*Mason.*

Diospyros mollis is the *Black-Dye plant.*—The blossoms of the shoe-flower plant are used by the Chinese to dye leather black, the juice of the cashewtree gives a black to linen, and the fruit of the melas toma affords a black dye.—*Mason.*

The Shan black dye.—This celebrated vegetable dye is made from the fruit of a species of ebony, *Diospyros mollis*, which is said to grow on the mountains that separate the Province of Tavoy from the Siamese territories. Isolated plants may be seen in the gardens of Tavoy, and Maulmain, but I have never seen one in flower,or fruit.—*Mason.*

Javanese Dyeing.—The Javanese, who, of all the Malayan race, have certainly made the highest progress in all the useful arts, have a specific term for dyeing or tinting,—"madal;" but the Malays express it only by the word for dipping, "*chalup.*" Yet the only generic words which either of them possesses for "colour," are the Sanscrit, warna; and the Portuguese, tinta. Their colours are usually sombre,—little varied, but generally fast. Blues are always produced from indigo, yielded for the most part by the Indigofera tinctoria, as in other parts of India, but in Sumatra, occasionally, from the Marsdenia tinctoria, a plant of the natural order of the Asclepiadeæ. Yellows are produced from the woods of two species of Artocarpus, the jack and champadah, and from turmeric; and reds from the bark of the root of the "*mangkudu*," the Morinda umbellata,—from the "*kusumba-java*," safflower or Carthamus tinctorius, from the "*kusumba-kling*," which is the annotto, or Bixa orellana, from the sapang, or sapan-wood, Cæsalpinia sappan, and from the nidus of the lac insect. Black is produced from the rinds of the mangostin fruit, and of the "*Kata-pang*," Terminalia catappa, with sulphate of iron. Sails and nets are dyed, and perhaps also tanned with a wood called in Sumatra "*ubar*" which is the Ricinus tanarius of botanists. The mordants used are rice-bran, alkalis from the combustion of some vegetable matters, as the fruit stalks and mid-ribs of the cocoanut palm and alum brought from China.

Chinese Dyes.—In China, coloring matter used for dyeing blue is derived from two species of plants, the *Polygonum tinctorium* at the South, and the *tien tsing* or *Isatis indigotica*, cultivated at Shanghai and Chusan.—*Williams' Middle Kingdom, vol.* ii. *p.* 106. The Shanghae indigo (Isatis indigotica) is largely cultivated in the Ke-wang-meow district, a few miles to the south. The "Kong-wha," a variety of safflower (carthamus tinctorius), was found for the first time in fields near Cading. This dye, is held in high esteem by the Chinese, and is used in dyeing the red and scarlet silks and crapes which are so common in the country,and so much and justly admired by foreigners of every nation. Large quantities are annually produced in the Che-kiang province near Ningpo. At this season (June 10th) the crop of flowers had been gathered, and all the plants, removed from the land, except some few here and there on the different farms which had been left for seed. The seed was not yet ripe, so that I could not get a supply, but I determined to return that way and secure a portion to send to the Agricultural and Horticultural Society of India, in order to compare the Chinese with the Indian safflower. I believe they have turned out to be alike, or nearly so.—*Fortune.* When Mr. Fortune prepared to take up his late residence in China, his intention was directed, by the Calcutta Agricultural Society, to the Chinese varnish tree, *Rhus* species, the wax-insect tree, *Fraxinus* species, and to the soap-bean tree, *Cæsalpinia* species: to the various trees valuable for their fruit or timber and ornamental plants; but above all to the green indigo (so called), *Rhamnus* species, which yielded a dye that was at that time attracting much attention in France.

Rhamnus—The green-indigo (so called) has been discovered and introduced both to England and to India.—*Fortune's Res. among the Chi. page* 146.

Ruellia indigotica.—In China, in one part of the Chekiang province, and also amongst the Fung-hwa mountains to the westward of Ningpo, there are large quantities of a blue dye produced, which is in fact the indigo of that part of the country. Those who have read my 'Wanderings in China,' published in 1846, may remember the account given there of a valuable kind of Indigo, made from a species of wood (Isatis indigotica) which is cultivated extensively in the level country a few miles to the westward of Shanghae. The kind which attracted Mr. Fortune's attention in Chekiang is equally valuable, if not more so. It is made from a species of Ruellia, which, until it gets a better name, may be called Ruellia indigotica. It is a curious circumstance that the same plant, apparently, has lately been discovered in the Assam country in India, where it is also cultivated for the blue dye it affords. I had an opportunity of examining it in the garden of the Agricultural and Horticultural Society at Calcutta, by whom it had been introduced, and where it was standing alongside of the Chinese kind, to which it certainly bears a most striking resemblance: the point of identity will easily be determined when the plants come into flower. Strange it will be, if it is ultimately found that this species, which produces a dye unknown to commerce, is in cultivation all the way across from the eastern shores of China to the borders of Bengal, and this is far from being improbable. This Ruellia seem to be easily cultivated; it grows most luxuriantly, and is no doubt very productive. Having evidently been found indigenous a little further to the south, in a warmer latitude, it is not hardy in the province of Chekiang, any more than cotton is

about Shanghae; but nevertheless it succeeds admirably as a summer crop. It is planted in the end of April or beginning of May, after the spring frosts are over, and is cleared from the ground in October, before those of autumn make their appearance. During this period it attains a height of a foot or a foot and a half, becomes very bushy, and is densely covered with large green leaves. It is cut down before any flowers are formed. The Chinese method of preserving plants for next year's crop is most ingenious and well worth notice. Being somewhat tender, as I have already remarked, the roots which are left in the ground after the gathering season are all destroyed by the first frosts of winter. But the Chinese cultivator does not depend upon these for the crop of the following year, nor does he take them up or cover them in any way. They have done their duty for one year, and are now left to their fate. Cuttings are found to be much more vigorous and productive than the old roots and to the formation and preservation of these cutting the Chinese cultivator directs his attention. When the stems are cut down for the manufacture of indigo, a sufficient quantity have their leaves stripped off, and are afterwards taken into a house-shed to be properly prepared. The leaves thus stripped from the cuttings are thrown into the tanks with the other stems and leaves, so that nothing is lost, except what is actually required for the purposes of propagation. The stems are now tied up firmly in large bundles, each containing upwards of 1000, and the ends of each bundle are cut across, so as to leave them perfectly neat and even both at top and bottom. These bundles are each about a foot long, and, of course, nearly round. Having been thus prepared they are carried to a dry shed or outhouse, where, in some snug corner, they are packed closely and firmly together, and banked round with very dry loam. A portion of the dry soil is also shaken in between the bundles, and this being done the operation is complete. Should the winter prove unusually severe, a little dry straw or litter is thrown over the surface of the cuttings, but nothing else is required. During the winter months the cuttings remain green and plump; and although no leaves are produced, a few roots are generally found formed, or in the act of forming, when the winter has passed, and the season for planting has come round. In this state they are taken to the fields and planted. The weather during the planting season is generally showery, as this happens about the change of the monsoon, when the air is charged with moisture. A few days of this warm showery weather is sufficient to establish the new crop, which now goes on growing with luxuriance, and requries little attention during the summer, indeed none, except keeping the land free from weeds. In the country where this dye is grown there are numerous pits or tanks on the edges of the fields. These are usually circular in form; and one which I measured was eleven feet in diameter, and two feet in depth. About 400 catties of stems and leaves are thrown into a tank of this size, which is then filled to the brim with clear water. In five days the plant is partially decomposed, and the water has become lightish-green in colour. At this period the whole of the stems and leaves are removed from the tank with a flat-headed broom made of bamboo twigs, an admirable instrument for the purpose. When every particle has been removed, the workmen employed give the water a circular and rapid motion with the brooms just noticed, which is continued for some time. During this part of the operation another man has employed himself in mixing about thirty catties of lime with water, which water has been taken out of the tank for the purpose This is now thrown into the tank, and the rapid circular motion of the water is kept up for a few minutes longer. When the lime and water have been well mixed in this way the circular motion is allowed to cease. Four men now station themselves round the tank and commence beating the water with bamboo rakes made for this purpose. The beating process is a very gentle one; as it goes on the water gradually changes from a greenish hue to a dingy yellow, while the froth becomes of a beautiful bright blue. During the process the head workman takes a paleful of the liquid out of the tank and beats it rapidly with his hand. Under this operation it changes colour at once, and its value is judged of by the hue it presents. The beating process generally lasts for about half an hour. At the end of this time the whole of the surface of the tank is covered with a thick coating of froth of the most brilliant colours, in which blue predominates, particularly near the edges. At this stage, it being desirable to incorporate the froth with the liquid below it, I witnessed a most beautiful chemical operation which took me completely by surprise, and showed how universally must be the knowledge of the effect of throwing "oil upon the waters." A very small portion of cabbage oil only a few drops—was thrown on the surface of the froth, the workmen then stirred and beat it gently with their flat brooms for a second, or two, and the whole disappeared as if by some enchanters wand. And so small a quantity of oil was necessary for this purpose that even when the cup had been emptied, and had only the oil that was necessarily adhering to its edges, it was thrown into another tank, and produced the desired effect. The liquid, which is now darker in colour is allowed to stand quiet for some hours, until the coloring matter has sunk to the lower stratum, when about two-thirds of the surface is drawn off and thrown away. The remaining third part is then drawn into a small square tank on a lower level, which is thatched over

with straw and here it remains for three or four days. By this time the colouring matter has separated itself from the water, which is now entirely drained off—the dye occupying three or four inches of the bottom in the form of a thick paste, and of a beautiful blue colour. In this state it is packed in baskets, and exposed for sale in all the country towns in this part of China. What its intrinsic value may be when compared with the indigo of commerce, I have no means of ascertaining, but it is largely used in this part of the world, where blue is the most fashionable colour, judging from the dresses of the people, and it is possible that with our knowledge of chemistry a colour of this kind might be greatly improved. After being grown and manufactured as I have described, it is sold at rates varying from 50 to 100 cash a catty, say from 2d to 4d per lb. Some is sold as low as 30 cash, but this is very inferior, the greater part produced is sold at from 60 to 80 cash a catty, and it must be of a very superior quality if 100 cash is paid. Like the Shanghae indigo made from Isatis indigotica, it is called "Tien-ching" by the Chinese.

Rhamnus. While upon the subject of Chinese dyes, I shall now give some account of the "green indigo," which has been attracting much notice lately both in India and in Europe. A portion of cotton cloth obtained in China by the French manufacturers being greatly admired on account of the peculiar green of its dye, was submitted to the celebrated chemist M. Persoz with a request that he would endeavour to ascertain the composition of the green colour. The following is a translation of this report upon this subject to the Academy of Sciences:—Every attempt that I made upon the specimen to detect evidence of the presence of a blue or yellow failed, and I was led to the conviction, by isolating the coloring principle, that the green was produced by a dyeing material of a peculiar nature and sui generis. It further was evident,

1st.—That the coloring matter was an organic product of vegetable origin.

2nd.—That the fabric on which it was fixed was charged with a strong dose of alum and a little oxide of iron and lime, bodies the presence of which necessarily implied that mordants had been used in dyeing the calico.

These results were so positive, and at the same time so opposed not only to everything known in Europe regarding the composition of green colour, but also to all that is recorded by writers regarding the dyeing processes employed in China for the production of green, that I was induced to go into a more detailed investigation of the subject; and about the end of last November I applied to Mr. Forbes, the American Consul at Canton, for some of this valuable material. I am indebted to his kindness for a specimen weighing about one gramme (15½ grains). The substance is met with in thin plates, of a blue colour, having a strong analogy with that of Java indigo, but of a finer cake and differing besides from indigo both in its composition and in all its chemical properties. On infusing a small fragment of the substance in water, the liquid speedily became coloured of a deep blue with a shade of green. After the temperature had been raised to the boiling point, a piece of calico, prepared for printing with mordants of alum and oxide of iron, was dipped in it and a true dye was the result. The following appearances were observed. The portion of the fabric to which alum had been applied showed a deep green, of more or less intensity, according to the strength of the mordant. The portions charged with both alum and oxide of iron yielded a deep green, with a shade of olive. The portions charged with oxide of iron alone yielded a deep olive. The parts of the cloth where no mordant had been applied remained sensibly paler. The colours thus obtained were treated with all the re-agents to which the Chinese calico had in the first instance been subjected, and they behaved in precisely the same manner. From these experiments it may be inferred,

1st. That the Chinese possess a dye-stuff presenting the physical aspect of indigo, which dyes green with mordants of alum and iron.

2nd. That this dye stuff contains neither indigo nor any thing derived from that dyeing principle. Mons. Legentil, President of the Chamber of Commerce of Paris, having perceived the importance of France being speedily put in possession of this valuable material, with a view to the interests of science and of industry, took the necessary steps, several months ago, for procuring a suitable quantity with the least possible delay, and at the same time to have inquiries made as to its origin and mode of preparation. Mr. Fortune here adds, that the investigation of the green dye-plant, exhibit as many amusing blunders as used to be made about the Chinese rice-paper plant in former days. By some the flowers of the Whi-mei (Sophora japonica) were sent home as the "green indigo," but this plant yields a yellow dye and even when mixed with blue to make a green, the green is not that kind noticed by the French manufacturers. At another place he says, here I found fields under cultivation with a kind of Rhamnus apparently. The Chinese farmer called it "Loh-zah, or "Soh-loh-shoo," and showed me samples of the cloth which had been dyed with it. To my delight these samples corresponded exactly with those sent back from France one of which was in my possession, but he told me that two kinds were necessary—namely the variety they cultivated in their fields and one which grew wild on the hills—in order to produce the dye in question. The former they called the yellow kind and the latter the

white kind. The dye itself was not extracted by them; they were merely the growers, and therefore I could get no information as to its manufacture. I however secured a good supply of plants and seeds of both kinds, which were afterwards sent to India and England. My further inquiries on the subject of the manufacture of the "green indigo" were conducted in connexion with Dr. Lockhart and the Rev. J. Edkins, of Shanghae. We found that a considerable portion of this dye was made near a city called Kia-hing-foo, situated a few miles west from Shanghae and Mr. Edkins procured a bundle of chips there, which exhibited the state in which the article is sold in the market. Since I left China I have received the following interesting letter from Dr. Lockhart, which throws much light on the subject. The information was procured by Mr. Edkins and may therefore be fully relied upon. "The bark of two kinds of the tree known as the 'green shrub' (Luk-char), one wild, which is called the white and another cultivated, which is called the yellow, are used to obtain the dye. The white bark tree grows abundantly in the neighbourhoods of Kea-hing and Ningpo; the yellow is produced at Tsah-kou-pang, where the dye is manufactured. This place is two or three miles west from Wang-steen, a market-town situated a little to the south of Kea-hing. "The two kinds are placed together in iron pans and thoroughly boiled. The residuum is left undisturbed for three days, after which it is placed in large earthenware vessels, and cotton cloth, prepared with lime, is dyed with it several times. After five or six immersions the colouring matter is washed from the cloth with water, and placed in iron pans to be again boiled. It is then taken up on cotton yarn several times in succession, and when absorbed in this way it is next washed off and sprinkled on thin paper. When half dry the paper is pasted on light screens and strongly exposed to the sun. The product is called Lukkaou. In dyeing cotton cloth with it, ten parts are mixed with three parts of subcarbonate of potash in boiling water. "The dye made at Tsah-kou-pang is not used to dye silk fabrics, because it is only a rough surface which takes it readily. To colour silk with it, so much of the material must be used that it will not pay. All cotton fabrics, also grass-cloths, take the colour readily. The dye does not fade with washing, which gives it a superiority over other greens. "It is sent from Kea-hing as far as Shanting. It is also made in the province of Hoonan and at Ningpo, but the dye at these places is said to be of an inferior quality. It has long been used by painters in water-colours, but the application of it to dye cloth was first made only about twenty years ago. If some method could be discovered of applying it to silk fabrics it would become still more useful." The information obtained by Mr. Edkins on this subject is, no doubt, perfectly correct. It agrees in the most important particulars with what I had gleaned from time to time amongst the Chinese in various parts of the country. The chips he brought with him from Kea-hing were identical with the "Soh-loh," or "Loh-zah" (Rhamnus sp.), which I have already mentioned, and his statement that two varieties of the plant are used to produce the dye agrees with my own observations. The mode of extracting the dye from the bark or wood (for both seem to be used), as practised by the Chinese, appears to be slow and tedious, but with our superior knowledge of chemistry this might possibly be improved. From these investigations it would appear that two colouring principles are necessary to the production of this dye. This however, will not affect the value of it as a rich and permanent green, a quality which has been appreciated by the French manufacturers, and which is also well known to the Chinese.—*Fortune's Res. among the Chinese, page* 167.

E

(3303) EAGLE-WOOD.

Eagle-wood; ENG; Aloe-wood.
Agila, Gahru, Kayu gahru, MALAY.
Kalambak, MALAY and JAVANESE.
Agarhu, SANSCRIT.

One of those substances of which the name, from similarity of sound in a foreign language, has been converted into another having no reference to its original signification. It is a highly fragrant wood, much esteemed by Asiatics for burning as incense, and known in Europe by its present designation ever since the Portuguese visited and imported the substance direct from the Malayan islands and the kingdom of Siam, where it has always been abundant, and long established as an article of commerce. The Malayan name is Agila, whence the wood was called Pao-d' Agila, by the Portuguese, and has since been converted into Pao-d' Aguila and Pao-d' Aquila, Bois-d'Aigle, Eagle-Wood, and Agel-Hout. From the Malayan Agila has probably been derived the Sanscrit Agara, whence we have the Hindoo Aggur, if not from the more familiar appellation of Garoo, by which Eagle-Wood is also known in the Malayan Archipelago. In Persian works on Materia Medica in use in India, we learn from Dr. Royle ('Illustr. of

Himal. Bot.' &c.) that several kinds of fragrant wood are described under the Arabic name Aod (Haud and Ud of Garcias), and that he himself obtained three kinds in the bazars of India, called Aod-i-Hindee, Aod-i-Chinee, and Aod-i-Kimaree (evidently the Al-Cemericum of Arabian authors); and that with the above Hindoo, a Greek synonym, Agallochee, is also given, and more especially applied to Aod-i-Kimaree, which is also called Aod-i-Bukhoor, Incense-Wood. As Agallochee is no doubt a corruption of the Agallochum of Dioscorides, described by him as a fragrant wood from India and Arabia, it is interesting to find that the translators from the Greek into the Arabic of the school of Baghdad settled these synonyms at a time when they must have been well acquainted, from their profession and position, with the substances to which both the Greek and Arabic names were applied. Serapion and Avicenna describe several kinds of this fragrant wood, and the latter under both Agalugen or Aghaloojee, and Aod, which in the Latin version is translated Xyloaloe, a name that was applied by the latter Greek medical writers to Agallochum, whence we have lignum aloes, lign-aloe, and aloes-wood, the origin of which it is difficult, if not impossible, to ascertain, unless we suppose it to be a corruption of Agila: for the bitter, scentless, spongy-textured stems of the genus Aloe could not afford any substitute for this fragrant wood, or be thought to yield it, at least by the Arabs, who were well acquainted with and accurately describe aloes, and the place, Socotra, where the best kind is found. Though Dioscorides notices only one, which some suppose to be the Tarum of Pliny, several kinds of Agallochum are described by Serapion and Avicenna, which, as it is not possible at present to identify, it is unnecessary to notice, and therefore we shall refer only to the three kinds which have been traced to the trees yielding them, by naturalists who have visited the countries where these are indigenous.

An *Aguila brava* (wild) is mentioned by Garcias, as produced near Cape Cormorin, in the southern part of the Indian peninsula, and in the island of Ceylon; but the tree yielding this wood has not been ascertained. Rumphius ('Herb. Amb.' ii. p. 40,) describes two kinds of *Agallochum spurium*, found in Borneo and Sumatra, one of which he calls Garo Tsjampica, which is described as having leaves and flowers resembling those of the celebrated champa (Michelia champaca), and may be a species of the same genus. A third kind of spurious Agallochum, he describes in another part of his work, as the produce of his Arbor excæcans, so called from the acridity of its juice blinding people, and which is the Excæcaria agallocha of Linnæus. Considering that Rumphius, in originally describing this tree, has said "Lignum hoc tantam cum agallocha similitudinem," and as affording a substitute for that substance, it is not surprising that it should be frequently quoted as the tree which yields the genuine agallochum or aloes wood. Fee (Hist. Nat. Pharm.) states that he had seen a genuine specimen of the wood of this tree, and that its fragrance cannot be compared with the Agallochum of Loureiro and Dr. Roxburgh mentions that the wood-cutters of the delta of the Ganges, though well acquainted with the highly acrid and very dangerous milky juice of this tree (there called geria), do not mention agallochum, of any kind, being found in it. Of the two kinds of Agallochum which are most valued, and both considered genuine, one is distinguished by the name of Calambac, and the other as the Garo of Malacca.

The first, called Calambac, and Agallochum Primarium by Rumphius, appears, as far as hitherto known, to be a native of Cochin-China only, growing on the mountains of that country in about 13° N. lat., near the great river Lavum, which may be the Meikeng flowing between Cochin-China and the Laos. This tree was named *Aloexylum agallochum* by Loureiro, 'Fl. Cochin-Chinensis,' p. 327, and placed by him in *Decandria Monogynia*, and described as a lofty tree with erect stem and branches, long lanceolate shining leaves, terminal bunches of flowers, with a woody falcate 1-seeded pod for its fruit, whence it is referred by De Candolle to the natural family of *Leguminosæ*. Loureiro states that the wood of this tree is white and inodorous, and that its fragrance is the result of disease, when the oily portions thicken into resin in the central parts of the tree, and that no part of the tree is milky or poisonous, but that paper is made from its bark in Cochin-China, as in Japan from that of the mulberry.

The next kind of Agallochum is that commonly called Garos, and to which the name of Eagle-Wood is more frequently applied, and which has long been an article of export from Malacca and the kingdom of Siam. Specimens of the tree which yields this were first obtained by M. Sonnerat in his second voyage to India, from which probably have been given the figure and description by Lamarck. ('Enc. Meth.,' i. p. 49, Illustr. t. 376.) The plant he named *Aquilaria malaccensis*. This, the Garo de Malacca, was introduced by Dr. Roxburgh into the botanic garden of Calcutta, and was not to be distinguished from specimens of a tree called Ugoon, which is a native of the mountainous tracts east and south-east from Silhet, between 24° and 25° of N. lat., which flowers in April, and ripens its seed in August, and which he says there can be little or no doubt furnishes the real Calambac or Agallochum of the ancients; adding, that there seems more reason to think that it was carried to China from our eastern frontier, than to suppose it was carried from Cochin-China, or any other country in the vicinity of China, where it has always been

in great demand. Small quantities are sometimes imported into Calcutta by sea, from the eastward; but such is always deemed inferior to that of Silhet. ('Fl. Ind.' ii. p. 423.) As the Malacca plant had not flowered, Dr. Roxburgh was unable to decide that they were positively the same with those from Silhet, and therefore named these *Aquilaria agallocha*, as another species of the same genus. By this name it has been figured in Royle's 'Illustr.' i. 36, f. 1, from a drawing by Dr. Hamilton of a plant which he called *Agallochum officinarum*, and which he found near Goalpara, on the eastern frontier of Bengal. This drawing is illustrated with dissections by Dr. Lindley. The fragrant nature of genuine Agila or Eagle-Wood is well known, and that it has from very early periods been employed both by the natives of India and of China as incense. Mr. Finlayson, in his visit to Siam, says that the consumption of this highly odoriferous wood is very considerable in Siam, but that the greatest part is exported to China, where it is used in a very economical manner. The wood being reduced to a fine powder, and mixed with a gummy substance, is laid over a small slip of wood, about the size of a bull-rush, so as to form a pretty thick coating. This is lighted, and gives out a feeble but grateful perfume. French authors inform us that the Eagle-Wood was burned as a perfume by Napoleon in the imperial palace. We cannot conclude this subject without inquiring whether the substances of which we have been treating are the Lign-Aloes of Scripture, Ahaloth, masc. Ahel, whose plural is Ahalim. It would be impossible to do justice to the subject in a small compass, or without referring to the numerous dissertations which have been written on it; but it may be observed, that these might have been much shortened, if the authors had been naturalists, or intimately acquainted with the natural history and usages of eastern countries. Such information would at least have prevented any species of aloe being considered or figured as the far-famed and fragrant Lign-Aloe from a mere similarity in sound. In the present instance, the difficulty is increased by the supposed necessity of reconciling the different passages in which Lign-Aloes are mentioned, as in Numbers, xxiv. 6, where it is mentioned as a tree planted; but in the three other passages, Proverbs, vii. 17, Psalms, xiv. 9, and Canticles, iv. 14, it is enumerated with the most fragrant products of the east as cinnamon, cassia, calamus, camphor, frankincense, myrrh, spikenard, and saffron. Here we may observe, that a substance which was indigenous in a country was not likely to have been an article also of commerce from a far country in those early times; and that therefore, as it is disputed whether the word shall be translated Tents or Lign-Aloes, the word may perhaps be used in a poetical sense, as it is thought to be by some commentators. In the three passages above referred to, it may be noted that, except sandal-wood, there is no other substance which could be so well enumerated with those with which it is found in connection as the Agila-Wood of the East; whether we consider its high price, delicate perfume, or the long time in which it has been held in high estimation, while the similarity of its name is at the same time remarkable.—*Eng. Cyc. Vol.* ii. There can be no doubt but that the perfumed wood under notice is the result of disease in the tree that yields it, produced by the thickening of its sap into a gum or resin. The perfumed wood is found in greatest perfection in the mountainous country to the east of the Gulf of Siam, including Camboja and Cochin-China, between 8° and 14° of North latitude. It is found however, although of inferior quality, as far north as Sylhet in Bengal, and as far south as the Malay peninsula and Sumatra and in all this wide extent the tree, a tall forest one, is probably either the same or of the same natural family. Crawfurd saw it growing, in the healthy and diseased state, in the Mission to Siam and Cochin-China in 1821 and 1822. Crawfurd states it belongs to the Leguminosæ, but that the genus has not been ascertained.—*Crawfurd, p.* 6. Aquillaria malaccensis (the A. ovata of botanists) produces a whitish yellow-wood, also sold under the above name.

(3304) EAGRE, the Eagre, or as it is called in India, the "*Bore*" of the Tsien-tang river, is famous in Chinese history. It is one of the three wonders of the world, according to a Chinese proverb, the other two being the demons at Tang-chan and the thunder at Lung-chan. As in other countries the Eagre or Bore makes its appearance generally on the second or third day after the full or change of the moon or at what are called spring tides and particularly in spring and autumn, about the time the sun is crossing the line. Should it so happen that strong easterly gales blow at these times the Eagre rolls along in all its grandeur and carries everything before it. Dr. Macgowan, the well known medical missionary at Ningpo, gives the following graphic account of it which he witnessed during a visit to Hang-chow-foo. Between the river and the city walls, which are a mile distant, dense suburbs extend for several miles along the banks. As the hour of flood-tide approached, crowds gathered in the streets running at right angles with the Tsien-tang, but at safe distances. On one occurrence the position of Mr. Fortune was a terrace in front of the Tri-wave temple, which afforded a good view of the entire scene. On a sudden all traffic in the thronged mart was suspended; porters cleared the front street of every description of merchandise; boatmen ceased lading and unlading their vessels and put out into the middle of the stream, so that a few minutes

sufficed to give a deserted appearance to the busiest part of one of the busiest cities in Asia: the centre of the river teemed with craft from small boats to large barges, including the gay flower-boats, loud shouting from the fleet announced the appearance of the flood which seemed like a glistening white cable stretched athwart the river at its mouth as far down as the eye could reach. Its noise, compared by Chinese poets to that of thunder, speedily drowned that of the boatmen, and as it advanced with prodigious velocity—at the rate, of twenty-five miles an hour—it assumed the appearance of an alabaster wall or rather of a catract four or five miles, across and about thirty feet high, moving bodily onward. Soon it reached the advanced guard of the immense assemblage of vessels awaiting its approach. Knowing that the Bore of the Hoogly, which scarce deserved mention in connection with the one before me, invariably overturned boats which were not skilfully managed, he could not but feel apprehensive for the lives of the floating multitude. As the foaming wall of water dashed impetuously onwards they were silenced, all being intently occupied in keeping their prows towards the wave which threatened to submerge everything afloat: but they all vaulted, as it were, to the summit with perfect safety. The spectacle was of greatest interest when the eagre had passed about half-way among the craft. On one side they were quietly reposing on the surface of the unruffled stream, while those on the nether portion were pitching and heaving in tumultuous confusion on the flood. Others were scaling with the agility of salmon the formidable cascade. This grand and exciting scene was but of a moments duration; it passed up the river in an instant, but from this point with gradually diminishing force, size and velocity, until it ceased to be perceptible, which Chinese accounts represent to be eighty miles distant from the city. From ebb to flood-tide the change was almost instantaneous. A slight flood continued after the passage of the wave, but it soon began to ebb. The Chinese say that the rise and fall of the tide is sometimes forty feet at Hang-chow. The maximum rise and fall at spring tides is probably at the mouth of the river, or upper part of the bay, where the Eagre is hardly discoverable. In the Bay of Fundy, where the tides rush in with amazing velocity, there is at one place a rise of seventy feet, but there the magnificient phenomenon in question does not appear to be known at all. It is not, therefore, where tides attain their greatest rapidity, or maximum rise and fall, that the wave is met with, but where a river and its estuary both present a peculiar configuration.—*A Res. among the Chi. p.* 317.

(3305) EAR-GULIE, the Tamil name of a Ceylon tree which is about fourteen inches in diameter, and eight feet in height. It is not a useful wood.—*Edye's Ceylon.*

(3306) EARTH NUT. Arachis Hypogea. Ground-nut.

(3307) EARTHENWARE, CROCKERY.

Aardegoed, Dut.	Stoviglie, Terraglie, It.
Vaisselle de terre, Poterie Fr.	Gliniane naczynia, Pol.
Irdene Warren, Ger.	Gorschetschnue possodu, Rus.
Chenecekam, Guz. Hind.	Loza de barro, Sp.

A term generally applied to all utensils composed of earthen materials, known by the distinctive names of porcelain, stone-ware, flint-ware, delft, iron-stone, China ware, &c.—*Faulkner.*

(3308) EAU DE COLOGNE. A celebrated preparation for the toilet, consisting of aromatized alcohol. It is extensively manufactured in France and other parts of the Continent, from silent brandy, mixed with sage, thyme, camphor, cloves, and other herbs and spices, the whole being macerated together, and then distilled.—*Faulkner.*

(3309) EBONY,

Kaya-arang, Malay and Javanese	Abnoos, Guz. Hind.
Kendoo, Beng.	Ebeno, It.
Ebbenout, Dut.	Ebenus, Lat.
Ebene, Fr.	Ebenowoedcrewo, Rus.
Ebenholz, Ger.	Atcha-marum, Tam.

An exceedingly hard and heavy wood, of great durability, and susceptible of a fine polish. There are many varieties of ebony; the best is that which is jet black, free from veins, and close grained; besides the black there are red, green and yellow ebonies, but these are not much esteemed. Ebony is chiefly used in the manufacture of chairs, couches, &c, and in mosaic and other inlaid work. It is procured in Ceylon, Malabar, Zanzibar, Mauritius, and Madagascar.—*Faulkner.* Ebony so called, is found in most of the countries of the Asiatic Archipelago, from the Peninsula and Sumatra to the Philippine Islands. It is there probably the produce of several species of Diospyros, but chiefly of Diospyros melanoxylon. It is greatly inferior in quality to the ebony of Ceylon and the Mauritius, the produce of Diospyros ebenum.—*Crawfurd Dict. page* 135. *See* DIOSPYROS.

(3310) ECHITES, a genus of twining Plants, inhabiting tropical countries, and belonging to the natural order *Apocynaceæ*. They have handsome yellow or white corollas, and are moreover remarkable for their singular fruit, which consists of two divaricating woody pod-like follicles containing a large number of silky seeds. There are above 60 species of this genus. They are dangerous lactescent plants, of no known use.—*Eng. Cyc. p.* 487. Dr. Wight, in Icones, gives Echites acuminata, 424; antidysenterica, 439; caryophyllata, 440; cymosa, 395; dichotoma,

438 ; frutescens, 430 ; hircosa, 429 ; macrophylla, 432 ; marginata, 425 ; paniculata, 596 ; parviflora, 423 ; scholaris, 422 ; venenata, 436.

(3311) ECHITES ACUMINATA, a climbing shrub with white flowers and habit as the next.—*Riddell.*

(3312) ECHITES PANICULATA, a climbing shrub with large yellow showy flowers.—*Riddell.*

(3313) ECHINOPS ECHINATUS, Camel Thistle. *Hind.* Oont-katara. Very common in Rajwarra : camels consume it readily.—*Gen. Med. Top. p.* 206.

(3314) ECHIUM GRANDIFLORUM, BORAGINACEÆ.

(3315) ECLIPTA PROSTRATA, Trailling Eclipta. *Hind.* Bhaugi Key sute. In Ajmeer, this is a common weed in the rains.—*Gen. Med. Top. p.* 200.

(3316) EDGWORTHIA CHRYSANTHA. The curious and much-prized *Edgworthia chrysantha* grows in great abundance in China, as also Reeves's Spiræa and *Spiræa prunifolia* in great profusion. Several species of the *Chimonanthus* or Japan allspice, *Forsythia viridissima*, *Buddlea Lindleyana*, and numerous Daphnes, Gardenias, and Azaleas, were also met with. Many kinds of mosses and Lycopods were growing out of the crevices of the moist rock ; amongst the latter, and very abundant, was a fine species, named *Lycopodium Willdenovii.—Fortune's Tea Districts, page* 57.

(3317) EDGEWORTHIA GARDNERI, is a beautiful shrub, with globes of waxy cowslip-coloured, deliciously scented flowers. This plant is allied to *Daphne*, from whose bark the Nepal paper is manufactured. It was named after the eminent Indian botanist, brother of the late Miss Edgeworth.—*Hooker. Him. Jour. Vol.* 1. *page* 205.

(3318) EDIBLE SEA-WEED. Plocaria Candida. Fucus amylaceus.

Kyouk-pwen, BUR.

A sea weed, abundant on the Tenasserim coast, and exceedingly valuable for its nutritious and medicinal properties for invalids. It was first brought to public notice by Dr. O'Shaughnessy as the Edible moss of the Eastern Archipelago, and referred by him to the genus fucus. The fructifications however being in small tubercles, the Rev., Mr. Mason considers it as a species of Agardhs genus, Sphœrococcus, which now constitutes a member of the genus plocaria. It is an allied genus with the Ceylon moss (Gigartina lichenoides) first described as fucus amylaceus by Dr. O'Shaughnessy, the Plocaria lichenoides of Mr. Mason ; also with a species found on the coast of Devonshire in England ; Pl. compressa : with the Corsican moss of the Mediterranean, P. Helminthochorton : also with the Agar-agar Pl : tenax : but differs from the Irish moss or Chondrus crispus : and is not of the same natural family as the Iceland moss which, indeed, is a lichen, the Cetraria islandica. The Tenasserim moss is said to be superior to all others, as it is wholly free from the bitter principle which renders other fuci so objectionable ; but Mr. Mason seems to consider it almost identical with the Ceylon moss, for he gives the same account of it as Dr. O'Shaughnessy gives of that from Ceylon. It contains he says a considerable proportion of starch, and was hence named by Dr. O'Shaughnessy, the starch fucus, Familaceus, but his specific name has been since changed to *candida*, white, probably from a mistaken idea that the substance is naturally white, whereas it becomes so only by bleaching in the sun ; its natural tint, is a shade between olive and purple, such as the natives designate red. Burmese Kyouk-pwen. According to Dr. O'Shaughnessy's analysis it contains as follows :

Vegetable jelly,.....	54 5
True starch,.....	15.0
Wax, a trace,.....	0.5 ?
Ligneous fibre,.....	18.0
Gum,.....	4.0
Sulphate and muriate of soda,.....	6.5
Sulphate and phosphate of lime,.....	1.0
Iron, a trace,.....	0.4 ?
	100.0

On the best mode of preparing it for use he adds : " In the first place, from the tendency of *pectin* or vegetable jelly to form insoluble compounds with saline and earthy bases, it is necessary to steep this fucus for a few hours in *cold rain water* as the first step in its preparation. This removes a large portion, if not the entire, of the sulphate of soda, leaving all the gelatine, and starch. It should next be dried by the sun's rays, and *ground to a fine powder* ; I say *ground*, for cutting or pounding, however diligently or minutely performed. still leaves the amylaceous globules so mechanically protected, and so closely involved in an external sheath of tough ligneous fibre, that scarcely a particle of the starch can be extracted by boiling, even though the decoction is prolonged for several hours. When *ground*, boiling for 25 minutes or half an hour dissolves all the starch and gelatine. The solution while hot should be passed through muslin or calico, and thus the ligneous fibre is removed : lastly, the strained fluid should be boiled down till a drop placed on a cold surface gelatinizes sufficiently. " With milk and sugar, and flavoured with lemon juice or sherry, this substance, when prepared as I direct, would afford the invalid a pleasant article of diet, especially at sea, where other jellies or their materials cannot be so easily preserved. As I am informed that this fucus is found abundantly on the eastern coast of Bengal, I entertain considerable

hopes of its being hereafter found available also in several processes of art and various manufactures."—*Mason.*

(3319) EDDOES, the name by which the esculent *Caladium* is known by the blacks of the Gold Coast.

(3320) EEE-GYWOT-SHA, a bast of Arracan, strips five to six feet in length, composed of several layers, of which one side is smooth and compact, and the layers on the other side thin but cancellar: all having a considerable degree of toughness.

(3321) EERPILAKAI, Tam. ARTOCARPUS PUBESCENS. Wild.

Angelie marum kai, Tam.

This fruit somewhat resembles the Datura and is the produce of the tree called by Rheede Ansjeli (See Hort Mat. Part 3d table 32d), who tells us that when eaten much it is apt to produce diarrhœa which however is cured by the root and bark of the same tree.—*Ainslie, p.* 240.

(3322) EGERIA, a genus of Brachyurous Decapod Crustaceans established by Leach, and thus characterised:—External antennæ short, inserted on the sides of the rostrum, having their second joint much shorter than the first. External jaw-feet having their third articulation straight on the internal border, and terminated by a point. Claws delicate, linear, double the length of the body in the males, nearly equalling it in the females, much shorter in both sexes than the rest of the feet, which are very slender, those of the fifth pair being five times the length of the body. Carapace triangular, tuberculated, and spinous, terminated by a rather short rostrum, which is bifid, with diverging points. Eyes much larger than their peduncle. Orbits having a double fissure on their superior border. *E. Indica*, in size, general form of the body, and length of the feet, bears a great resemblance to *Inachus Scorpio*; but besides generic differences, it is still further removed from it in having a larger rostrum, which is deeper incised in the middle, and in having the points with which the elevated and distinct regions of the carapace above are beset disposed in the following order: 3, 2, 1 and 1. A rather long sharp post-ocular point is directed forwards. The arms are rather short and slender. It inhabits the Indian seas. —*Eng. Cyc.*

(3323) EGRET, the common name of several species of Heron. In Australia, what in India we call 'White Paddy-birds,' and in Britain are the much prized Egrets, have come to be denominated 'Cranes;' and the real Crane of that country is known as the 'Native Companion.'

(3324) EGYPTIAN BEAN, a name sometimes given to the bean-like fruits of *Nelumbium speciosum*, from the notion that they were the beans which the disciples of Pythagoras were forbidden to eat.

(3325) EHRETIACEÆ, *Ehretiads*, a small natural order of Exogenous Plants, consisting of shrubs or trees inhabiting the warmer countries of the world, and having rough leaves, monopetalous regular flowers, a definite number of stamens, a superior ovary, a 2-lobed style whose divisions are capitate, and a nucamentaceous undivided fruit. The flowers are more or less gyrate, and the order itself, which contains no species of economical value, is so near *Boraginaceæ* as to render it doubtful whether it ought to be separated. The common Heliotrope is the most generally known representative of *Ehretiaceæ*, forming however the type of a sectional division characterised by the fruit being dry, not succulent. There are 14 genera and 297 species of this order. Wight gives Ehretia aspera, 1383-84; (X.) cuneata, 1385; lævis, 1382; ovalifolia, 1383; umbellulata, 1384; viminea, 1385; Wightiana, 1384; The root of *Ehretia buxifolia* is used in medicine, in India. Some of the species of the genus *Ehretia* bear eatable drupes.—*Eng. Cyc.*

(3326) EHRETIA BUXIFOLIA. Roxb.

Visser pullum, Tam.

This fruit I have never seen, but by what I can learn, it is of an inferior order, and is eaten by the poor people.—*Ainslie, p.* 234.

(3327) EHRETIA LÆVIS. Seregada, Tel.

The species grows to a pretty large tree. It is a native of the Circar mountains. The wood of this tree is good and used by the hill people for many purposes. Roxb.—*Rohde M.S.S.*

(3328) EHRETIA OVALIFOLIA.

Naraga marum, Tam.

A common but generally small tree in the Coimbatore district. I am still unacqnainted with the quality of the timber, said to be useless.—*Wight.*

(3329) EGGS, ARTIFICIAL HATCHING OF.—One of the greatest Lions in Chusan is an old Chinaman who every spring hatches thousands of ducks' eggs by artificial heat. His establishment is situated in the valley on the north side of the City of Tinghae, and is much resorted to by the officers of the troops and strangers who visit the island. The first question put to a sight-seer who comes here is, whether he has seen the hatching process, and if he has not, he is always recommended to pay a visit to the old Chinaman and his ducks. The hatching-house was built at the side of the cottage, and was a kind of long shed, with mud walls, and thickly-thatched with straw. Along the ends and down one side of the building are a number of round straw baskets well plastered with mud, to prevent them from taking fire. In the bottom of each basket there is a tile placed, or rather the

tile forms the bottom of the basket; upon this the fire acts,—a small fire-place being below each basket. Upon the top of the basket there is a straw cover, which fits closely, and which is kept shut whilst the process is going on. In the centre of the shed are a number of large shelves placed one above another, upon which the eggs are laid at a certain stage of the process. When the eggs are brought, they are put into the baskets, the fire is lighted below them, and a uniform heat kept up, ranging, as nearly as I could ascertain by some observations which I made with a thermometer, from 95° to 102°, but the Chinamen regulate the heat by their own feelings, and therefore it will of course vary considerably. In four or five days after the eggs have been subject to this temperature, they are taken carefully out, one by one, to a door, in which a number of holes have been bored, nearly the size of the eggs; they are then held against these holes, and the Chinamen look through them and are able to tell whether they are good or not. If good, they are taken back, and replaced in their former quarters; if bad, they are of course excluded. In nine or ten days after this, that is, about fourteen days from the commencement, the eggs are taken from the baskets, and spread out on the shelves. Here no fire heat is applied, but they are covered over with cotton, and a kind of blanket under which they remain about fourteen days more, when the young ducks burst their shells, and the shed teems with life. These shelves are large, and capable of holding many thousands of eggs; and when the hatching takes place, the sight is not a little curious. The natives who rear the young ducks in the surrounding country know exactly the day when they will be ready for removal, and in two days after the shell is burst, the whole of the little creatures are sold, and conveyed to their new quarters. —*Fortune's Wanderings, pages* 76 to 81.

(3330) ELÆAGNACEÆ, *Oleasters*, a small natural order of Apetalous Exogenous Plants, consisting of trees or shrubs whose leaves are either opposite or alternate, destitute of stipules, and always protected more or less by scurfy scales, which usually give the plants a leprous aspect. The genera of this order have a tubular 4-lobed calyx, the inside of which is lined with a fleshy disc, that sometimes almost closes up the tube; there are 3, 4, or 8 stamens, and a superior ovary containing a single erect ovule. The fruit is soft, succulent, and would be eatable if it were not for its dryness and insipidity. In a few cases, when it is more than usually juicy and acidulated, it is actually considered an excellent fruit. *Elaeagnus hortensis* and *E. orientalis* bear a brown fruit about the size of an olive, which is brought to market in Persia under the name of Zinzeyed: in quality it is like a jujube. The red drupes of *E. conferta*, the large olive-shaped ones of *E. arborea*, and the pale orange-colored ones of *E triflora* are in like manner eaten in India; another occurs among the drawings of Chinese fruits. It is not a little curious, nearly as *Elaeagnaceæ* are related to *Thymeleaceæ*, that they do not seem to participate in any degree in the acridity of that deleterious order. The only species found wild in Great Britain is the *Hippophae rhamnoides*, a spiny shrub with diœcious flowers, small round orange-coloured acid berries, and narrow leaves, like those of rosemary, found growing on cliffs near the sea; its fruit, when the acidity is sufficiently covered by sugar, becomes a rather pleasant preserve. *Elaeagnus angustifolia*, called in the gardens the Olivier de Boheme, a native of the eastern parts of Europe, is one of the most fragrant of all plants. Its dull yellow flowers, hardly remarked among the leaves, fill the atmosphere with a delicious perfume, the source of which is not readily discovered by the the passer-by. The genera comprising this order are *Elaeagnus*, *Hippophae*, *Conulemm*, and *Shepherdia*. They embrace about 30 species.—*Eng. Cyc*,

(3331) ELÆAGNUS was common in the Bhooteea country in East Nepaul—*Hooker's Him. Journ., page* 265.

(3332) ELÆAGNUS ANGUSTIFOLIUS E. SINJED, Royle,—is a tree which grows in the mountains as well as in the valley of Cashmere, but medicinally, it is little used by the natives. The ripe berries are eaten by the mountaineers. I administered the leaves and the unripe fruit together. The oil from the seeds with syrup as a linctus has been recommended in catarrhal and bronchial affections.—*Honigberger, page* 273.

(3333) ELÆAGNUS CONFERTA. Hind. Amgoolee. A scandent shrub, with silver coloured leaves beneath. The fruit is red when ripe, and eaten by the natives.—*Riddell.*

(3334) ELÆAGNUS DULCIS. ELAEAGNACEÆ. Hind. Shooshuna. This tree or shrub is usually covered with leprous scales; leaves alternate or opposite, entire, without stipules. Flowers axillary—often fragrant. The fruit is about the size of a small olive, oblong. It is eaten by the Persians.—*Riddell.*

(3335) ELÆOCARPACEÆ, *Eleocarpus*, a natural order of chiefly Indian Trees, having a strong botanical resemblance to our European Lindens, but differing in having fringed petals, and anthers opening by two pores at the apex. In the Indian genera, the nuts, cleared of the soft pulp or flesh that covers them, are curiously sculptured, and being bony and taking a fine polish they are frequently set in gold and strung into necklaces. The nuts of *Ganitrus sphæricus*, a middle-sized tree, common in various parts of India, as well as the Malay Archipelago, and those of *Menocera tuberculata*, from the forests

of Travancore, are what are principally used for this purpose. The fruits of *Elæocarpus serratus*, which are very much like olives when ripe, are said by Roxburgh to be pickled or dried and used in their curries by the natives of India. *E. cyaneus* has pure white, beautifully-fringed petals, and is one of the most ornamental plants of Australia. Lindley, in his 'Vegetable Kingdom,' places this order as a sub-order or division of *Tiliaceæ*.—*Eng. Cyc.*

(3336) ELÆOCARPUS. A hard valuable timber tree is very abundant in the neighbourhood of Rangoon, and not uncommon in some parts of these Provinces, belong to the genus elæocarpus. Carts are sometimes constructed of it, and it is used in house and boat building. —*Mason.*

(3337) ELÆOCARPUS.

Salwen, Burmese.

The river Salwen derives its name from a tree that grows on its banks of that name. I have never seen it, but from the fruit that has been brought to me, I am enabled to state that it is a species of elæocarpus, and from the character of the genus, would probably yield useful wood.—*Mason.*

(3338) ELÆOCARPUS GANITRUS.

Roodrakya, Duk.

This tree is a native of Java, the seeds are about the size of common marbles, and are worn as necklaces by Brahmins and Faqueers, they are commonly called *Utrasum* beads. —*Riddell.*

(3339) ELÆOCARPUS LANCEOLATUS. Bead. Rottl.

Utrasum, Tam. | Ootradge ke munkeh, Duk.

The Utrasum beads, which are very rough, and about the size of small nutmegs are the seeds of the Eliæocarpus lanceolatus. They are brought to India from Java, of which country that tree is a native. The Sheva Brahmins and Pundarums wear them round their heads and necks and also form them into a kind of rosary.—*Ain.'s Mat. Med. page* 142. At Maulmain there is seen this small tree whose handsome summit is whitened over with a profusion of white flowers, it is a species of elæocarpus the genus which furnishes by its tuberculed seed, beads for the Hindoo Fakeers.—*Mason.*

(3340) ELÆOCARPUS OBLONGUS.

Kassow, Duk.

This is a handsome tree, flowers in May, petals beautifully fringed, the foliage is frequently tinged with red, giving an autumnal appearance to the tree.—*Riddell.*

(3341) ELÆOCARPUS TUBERCALATUS.

Roodracha or Badracha, Tam.

This tree is a native of the forests of Travancore, the nuts are worn by the Vishnoo worshipping bramins as rosaries either plain or mounted in gold and silver. Roxb.—*Rohde M.S.S.*

(3342) ELÆODENDRON, (from ἐλαία, an olive, and δένδρον, a tree),a genus of Plants belonging to the natural order *Celastraceæ*. It has a 5-parted calyx; 5 expanding linear-oblong petals; a 5-angled very thick fleshy disc; 5 anthers inserted into the margin of the disc; the filaments at length recurved; anthers with a thick connective, roundish, opening longitudinally; the ovary immersed in the disc, 2-celled; the ovules 2 in each cell; the style short, conical; the stigma simple, obtuse; fruit drupaceous, dry, or pulpy; the nut 1-2-celled; the seeds usually solitary, with a membranaceous or spongy integument erect. The species are small trees with opposite entire glabrous leaves. *E. glaucum* elliptical serrated leaves, hardly three times longer than the petioles; the cymes loose, nearly the length of the leaves; the flowers pentandrous. It is a small tree, about 14 feet in height and is a native of Ceylon and Coromandel. The tree has been introduced into Great Britain from Ceylon under the name of Ceylon-Tea. It has leaves like those of the tea-plant, but it does not appear to be used as a substitute for that plant.

(3343) ELÆODENDRON INTEGRIFOLIA.

Jouk-bin, Burm.

This is a very plentiful, strong, fine timber tree, found throughout the forests of the Tounghoo and Pegu districts, as well as about Rangoon. Wood, white colored, adapted for fancy work and cabinet making.—*McClelland.*

(3344) ELÆODENDRON ROXBURGHII. *Celastrineæ*, Ill. 71. *Syn.* Neerija dichotoma (Roxb, Fl. Ind. i. 646.)

Seloopa marum, Tam.

E. Roxburghii has oblong serrato-crenate, opposite and alternate, hard, smooth, shining leaves, about 4 inches long and 2 inches broad, with the petioles three-quarters of an inch long; the cymes globular, and three times the length of the petioles. It is a native of the mountainous parts of India. It possesses powerful astringent properties, but is not used as an internal medicine.—*Eng. Cyclopædia.* The fresh bark of the root rubbed with plain water is applied by the natives to almost every kind of swelling; it is a very strong astringent, possessing scarcely any other sensible quality. Roxb.—*O'Shaughnessy, page* 271. This tree is more remarkable for its fine form than the length and thickness of its bole, I do not know the wood, but if good, can only be fit for cabinet making and small sized objects.—*Rohde.*

(3345) ELÆIS, a genus of Palms, so named from *Elaia*, the Olive-Tree, because an oil is yielded by the fruit of its principal, if not only species. This is *Elaeis guineensis*, or Oil-Palm, Maba of the natives of the Congo. It is common

all along the western coast of Africa. The tree is monœcious, as we are informed that both male and female spadices were obtained from a single plant cut down by Professor Smith. (Brown, in Tuckey's 'Congo.') The stem is tall, about ten inches in diameter, rough, and bristling with the persistent bases of the petioles, of which the margins, as in recent leaves, are fringed with spines. The leaves are pinnate, about 15 feet in length, with two rows of sword-shaped leaflets, each 18 inches long. The fruit is ovoid, about the size of a pigeon's egg, with its outer fleshy covering of a golden yellow colour; and like that of the section *Cocoinæ*, to which it belongs, and analogous to the cocoa-nut, has the foramina of its putamen at the apex, and not at the base, as represented by Gærtner and others. Mr. Brown has observed it as remarkable that *Cocos indica* and this palm, which is universally, and he believes justly, considered as having been imported into the West India colonies from the west coast of Africa, should be the only two species of an extensive and very natural section of palms that are not confined to America. The *Elæis occidentalis* of Swartz, the Thatch-Tree of Brown's 'Jamaica,' and the Avoira of Aublet, are probably all identical with the Maba, or Oil-Palm, of the African coast. The oil is obtained by bruising the fleshy part of the fruit (and not the kernel as sometimes stated), and subjecting the bruised paste to boiling water in wooden mortars; an oil of an orange-yellow colour separates, which concretes when cool to the consistence of butter, and has when fresh the smell of violets or of the root of Florentine iris, with a very slightly sweetish taste. The oil is used by the Africans in cookery and for anointing the body. It forms a considerable article of commerce to Europe, where it is chiefly employed in perfumery and medicine. *Cocos butyracea* (which is referred by Kunth to the genus *Elæis*) is considered by the Edinburgh College to be the plant which yields palm-oil. Mr. Brown (Tuckey's 'Congo,' Appendix, p. 456) states, "It is probable that *Alfonsia oleifera* of Humboldt, Bonpland, and Kunth belong to *Elæis* and possibly may not even differ from the African species. To this the above authors in the 'Synopsis Plant. Æquinoct.' reply, that in *Elæis*, according to the description of Jacquin, both the floral envelopes are sexifid, while in *Alfonsia* they are trifid. Humboldt and Bonpland found Alfonsia oleifera always growing wild, while Elæis guineensis is never found out of Africa, except in a cultivated state —*Eng. Cyc.*

(3346) ELANET, a form of Hawk (*Falco melanopterus*, Daudin) inhabiting Africa, and also India and America. [FALCONIDÆ.]—*Eng. Cyc.*

(3347) ELATE SYLVESTRIS. PALMACEÆ. Nat. Kajooree. Wild Date. Phoenix Sylvestris.

Eetchum Khulloo. TAM.	Eeinta Khulloo, TEL.
Saundie ka jhar, DUK.	Eajata, CAN.

Wild date toddy.—*Ainslie, Mat. Med. p.* 263.

Eetchum elley, TAM.	Eeintaakoo, TEL.
Sundoolay ka paat, DUK.	

Date tree, wild, stalk and leaf of,

Eatchum pullum, TAM.	Eeinta pundoo, TEL.
Sundooloy ka pull, DUK.	Parooshaka, SANS.

Wild date common throughout the Deccan. Has the general characteristics of the family, but is inferior to the Palmyrah, Cocoanut, &c. This when ripe is a small, oval shaped, dark color fruit. It is sweetish, but is not held in much estimation.—*Ainslie, p.* 224. With the stalks of the Wild Date tree, which are in Tamul called Cassungoo, the Indians make baskets and boxes; with the leaves, hats and coarse baskets are made. In Egypt, it would appear, by Sonnini's account, that baskets are made with the stalks of the Payr Eetchum, or great Date tree, (Phœnix dactylifera): so they are in India, in situations where the Payr Eetchum (Tam.) is found.—*Ains. Mat. Med. p.* 153.

(3348) ELATE, or wild Date. At the Madras Exhibition of 1251 there were only three exhibitors of the leaves of this plant, and these were in a crude unprepared state, or simply split and twisted into rope, its chief uses are for thatching and making light mats, for building huts. The fibres of the leaf stalk are used for cables in the Red Sea. The natives of the East chew the fruit of Elate sylvestris, (which is something like a wild plum) in the same manner as the areca nut, with the leaf of the betel pepper and quick lime. The inner wood furnishes a kind of catechu or Cutch, which contains much tannin and is a powerful astringent. It is obtained by the simple process of boiling the heart of the wood for a few hours, when it assumes the appearance and consistency of tar. It hardens by cooling, and when formed into small squares and dried in the sun is fit for the market. The produce of Bombay is of uniform texture and of a dark red color. That of Concan and other parts of India is of a chocolate color, and marked inside with red streaks.

The analysis of Sir H. Davy gave the following result.

	Bombay.	Concan.
Tannin,.....	54·5	48·5
Extractive,.....	34·0	36·5
Mucilage,.....	6·5	8·0
Insoluble matters, sand, lime &c.	5·0	7·0
	100	100

Simmonds' Commercial Products, page 579.

(3349) ELCAJA, an Arabian Plant, whose fruit is said to possess emetic properties. Botanists call it *Trichilia emetica*. Forskahl describes it as a large tree, with villous shoots, pinnated leaves, with entire oval-oblong pedicellate leaflets, clustered flowers with 5 greenish-yellow petals, 10 monadelphous stamens, and a downy capsular

fruit about an inch long, with 3 valves, 3 angles, and 3 cells, having 2 plano-convex seeds in each cell. The tree is said to be called Roka, and to be common on the mountains of Yemen. The fruit is sold at Beit el fakih, for mixing with fragrant materials with which the Arab women wash their hair. The fruit called 'Djour elkai' is reputed an emetic. The ripe seeds mixed with Sesemum oil are formed into an ointment as a cure for the itch.—*Eng. Cyc.*

(3350) ELECAMPANE.

Ussul ur-rasun, ARAB.	Alantwurzel, GER.
Inuleaulnee, FR.	Beikh-i-zanjabilishami, PERS

Elecampane-root has an aromatic and slightly fetid odour; when chewed, the taste is at first disagreeable, glutinous, and somewhat resembling rancid soap, and then aromatic, bitter and hot. Formerly it used to be prescribed in dyspepsia, pulmonary complaints, and palsy; of late years it is nearly discarded from the *materia medica*.—*Faulkner.*

(3351) ELEMI GUM, of commerce, is said to be yielded by several species of Amyris. It is a resinous substance, which is met with in yellow, tender, transparent masses; it readily softens by the heat of the hand, has a strong aromatic odour, and a hot spicy taste. It is used in making lacquer to give toughness to the varnish —*Waterston. Faulkner.*

(3352) ELEMI, American, comes from Icica icicariba, and the Resin of Courina from I. ambrosica.

(3353) ELEOTRIS, a genus of Acanthopterygious Fishes belonging to the family *Gobiodæ*. Like the Gobies the species have flexible spines in the first dorsal fin, and an appendage behind the vent, but they have the ventral fins separate and six gill-rays. The species are inhabitants of the fresh waters of warm countries, and conceal themselves in the mud. *E. dormatrix*, the Sleeper, is a large fish. It is found in the West Indian marshes. Other species have been found in Africa, India, and the Mediterranean.

(3354) ELEPHANT.

Elephas and Elephantus, LAT.	Elephant, GER.
	Olyphant, DUT.
Ἐλέφας, GREEK.	Hathee, HIND.
Elephante, SP.	Fel, PERS.
Elephantes, IT.	Ani, TAM.
Elephant, FR.	Yeni, TEL.

The name of the well-known genus which forms the only living type of the family of true Proboscidians, or Pachydermatous Mammilifers with a Proboscis and Tusks. It is the largest of existing terrestrial animals. There are two living species of the genus, the African and Indian.—*E. Indicus*, the Asiatic Elephant, differs from the African species, not only in its greater size and in the characters of the teeth and skull, but also in the comparative smallness of the ears, the paler brown colour of the skin, and in having four nails on the hind feet instead of three. The sagacity of this species is also supposed to be greater than that of the African Elephant. But though many wonderful stories are told, and some of them are as true as they are wonderful, of the grateful remembrance which it long retains of benefits conferred, or of the tenacity with which it "treasures up a wrong," and though the instances of its docility, both ancient and modern, are very extraordinary, we agree upon the whole with Baron Cuvier, who observes, that after having studied these animals a long time, he never found their intelligence surpass that of a dog nor of many other carnivorous animals. It is imposing to see such a mountain of vitality obedient to the voice of its keeper, and performing feats at his dictation; and the massive gravity of its physiognomy assists the impression. The following is Mr. Corse's description of a perfect Asiatic Elephant:—An elephant is said to be perfect when his ears are large and rounded, not ragged or indented at the margin; his eyes of a dark hazel-colour, free from specks; the roof of his mouth and his tongue without dark or black spots of any considerable size; his trunk large, and his tail long, with a tuft of hair reaching nearly to the ground. There must be five nails on each of his fore feet, and four on each of the hind ones, making eighteen in all; his head well set on, and carried rather high; the arch or curve of his back rising gradually from the shoulder to the middle, and thence descending to the insertion of the tail, and all his joints firm and strong. The following are the castes (Zat) or varieties of the Asiatic Elephant noticed by Mr. Corse. Both males and females are divided into two castes by the natives of Bengal, namely, the Koomareah (of a princely race) and the Merghee (hunting elephant, from 'mrigah,' a deer, or hunting, or from its slender make), and this without any regard to the appearance, shape, or size of the tusks in the male, as these serve merely to characterise some varieties in the species. The Koomareah is deep-bodied, strong, and compact, with a large trunk and short but thick legs. The Merghee is generally taller but is not so compact nor so strong: he travels faster, has a lighter body, and his trunk is both short and slender, in proportion to his height. As a large trunk is considered a great beauty in an elephant, the Koomareah, is preferred, not only for this, but for its superior strength, and greater capability of sustaining fatigue. The mixed breed is held in greater or less estimation in proportion as it partakes of the qualities of the Koomareah or Merghee. A breed from a pure Koomareah and Merghee is termed Sunkareah (from 'sunkarah,' a mixture,) or Merghabauliah (for the most part Merghee); but a farther mixture or crossing of the breed renders it extremely difficult for the hunters to ascertain the variety. Besides the K-

marcah, Merghee, and Sunkareah breeds, several varieties are generally to be found in the same herd; but the nearer an elephant approaches to the true Koomareah the more he is preferred, especially by the natives, and the higher will be his price; though Europeans are not so particular, and will sometimes prefer a female Merghee for hunting and riding, when she has good paces, and is mild and tractable. The variety of male termed Dauntelah (toothy, having large fine teeth,) produces the largest tusks and the finest ivory; his head is strongly contrasted with that of the Mooknah (probably from 'mookh,' the mouth or face), which can hardly be distinguished in this respect from a female elephant; and the tusks of some of the females are so small as not to appear beyond the lip, while in others they are almost as large as in the variety of male called Mooknah. The Dauntelah is generally more daring and less manageable than the Mooknah; and for this reason, until the temper and disposition are ascertained, the Europeans prefer the Mooknah; but the natives, who are fond of show, generally take their chance, and prefer the Dauntelah: and though there is a material difference in their appearance as well as in the value of their tusks, yet, if they are of the same caste, size, and disposition, and perfect, there is scarcely any difference in their price. There are many varieties between the Mooknah and Dauntelah, and these are varied according to the variation of the form of the tusks, from the projecting horizontal but rather elevated curve of the Pullung-Daunt of the true Dauntelah, to the nearly straight tusks of the Mooknah, which point directly downwards. 'Pullung' signifies a bed or cot, and 'daunt' teeth; and, from the tusks projecting so regularly, and being a little curved and elevated at the extremities, the natives suppose a man might lie on them at his ease, as on a bed. (Corse.) Thus the Goneish or Ganesa, which is a Dauntelah that has never had but one tusk and this of the Pullung sort, and which is so called from Ganesa, the Hindoo god of wisdom, who is represented with a head like an elephant's with only one tooth, was sold in Mr. Corse's time to the Hindoo princes for a very high price, to be kept in state and worshipped as a divinity. Another variety of the Dauntelah has the large tusks pointing downwards and projecting only a little beyond the trunk: he is then said to have Soor or Choor-Daunt (Hog's teeth). A third is the Puttel-Dauntee, whose tusks are straight like those of the Mooknah, only much longer and thicker. The Ankoos-Dauntee is a fourth, and has one tusk growing nearly horizontal, like the Pullung-Daunt, and the other like the Puttel-Daunt, and there or other less distinct varieties. The term Goondah seems to be used to designate those wandering male elephants which are much larger and stronger than the male generally taken with the herd, the Goondah departing from it or returning to it according to its desire. The Goondahs are supposed to be rarely taken with the herd: when they are so taken, their violence and ferocity render them most destructive. Mr. Corse relates an instance of the ungovernable passions and terrible havoc occasioned by the savage disposition of one, or at least a large male that was supposed to be one, when in the Keddah which is the name of the inclosure into which the wild elephants are driven and then captured. He was at length tied and led out, but his untameable spirit could not brook restraint, and after languishing about forty days he died. Mr. Hodgson, in his paper 'On the Mammalia of Nepaul' ('Zool. Proc,' 1834, suggests that there are two varieties, or perhaps rather species of the Indian Elephant, *Elephas indicus*, namely, the Ceylonese, and that of the Saul Forest. The Ceylonese has a smaller and lighter head, which is carried more elevated; it has also higher fore quarters. The elephant of the Saul Forest has sometimes nails on its hinder feet. The height to which the Asiatic Elephant will attain has been variously stated: but upon a strict examination of alleged great heights, the natural disposition among men to exaggerate has generally been detected. A male elephant recorded by Mr. Corse was at its birth 35 inches high.

In one year he grew	11	inches,	and was	3	feet	10	inches high.
In the 2d year	8	"	"	4	"	6	"	"
In the 3rd year	6	"	"	5	"	0	"	"
In the 4th year	5	"	"	5	"	5	"	"
In the 5th year	5	"	"	5	"	10	"	"
In the 6th year	3½	"	"	6	"	1¼	"	"
In the 7th year	2¾	"	"	6	"	4	"	"

A female Elephant was 6 feet 9 inches high at the time she came into Mr. Corse's possession, and was supposed to be 14 years old according to the hunters; but, according to the belief of Mr. Corse, she was only 11 years of age. During the next 5 years, before she was covered, she grew only six inches, but, while, pregnant, she grew 5 inches in 21 months, and in the following 17 months, though again pregnant, she grew only half an inch. Mr. Corse then lost sight of her. She was at this time about 19 years old, and had perhaps attained her full growth. Her young one was then not 20 months old, yet he was 4 feet 5½ inches high, having grown 18 inches since his birth. It thus appears that no certain standard of growth, for captive elephants at least, can be depended on; nor do there seem to be any satisfactory data for defining the age at which the animal ceases to grow. Mr. Corse conjectures that elephants attain their full growth between the ages of 18 and 24. With regard to the height, the East India Company's standard for serviceable elephants was, in Mr. Corse's time, 7 feet and upwards, measured at the shoulder in the same manner as horses are. At the middle of the back they are considerably higher; and the curve or arch, particularly in young elephants, makes a difference of several inches. The

lessening of this curve is a sign of old age when not brought on by disease or violence. During the war with Tippoo Sultaun, of the 150 elephants under the management of Captain Sandys, not one was 10 feet high, and only a few males 9½ feet high. Mr. Corse was very particular in ascertaining the height of the elephants employed at Madras, and with the army under Marquis Cornwallis, where there were both Ceylon and Bengal elephants, and he was assured that those of Ceylon were neither higher nor superior, in any respect, to those of Bengal: nay, some officers asserted that they were considerably inferior in point of utility. The only elephant ever heard of by Mr. Corse as exceeding 10 feet, on good authority, was a male belonging to Asaph ul Dowlah, formerly vizier of Oude. The following were his dimensions:—

	Feet.	Inches.
From foot to foot over the shoulder,.....	22	10½
From the top of the shoulder, perpendicular height,.....	10	6
From the top of the head when set up as he ought to march in state, ...	12	2
From the front to the face of the insertion of the tail,.....	15	11

And yet the Madras elephants have been said to be from 17 to 20 feet high. Now let us see how dimensions shrink before the severity of measurement. Mr. Corse heard from several gentlemen who had been at Dacca, that the Nabob there had an elephant about 14 feet high. Mr. Corse was desirous to measure him, especially as he had seen the elephant often at a former period, and then supposed him to be 12 feet high. He accordingly went to Dacca. At first he sent for the mahote, or driver, who without hesitation assured him that the elephant was from 10 to 12 cubits, that is, from 15 to 18 feet high; but added that he could not bring the elephant for Mr. Corse's examination without the Nabob's permission. Permission was asked and granted. Mr. Corse measured the elephant exactly, and was rather surprised to find that the animal did not exceed 10 feet in height. The elephant is subject to albinism, and the white elephants so much esteemed by the Indian sovereigns are merely Albinos. The Asiatic Elephant inhabits the greater part of the warm countries of Asia, and the large islands of the Indian Archipelago. Mr. Corse states that the elephants for the service of the East India Company are generally taken in the provinces of Chittagong and Tiperah; but from what he had heard, those to the southward of Chittagong, in the Burmah territories and kingdom of Pegu, are of a superior breed. In confirmation of this opinion, he observes that the elephants taken to the south of the Goomty River, which divides the province of Tiperah from the east to west, were generally better than those taken to the north of that river; and though elephants were taken at Pilibet as far north as 29° N. lat. in the vizier of Oude's territories, yet the vizier, and also the officers of his court, gave those taken in Chittagong and Tiperah a decided preference, they being much larger and stronger than the Pilibet elephant. Till the year 1790 Tiperah was a part of the Chittagong province; and so sensible was the Bengal government of the superiority of the southern elephants for carrying burdens, enduring fatigue, and being less liable to casualties, that in the then late contracts for supplying the army, the contractor was bound not to send any elephant to the military stations taken north of the Chittagong province. Hence Mr. Corse concludes the torrid zone to be the natural clime, and the most favourable for producing the largest, the best, and the hardiest elephant; and that when this animal migrates beyond the tropics the species degenerates. He speaks of the elephants taken on the coast of Malabar as far north as the territories of the Coorgh Raja; as much inferior to the Ceylon elephant, and that from this circumstance the report of the superiority of the Ceylon elephant to all others probably originated. He remarks that most of the previous accounts respecting the Asiatic Elephant had been given by gentlemen who resided many years ago on the coast of Malabar or Coromandel, where, at that time, they had but few opportunities of seeing the Chittagong or the Pegu elephant. Mr. Hodgson, in the paper above noticed, states that *Elephas indicus* and *Rhinoceros unicornis* are both abundant in the forests and hills of the lower region of Nepaul, whence, in the rainy season, they issue into the cultivated parts of the Tarai to feed upon the rice crops. In a state of nature the Asiatic Elephant lives in great herds, which are generally said to be under the conduct of the old males, or bulls, as they are sometimes termed. From time immemorial the species has been brought under the dominion of man, and trained to swell the pomp of pageants, and add to the terrors of war, as well as to perform the more useful offices of a beast of burden and draught, and the more dreadful one of executing the sentence of death on criminals. It has been long made the companion of the sports of the orientalist in the great hunting parties; and from the same early period has been made to minister to the wanton and cruel pleasures of Eastern princes, by being stimulated to combat not only with other elephants but with various wild animals. The reader will find in the second volume of the 'Menageries' in the 'Library of Entertaining Knowledge,' an abundant and amusing collection of anecdotes connected with this subject, as well as a complete History of the Elephant both in the wild state and as the servant of man. The tusks of both species still form, as they did from the earliest periods, a valuable article of commerce. The ivory, which is now sought for useful purposes and ornaments of minor importance, was in great request with the ancient Greeks and Romans for various domestic uses, as well

as for the chrys-elephantine statuary rendered so famous by Phidias. Of these rich statues the Minerva of the Parthenon, and especially the Olympian Jupiter, appear to have been the masterpieces.—*Eng. Cyc.* Within the forests and in the jungles of Ceylon are found a great variety of wild animals—the elephant, the hyena, tiger-cat, the bear, the deer and the monkey, are among the most abundant. The number of elephants is incredibly great, and, issuing in troops from their lairs, they come crushing down the cultivated fields and plantations and devouring the crops, with great loss to the proprietors. They are found in all the uncultivated parts of the island but their favorite haunts are near to the farms, to which they prove so destructive that the colonial government pays a reward of 7s. 6d. (about 1 Dollar, 85 cents) for every tail of the animal which is brought to the authorities. Mr. Talbot the Government agent at Galle, stated, surprising as it may seem, that he had paid during the preceding year two hundred pounds sterling for tails, which would give six hundred as the number of elephants destroyed. An army officer, as was stated to the Commodore, actually killed during his residence on the island, no less than six hundred of these gigantic animals. Within a few months of the arrival of the Mississippi, two officers of the garrison one of whom (Lieutenant Lennox) became personally known to the Commodore, destroyed no less than forty elephants in the course of a sporting visit of six weeks to the jungle. They are ordinarily shot with a rifle, the sportsman approaches his game in front, or perhaps, as the sailors would say, on the quarter that he may aim at either of the only two vital parts upon which a rifle ball will have any effect, one being directly in the forehead through which the brain is penetrated and the other behind the ear. If the hunter chance to come up to his elephant in the rear, he raises a shout or makes a noise, by which the animal is attracted and turning its head, or throwing forward its ears exposes the vital spot, at which its ruthless enemy aims the deadly ball, and brings down his huge victim. The elephants of Ceylon are not so large as those of other parts of India, and but a small proportion of them have tusks.—*American Expedition to Japan, p.* 143. Amongst the remarkable remains brought from the Sewalik Hills, in Hindustan, by Captain Cautley and Dr. Falconer are the remains of several species of the genus *Elephas* and other proboscidean animals. Dr. Falconer, speaking of the group of animals thus revealed by his researches, says;—"this fossil Fauna is composed of representative types of *Mammalia* of all geological ages, from the oldest of the tertiary periods down to the most modern; and of all the geographical divisions of the old continent, grouped together into one comprehensive assemblage. Among the forms contained in it there are—of the *Pachydermata* several species of *Mastodon*, Elephant, Hippopotamus, Rhinoceros, *Anoplotherium*, and three species of *Equus*; of the *Ruminantia* the colossal genus *Sivatherium*, which is peculiar to India, with species of *Camelus*, *Bos*, *Cervus*, and *Antilope*; of the *Carnivora*, species of most of the great types, together with several undescribed genera; of the *Rodentia* and *Quadrumana* several species; of the *Reptilia*, a gigantic tortoise (*Colossochelys*), with species of *Emys* and *Trionyx*, and several forms of Gavials and Crocodiles. To these may be added the remains of Struthiones and other birds, and Fishes, *Crustacea*, and *Mollusca*."

The genus *Elephas* in the collection which has been deposited in the British Museum includes six species.

E. planifrons, distinguished by the flatness of the forehead and the intermediate character of its molar teeth.

E. Namadicus, with a great development of the cranium, and teeth closely allied to those of the Indian species.

E. Hysudricus, with a turban-like vortex of the skull and teeth, whose structure approaches that of the African Elephant.

E. Ganesa is the most remarkable of the Sewalik species. A skull exists with remains of the other species in the British Museum. The total length of the cranium and tusks is 14 feet; length of the skull 4 feet 2 inches; width of the muzzle 2 feet; length of the tusks 10 feet; circumference of the tusk at the base 26 inches. The other two species are named *E. insignis* and *E. bombifrons*. The species of *Mastodon*, in the collection from the Sewalik Hills, are *M. Perimensis*, *M. Sivalensis*, and *M. latidens*. Professor Owen states that a species of *Mastodon*, nearly allied to *M. angustidens*, has left its remains in the ossiferous caves and post-tertiary or newer tertiary deposits of Australia. From the conformity of the molar teeth Cuvier regarded a *Mastodon* whose remains have been discovered in Peru as identical in species with the *M. Angustidens* of Europe. Professor Owen regards the *M. longirostris* of Kaup, found in Germany, and the *M. Arvernensis of* Croizet and Jobert, dug up in Auvergne, as identical with his *M. angustidens*. In the collection of the British Museum, in addition to the species which we have mentioned above, will be found remains of *Elephas priscus* and *E. meridionalis*, found in Europe. There is also the remains of a species of *Mastodon*, *M. Andium*, from Buenos Ayres. (Owen, *British Fossil Mammals and Birds*; Falconer and Cautley, *Fauna Antiqua Sivalensis*; Mantell, *Petrefactions and their Teachings.*)—*Eng. Cyc. pages* 504 *to* 519.

(3355) ELEPHANT'S TAIL, HAIR OF.

ıay val myre, TAM. | Yeanugha toka ventroocaloo,
ateeke doom ke bal, DUK. | TEL.

Of this article, rings, bracelets and other female ornaments, are made in India.—*Ains. Met. Ind. page* 154.

(3356) ELEPHANT'S TEETH. These are obtained in South Africa, Ceylon, Burmah, &c. Much of that which comes to China is brought from Siam in junks; the northern parts of Siam, Cambodia, and the confines of Burmah supply that market. A good deal finds its way into China direct from Burmah. They should be chosen without flaws, solid, straight, and white; for if cracked or broken at the point, or decayed inside, they are less valuable; every specimen, however, is useful to a greater or less degree, and can be entirely used. The largest and best weigh from 5 to 8 to a pecul, and decrease in size to 25 in a pecul. The cuttings and fragments are also of value sufficient to make them an article of trade. The number of articles which the Chinese make of it, and the demand for them on account of their exquisite workmanship, render the consumption very great. The circular balls which the Chinese make of ivory, as was well as their miniature boats, fans, chessmen, boxes, and fancy articles of all descriptions, are specimens of carved work unequalled in any other part of the world. From a quantity of ivory not weighing over three pounds, they will make a toy worth a hundred dollars. The largest teeth are sometimes valued at $120 a pecul, but the article usually ranges from $50 to $80 per pecul. This trade is likely to increase at the north. A large proportion of the ivory brought to China is re-exported in fancy carved ware.—*Morrison.*

(3357) ELEPHANTOPUS from ἐλέφας, an elephant, and πούς, a foot, on account of the shape of its radical leaves), a genus of plants belonging to the natural order *Compositae*, the sub-order *Corymbiferae*, the tribe *Vernoniaceae*, the sub-tribe *Vernonieae*, and the division *Elephantopeae*. It has heads containing 3-4-5 florets, closely collected into a cluster, surrounded by leaves; the involucre compressed in two rows, the leaflets dry, oblong, alternately flat and folded, the inner usually 3-nerved; the receptacle naked; the corolla palmate, with a 5-cleft limb, which has acuminate segments and one recess deeper than the others; the filaments smooth, the branches of the style half subulate; the achenium rather compressed, many ribbed, oblong, hairy; the pappus in one row consisting of several straight paleæ, dilated at the base, but otherwise very narrow, acuminate, equal, and serrated. *E. scaber* has a hairy dichotomous stem, the radical leaves scabrous, cuneate, and very much narrowed at the base, those of the stem lanceolate. This plant is common in almost all parts of India, in dry elevated positions. It has a stem a foot high, with the heads of pale-red flowers on long stalks. The roots are fibrous. Both the roots and the leaves are reputed to have active medical properties. The natives on the Malabar coast use a decoction of them in cases of dysuria. There are other species natives of South America and the West Indies. (Lindley, *Flora Medica;* Loudon, *Eng. Cyclopædia of plants.*—*Eng. Cyc.*

(3358) ELETTARIA, a genus of Plants belonging to the natural order *Zingiberaceæ*. The characters of this genus are the same as *Amomum*, but the tube of the corolla is filiform and the anther naked. *E. Cardamomum*, True Cardamom, is a native of the mountainous districts of the coast of Malabar, especially above Calicut, in the Wynaad district, between 11° and 12° N. lat., where the best are produced. Cardamoms formed a portion of the early commerce, which subsisted between this part of India and Arabia, whence they must have been made known to the Greeks, as they are described by Dioscorides, and mentioned as early as the time of Hippocrates. The Cardamom plant delights in moist and shady places on the declivities of the hills. It is cultivated from partings of the root in the districts of Soonda Balaghaut, but the fruit is very inferior; the best grows in a wild state, at least where no other measures are adopted than clearing away the weeds from under the largest trees, which are felled close to the roots. The earth being loosened by the force of the fallen tree, young Cardamom plants shoot forth in a month's time, and are sheltered by the shade of the branches. The tree-like herbaceous plants attain a height of from 9 to 13 feet. The root is as tortuous and tuberous as that of the ginger, and the leaves, with long sheathing foot-stalks, are from one to two feet in length, placed in two rows, and lanceolate in shape, like those of the Indian Shot (*Canna indica*) common in English gardens. The scapes, or flower and fruit-bearing stalks, make their appearance in February of the fourth year, from the base of the stems, are three to four in number, and from one to two feet long, lax, and resting on the ground. The fruit is ripe in November, and requires nothing but drying in the sun to be fit for commerce. The seeds are gratefully aromatic and pungent with a flavour of camphor, and are regarded as a necessary article of diet by the inhabitants of Asia. They are used in medicine, and enter into a number of pharmaceutical preparations.—*Eng. Cyc.*

(3359) ELETTARIA CARDAMOMUM. True, or Malabar, or lesser cardamom. *Syn.* Alpinia Cardamomum. *Roscoe*, and *Roxb. Fl. Ind.* i. 70. *Vern.* Chotee-elachee, and Guzeratee-elachee, *Hind.* A native of the mountains of Malabar and Canara.—*O'Shaughnessy, page* 651. Plantations are in the North-East districts of Travancore. The cardamoms are collected in November and December. They are only of the

government monopoly, as the cultivators chiefly come from Madura and Dindigul and receive about two hundred Rs. for each candy delivered to the sircar. The average annual produce is 300 candies.—*M. E. of* 1857.

(3360) ELETTARIA CARDAMOMUM MEDIUM. *Syn.* Alpinia card. med. *Roxb.* i. 74. Dokeswa of Sylhet. Burra-elachee, *Hind.* Lindley supposes this to be the *Cardamomum medium* of writers on pharmacy. Pereira considers it likely that the *wild cardamoms* of Calcutta are identical with these fruits. One hundred parts of the fruit yielded 70 of seeds and 30 of tunics. One pound gives four scruples of volatile oil, of whitish colour, and thick consistence. *O'Shaughnessy, p.* 651.

(3361) ELETTARIA CARDAMOMUM ZEYLANICUM. Pereira. The produce of Quilon and Matura, the fruits are analogous to the Malabar cardamon in all their properties.—*O'Shaughnessy, page* 651.

(3362) ELEUSINE, a genus of Plants belonging to the natural order of the Grasses. *E. coracana* is cultivated as a corn-plant by the inhabitants of the Coromandel Coast, and is known by the name of Natchnee. According to Schomburg a decoction of another species, *E. Indica*, is employed in Demerara in the convulsions of infants. *E. Tocusso* is an Abyssinian corn-plant belonging to this genus.—*Eng. Cyc.*

(3363) ELEUSINE CORACANA, CYNOSURUS CORACANUS, Lin.

Kaywur, TAM.	Munrivee, HINDOOEE.
Raggi, DUK. and CAN.	Tsjetti pullu, HORT. MAL.
Tamidaloo, TEL.	Natchenny Rajika, SANS.
Moatauny, MAL.	Cynosurus Coracanus. LIN.

This very useful grain is called, in Tinnevelly Capa, and, in some parts of the higher provinces of Hindoostan, Murha and Maud. It is much eaten by the common people.—*Ainslie, p.* 219. *Eleusine* (*Cynosurus*) *coracana.*—Ragi (Canarese), kevaru (Tamil), is extensively grown by the Ryots, and is the staple food of the inhabitants of Mysore; and though coarse in appearance, is a wholesome and nutritious grain. It possesses also the very valuable quality of being very indestructable; and may be preserved for about sixty years if carefully deposited in grain caves or pits. These pits are generally placed in hard dry ground. The pit is formed by digging a small hole of the size to admit a man, and as the hole descends, it is enlarged into a moderate sized circular room. After the pit is dug out, a large fire is lit in it to harden the sides. These stores of Ragi are of inestimable value in moderating dearths, as the grain remains sound for very many years. Ragi straw is a very good fodder for cattle, and it too keeps well. Owing to failure of rain, Ragi may be high priced in Mysore; but there is no scarcity of that grain, large stocks of it being kept in the granaries of wealthy farmers. Ragi is exported in large quantities, to Neilgherries, Salem, Bellary, Chittore, Madras, Trichinopoly, &c. When cheap, Ragi sells in Bangalore at seven Marcals or eighty-four seers for a Rupee; or if dear, 2½ Marcals or thirty Seers. Ragi is usually sown in fields mixed with *Buller, Togari, Hutchellu, Iave, kari Jola, Sasara*, and *Haralu;* and the sowing Machine, which is, a kind of drill, consists of many reeds with holes, so that the whole of the seeds are sown through their respective holes in parallel lines. The principal supply of Ragi is grown in the Bangalore and Ashtagram Divisions, the other two Divisions from local causes producing scarcely enough for their own consumption.—*Madras Exhibition of* 1857. A fermented liquor is prepared from it called Bojah, chiefly drunk in the Mahratta countries.—*Ainslie, page* 219. MURWA, The intoxicating drink prepared from Ragi, is used in the Sikkim Himalaya, and seems more to excite than to debauch the mind. It is made from partially fermented Murwa grain (*Eleusine coracana.*) *Hooker, Him: Jour: Vol:* I. *p:* 133. The millet seed is moistened, and allowed to ferment for two days. Sufficient for a day's allowance is then put into a vessel of wicker work, lined with India Rubber to make it water tight, and boiling water is poured on it with a ladle of gourd, from a large iron cauldron that stands all day over the fire. This fluid when quite fresh tastes like negus of Cape Sherry, rather sour.—*Hooker, Him. Jour. Vol.* I. *page*, 291.

(3364) ELEUSINE INDICA. Tufts of eleusine are conspicuous every where among other grasses of Tenasserim.—*Mason.*

(3365) ELOOPEI POO, TAM.

Mohe ka pool, DUK.	Madooka, SANS.
Ippa poo, TEL.	

Flower of the long leaved bassia—Bassia longifolia Lin. These singular looking sweet flowers are collected in great quantities in some parts of the Circars as well as in Bahar, and after having been dried in the sun, are sent all over the Maharatta countries like dried grapes, in Europe, which they somewhat resemble in taste. The Reverend Doctor John of Tranquebar in an account of the same flowers, which may be found in the 8th Volume of the Asiatic Researches, informs us, that, after being bruised and boiled to jelly, the Natives form them into balls, which they exchange for fish and rice. At Chatra in Ramgur and in some other provinces of upper India, a spirituous liquor (2) is distilled from the flowers, which are there called Mahwah flowers and there is also in some districts of lower Hindostan, a spirituous liquor distilled from the flowers of another species of the same tree, called in Tamul Caat Eloopei, (Bassia latifolia). The fruit of it is a drupe, egg-shaped and

pointed, containing from three to five seeds.—*Ains. Mat. Med. page* 259.

(3366) EMBELIA PETRANDRA, Myrsinaceæ.

Ambut, Duk.

A scandent shrub with alternate polished leaves; flowers in the cold season: fruit red, size of a currant.—*Riddell.*

(3367) EMBELIA RIBES.—Another of the species; a scandent shrub like the former, only with rough tuberous knobs on the stem; both are confined to the higher ranges of mountains.—*Riddell.*

(3368) EMBLICA, a genus of Plants belonging to the natural order *Euphorbiaceæ.* It has monœcious flowers; the calyx 6-parted; 5 stamens combined; 3 styles dichotomous; the fruit fleshy, tricoccous, 6-seeded.—*Eng. Cyc.*

(3369) EMBLICA OFFICINALIS, Gaertner. Syn. Phyllanthus Emblica, *Linn.* Μυραβαλανος εμβλικα. Arctuar, 1. 24 Nilicamaram, *Rheede.*

Tree crooked, thick as a man's body, leaves pinnate, flower bearing, flowers minute, greenish yellow. *E. officinalis* a tree having a crooked trunk, with branches thinly scattered in every direction; the male branches spreading and drooping. The leaves are alternate, spreading, one or two feet long, and about one and a half or two inches broad: the stipules small, withering; the flowers minute, of a greenish colour: the fruit a drupe, fleshy, globular, smooth, 6-straited: the nut obovate, obtusely triangular, 3-celled; the seeds two in each cell. The bark of this tree is astringent, and is used in India as a remedy for diarrhœa. The fruit is acid, and tastes astringent, and when eaten acts as a mild purgative. This plant is the *Phyllanthus emblica* of Linnæus; and *Myrobalanus emblica* of Bauhin (Lindley, *Flora Medica.*)—*Eng. Cyc.* This tree is found cultivated in most parts of India and also wild in forests, It flowers during the beginning of the hot season, and its fruit ripens in eight or nine months after. The wood of this tree is hard and durable, particularly under water. The bark is strongly astringent; the natives employ it to cure diarrhœas and to tan leather. The fruit is at all times full of exceedingly sharp juice, it is eaten raw by the Natives although to an European the taste is disagreeably acrid they are pickled and made into preserves, and also baked in tarts, by these means they are more reconcilable to our taste. Roxb.—*Rohde M.S.S.* A fruit tree, the wood of which would appear to be of service, for making boxes, &c. Bark strongly astringent, used for tanning, and in diarrhœa. Fruits while fresh, round, the size of a gall nut, with six valves projecting externally, pulp fleshy enveloping white and angular seeds. When dry, roundish, blackish grey, very wrinkled, subhexagonal; the dried pericarp is applied to a trilocular nut, and each cell contains two red shining seeds. Odour slightly aromatic; taste acidulous, acid, astringent; in the recent state, this myrobalon is very acid and somewhat purgative; when dry chiefly astringent. It is used for tanning leather, and as a remedy in diarrhœas. An interesting account of its efficacy in the treatment of the Nusseerabad scurvy is given by Dr. McNab, in the quarterly Journal of the Medical Society of Calcutta.—*O'Shaughnessy, page* 551.

(3370) EMBLIC MYROBALON.

Amalaca, Sans.	Anola, Hind.

This is the fruit of the *Emblica officinalis,* natural order *Euphorbiaceae.*—*O'Shaughnessy, page* 341.

(3371) EMBROIDERY.—The art of embroidery was known to, and practised with great skill in ancient times in Egypt, Assyria, and Persia. The Israelites learnt the art before their exodus, the Babylonians were famed for their rich tapestries, and the Assyrian monuments display richly embroidered robes and trappings. Many parts of India are famous for this art (*Zur dozi*). "From Dacca" says the Abbe de Guyon, in 1744, as quoted by Mr. Taylor, "come the finest and best Indian embroideries in gold, silver or silk; and those embroideried neckcloths and fine muslins which are seen in France." There has always been a demand for such scarves for the markets of Bussora and Java. In the present day we have silks and woollens, muslins and nets, Cashmere shawls, European velvets embroidered with silk or *tussur,* that is, wild silk of either floss or common twisted silk thread: or with gold and silver thread and wire in great variety. Mr. Taylor describes the cloth to be embroidered as stretched out on a horizontal bamboo frame, raised about a couple of feet from the ground, and the figures intended to be worked or embroidered are drawn upon it by designers, who are generally Hindoo painters. On woollen cloths the outlines are traced with chalk and on muslin with pencil, and the body of the design copied from coloured drawings. The embroiderers, seated upon the floor around the frame, ply the needle by pushing it from, instead of towards, them. In place of scissors they commonly use a piece of glass or China ware to cut the thread.—*Royle, Arts &c. of India, page* 506. Among the embroidered articles those from Dacca and from Delhi are probably the best known. In the latter, small shawls and scarves are chiefly embroidered both with floss and twisted silk; in the former both nets and muslins, with floss silk of various colours, But Dacca is also famous

for its embroidery of muslins with cotton, which is called *chikankari* or *chikan-dozee*, and of which specimens of different articles of clothing have been sent from Calcutta; also an infant's robe of grass-cloth, worked at Serampore, and a scarf and handkerchief, pine-apple fibre from Madras. One kind is "formed by breaking down the texture of the cloth with the needle, and converting it into open meshes." Mr. Taylor states that *Kashida* is the name given to cloths embroidered with *muga* silk or coloured cotton thread; and though generally of a coarse description, gives occupation to a number of the Mahomedan females of Dacca. Though the scarves of both Delhi and of Dacca, are much admired, it has been suggested by a lady, "that muslins or nets, worked so as to be suitable for making ball-dresses, would probably be in great demand, as those which are now sold here for such purposes are very inferior in taste and elegance to the Indian embroidery. The beetle-wing embroidery from Madras was particularly elegant: and the velvet awnings, musnud covers, hookah carpets, and elephant strappings, embroidered with gold and silver, chiefly at Moorshedabad and Benares, were admired as well for richness as for the skill with which the ground-work was allowed to relieve the ornaments. The embroidered saddles and saddle-cloths, and floor-coverings from Pattiala, Mooltan, and Lahore, were of the usual style of what are called the works of that famed valley, and which was conspicuously shown in the dresses, caps, and slippers from Cashmere itself. But that the skill and taste are not confined to one part of India was also to be seen in the table-covers from Tatta in Scinde, and in the embroidered boots from Khyrpoor, which have been immortalized by Mr. Digby Wyatt.—*Royle, Arts of India, page* 507. The skill of the Chinese in embroidery is well known, and the demand for such work to adorn the dresses of officers and ladies of every rank, for embellishing purses, shoes, caps, fans, and other appendages of the dress of both sexes, and in working shawls, table covers, &c. for exportation, furnishes employment to myriads of men and women. The frame is placed on pivots, and the pattern is marked out upon the plain surface. All the work is done by the needle without any aid from machinery; there are many styles of work, with thread, braid, or floss, and in one of the most elegant, the design appears the same on both sides, the ends of the threads being neatly concealed. This mode of embroidery seems also to have been known among the Hebrews, from the expression in Deborah's song (Judges v. 30), "Of divers colors of needle work on both sides," which Sisera's mother vainly looked for him to bring home as spoil. Books are prepared for the use of embroiderers, containing patterns for them to imitate. The silk used in this art is of the finest kind and colors; gold and silver thread is occasionally added to impart a lustre to the figures on caps, purses, and ladies' shoes. A branch of the embroiderer's art consists in the formation of tassels and twisted cords for sedans, lanterns, &c.; and in the knobs or corded buttons worn on the winter caps, made of cord entertwisted into the shape of a ball. Spangles are made from brass leaves by cutting out a small ring, by means of a double edged stamp, which at one drive detaches from the sheet a wheel-shaped circle; these are flattened by a single stroke of the hammer upon an anvil, leaving a minute hole in the centre. Another way of making them is to bend a copper wire into a circle and flatten it. The needles are very slender, but of good metal; in sewing, the tailor holds it between the forefinger and thumb, pressing against the thimble on the thumb, to push it into the cloth.—*Williams' Middle Kingdom, Vol.* II. *p.* 123.

(3372) EMBRYOPTERIS GLUTINIFERA,

Coosharatha mara Toomei, TEL.

A middling sized tree, the wood is of indifferent quality. The viscid juice of the fruit is used for paying boats, and strengthening fishing nets and lines.—*Bangalore* 34.

(3373) EMERALD.

Emerande, FR.	Patchie kulloo, TAM.
Smaragd, GER.	Zamurud, ARAB.
Smeraldo, IT.	Punna, HIND.
Smaragdus, LAT.	Zimurrood, also Perma taeju, MALAY.
Esmeralda, SP.	

A precious stone, held in great estimation, and distinguished from all other gems by its peculiar *emerald green* lustre, which varies in intensity from the palest possible tinge, to a full and deep hue. The Emeralds met with in modern times do not often exceed the size of a walnut; some, however, of a larger size have been found—but such instances are rare. Localities, Egypt, New Granada, Hindustan, and Germany. The name of the *Emerald.*—(in Italian, is *Smeraldo*, from the Greek, σμαράσσειν, to shine, to be bright.) This precious stone, which ranks next to the diamond, and is equal to oriental ruby and sapphire, is of a beautiful green colour. It occurs in prisms, with a regular hexagonal base; sp. gr. 2·7; it scratches quartz with difficulty, and is scratched by topaz, and fuses before the blowpipe into a frothy bead. Its analysis has been differently stated by different chemists; but it appears to contain about 14 per cent. of glucina, (which is its characteristic constituent,) 68 of silica, 16 of alumina, and a very small portion of lime and iron: it also contains less than 1 per cent. of oxide of chromium, to which it owes its colour. The paler varieties of this stone are known under the name of BERYL: they are coloured by oxide of iron. *Aquamarine* includes clear beryls of a sea-green, or pale bluish, or bluish green tint. The

finest emeralds come from Grenada, where they occur in dolomite. A crystal from this locality, in the cabinet of the Duke of Devonshire, measures in its greatest diameter 2⅛ths inches nearly; its lesser diameter barely 2 in.; its third diameter 2⅛th in.; the extreme length of the prism is 2 inches. It contains several flaws, and is therefore only partially fit for jewellery; it has been valued at more than 500 guineas. A more splendid specimen, weighing 6 ounces, belonging to Mr. Hope, cost 500l. Both these specimens were exhibited in the Great Exhibition. Emeralds of less beauty, but of very large size, occur in Siberia. One specimen in the imperial collection of Russia measures 4½ inches in length and 12 in breadth. Another is 7 inches long and 4 broad, and weighs 6 lbs. The finest beryls (*aquamarines*) come from Siberia, Hindostan, Brazil. In the United States very large beryls have been obtained, but seldom transparent crystals: they occur in granite or gneiss. A reputed beryl of large size mentioned in most books on mineralogy has recently been discovered to be a lump of quartz.—*Tomlinson, Eng. Cyclopædia.* Prismatic corundum or chrysoberyl, is found among the Tora hills near Rajmahal on the Bunas, in irregular rolled pieces, small and generally of a light green colour: these stones are considered by the natives as emeralds, and pass under the name of "punna," but the natives are aware that they are still softer than the real emerald of India (which is generally green-coloured sapphire). See BERYL.—*Gen. Med. Top. page* 160.

(3374) EMERY.

Emeril, Emeri, FR.	Smiris, LAT.
Smirgel, GER.	Nashdak, RUS.
Smerglio, Smeregio, IT.	Esmeril, SP.

A granular variety of Corundum (*Guz. Hind.* Samada), usually mixed with iron ore. Its colour is intermediate between grayish-black, and bluish-gray. Lustre glistening and adamantine. It is used for grinding and polishing hard minerals and metals. Localities, Smyrna, Germany, Italy, Spain, &c.—*Waterston. Faulk.* This substance which, when reduced to powder, is much used for polishing hard bodies, though very different in appearance from Corundum, is on account of its hardness and analysis, regarded as Amorphous Corundum. Its colour is usually gray; its lustre is somewhat glistening. Its specific gravity is about 3·66 to 4; it occurs massive, and is granular. It is principally imported from the island of Naxos in the Grecian Archipelago, and was found by Mr. Smithson Tennant to consist of

Alumina, ...	86
Silica, ...	3
Oxide of Iron, ...	4
	93

It occurs also in Italy, Spain, and Saxony; and it is said, in small quantities, also in Wicklow, Ireland.—*Eng. Cyc. p.* 152. Corundum and its varieties, viz., Sapphire, Corundum and Emery are only surpassed in hardness by the diamond. They belong to the same class of minerals, and the emery of commerce which is so extensively used in Europe and imported into England for grinding and polishing metals, glass, &c., is supposed to be a mere variety of corundum, a mixed granular corundum; a mechanical mixture of corundum and oxide of iron, the iron in some of the varieties amounting to 33 per cent.

In the mixed corundums of Greece and Turkey the iron seems equably diffused through the mass imparting to it a bluish grey colour; but in the specimens which have reached the Madras Museum from Southern India the corundum and ore of iron, though occurring together, are not mixed, but remain apart, segregated, the corundum forming one side of a mineral and the oxide of iron, in a lump or lumps on the other side; and all such masses are magnetic and possess polarity. Of the different varieties of emery used in the arts that of Naxos is still preferred, as it is more uniform in its quality than that from Pulah and Gumuch: but it is believed that if the best qualities of Nicarian emery be found in abundance and such only sent to the market, they will prove equal, if not superior, to the emery of Naxos. That from Naxos is of a dark grey colour with a mottled surface and with small points of a micaceous mineral disseminated in the mass. It frequently contains bluish speeks or streaks which are easily recognised as being pure corundum. When reduced to powder it varies in colour from dark grey to black, but the colour of its powder affords no indication of its commercial value. The powder of emery examined under the microscope shows the distinct existence of the two minerals, corundum and oxide of iron. The specific gravity of emery is about 4, but its hardness is its most important property in its application to the arts; and those emeries which contain the least water, everything else being alike, are the hardest. The silica is

usually in combination with alumina, or the oxide of iron, or both, so that the quantity of alumina must not be regarded as an indication of the quantity of corundum in the emery. In addition to the component substances of emery, others, as titanic acid, oxide of manganese, oxide of zirconium, and sulphur, occur in some of the emeries, but in very minute quantities. These remarks have been made with the hope that the corundums of this country may be found suitable for all the purposes to which emery is now applied. The only difference in corundum seems to be the absence of oxide of iron, but there does not seem to be any quality given to the mineral by its presence in emery, essential to its value in the arts. This is a point however that I write on with diffidence. In Europe where machinery is so available, there could be no difficulty in preparing corundum powders of the requisite degrees of fineness, and its preparation in this country would perhaps be the only difficulty to be overcome. There can be no question of the great cheapness of corundum. Emery at the end of the last country was selling at from £7 to £8-10 per ton and between the year 1820 and 1835 it fell to even less than this: but a monopoly being allowed, it rose in 1846 and 1847 to £40 a ton. The discovery of other mines however at Gumuchdah near Ephesus has caused a great reduction since then, and the selling price in London has been from £10 to £25 a ton. What prices the several corundums of this country might bring in the London market it is difficult to say. There is no reason why the picked corundums should sell for less than the finest emeries, and Captain Newbold mentions that the corundums near Gram, when sorted into the three sorts known in commerce, viz., the *red*, the *whites*, and the *scraps* of these two, are sold to the Arab merchants at Mangalore and Tellicherry at prices from twelve to fifteen or thirty rupees the candy equal to £4, £6, and £12 a ton. —*Editor in Museum Report.*

(3375) ENAMEL.

Email, Fr. | Smalto, It.
Schmelz, Ger.

A kind of opaque coloured glass, formed by the combination of different metallic oxides, to which certain fusible salts are added, such as the borates, fluates, and phosphorates. There are several varieties, which are used for enamelling watch-cases, dials, jewellery, and numerous other articles. The best Enamel is that procured from Venice, which is in round cakes, about six inches in diameter, and half an inch thick.

(3376) ENAMELLING. Enamelling, or the art of fixing colours by melting in fire, is of very ancient date: it was practised by the Egyptians, and carried to a high degree of perfection in Persia. The art is known in every part of India, and some exquisite specimens were sent to the Exhibition, of 1851, both from Central and from North-western India. It is chiefly employed in ornamenting arms and jewellery, not only in gold, but also in silver.—*Royle, Arts &c. of India, page* 475. Enamels being vitrifiable substances, to which peculiar colours are given, we may compare the Indian with the European methods of making enamel. In general, ten parts of lead and three parts of tin are oxidized by continued heat and exposure to air. To the mixed oxides add ten parts of powdered quartz, and ten parts of common salt, and melt in crucibles. Thus is obtained a white enamel, and the basis of coloured enamel, metallic oxides being added. The oxide of lead or of antimony produces a yellow enamel: reds are obtained by a mixture of the oxides of gold and iron. The oxides of copper, cobalt, and iron, give greens, violets, and blues; and a variety of intermediate colours by mixtures. The workmen of Behar are stated to make two enamels, which are applied to the surface of some of the rings. One is yellow: five parts of lead are melted in a shallow crucible, and to these is added one part of tin; and the alloy is calcined for four or five hours. It is then heated to redness in the crucible of the glass-furnace. One part of white quartz is next added, and the mass stirred about for three hours. It is then taken out with a ladle, poured out on a smooth stone or iron, and cooled in water. They then take one part of their palest green glass, and add a fourth part of the other materials, to make the yellow enamel. The green enamel is made in the same manner; and to the melted glass is added, not only the prepared lead and tin, but a small portion of the black oxide of copper. In Mysore they make a bright yellow enamel, by first calcining five parts of lead and one of tin, then adding one part of zinc, calcined in a separate crucible. When these begin to adhere they are powdered in a mortar. When the maker of glass rings is at work, he melts some of this powder, and while the ring is hot, with an iron rod applies some of it (the powder) to the surface of the the glass.—*Royle, Arts of India, page* 476.

(3377) ENDIVE, Cichorium Endiva. Said to be a native of China. Used as salad, has a slight bitter taste, requires treatment similar to lettuce, should be planted on a bed elevated above the level and well manured, when properly grown they average about 15 inches in diameter. Blanched by the leaves being tied together. —*Jaffrey.* The seed of Curled and Flat-Endive may be sown in the earliest part of the rains in beds or boxes; the plants when about two inches high should be pricked out into beds, or sown in drills. They should not be nearer than one foot, and when grown to their full size, must be tied up to bleach. If in the rains, it is requisite that the plants should be every now and then opened, to let off the water that may have collected inside the plants, other-

wise they soon decay. The method adopted in England of placing a board on the plants for the purpose of bleaching, will not succeed in India, as the white ants attack them, and the board stopping the free circulation of air, prevents their growth and causes decay immediately.

(3378) ENGRAULIS ENCRASICOLUS. (Linnæus), the Anchovy (*Engraulis encrasicolus*, Fleming; *Engraulis Vulgaris*, Cuvier). This fish, which is a favourite condiment, is a native of the British seas. It has been taken in the river Dart; and Mr. Couch, in his 'Cornish fauna,' says, "This fish abounds towards the end of summer, and if attention were paid to the fishery enough might be caught to supply the consumption of the British Islands. It is abundant on the coast of Wales," and Mr. Yarrell says, "The Anchovy is reported to be at this time an inhabitant of the large piece of water below Blackwall called Dagenham breach; and in May 1838, I received one that was caught in the Thames, where however this species is so little known that the specimen referred to was sent to me with a request to know what fish it was."—*Engl. Cyc. Vol.* ii, *page* 4. See ANCHOVY.

(3379) ENKIANTHUS QUINGUE-FLORUS. On these mountains from 1,000 to 2,000 feet above the level of the sea, the Enkianthus is found growing abundantly, and in great luxuriance. It is never seen in the valleys or low lands, unless when brought down by the natives: page 128 The plant delights in fixing itself in the crevices of the rock, and is often found in such situations with very little soil about its roots. About the end of April or beginning of May, at the change of the monsoon, the wet season begins. The Enkianthus then grows most luxuriantly, and all the leaves, buds, and shoots are then fully formed: page 129. The Enkianthus is always in blossom at the time of the Chinese new year, when its flowers are in great request in the south of China for the decoration of the houses, boats, and temples, just as those of the Nandian are in the north: page 130. In going up the river towards the Fa tee Gardens I met boats in great numbers loaded with branches of peach and plum trees in bloom, Enkianthus quinqueflorus, camellias, cockscombs, magnolias, and various plants which flower at this season. The Enkianthus is brought down from the hills with the buds just expanding; and after being placed in water for a day or two, the flowers come out as healthy and fresh as if the branches had not been removed from the parent tree. This plant is a great favourite amongst the Chinese. The common jonquil too comes in for a very extensive share of patronage; and in the streets of Canton one meets with thousands of bulbs growing in small pans amongst water and a few white stones.—*Fortune's Wanderings, p.* 157.

(3380) ENKIANTHUS RETICULATUS. There are several species of Amygdalas cultivated for their flowers, and at new year's day in Canton, the budding stems of the flowering almond, narcissus, plum, peach, and the Enkianthus reticulatus, or bellflower, are forced into blossom to exhibit, as indicating good luck the coming year. —*William's Middle Kingdom, page* 283.

(3381) ENTADA PUSÆTHA. MIMOSEÆ.

Gradul. Dck.

An immense climbing shrub forming elegant festoons, legumes from one to three feet long, four or five inches broad, formed of a series of joints, each containing one seed: they are roasted and eaten.—*Riddell.* In the Tenasserim Provinces, this magnificent creeper is occasionally seen lending its light verdure to lofty forest trees, and throwing down immense pods, often more than a yard long. These pods are filled with numerous large dark brown seeds, from one to two inches in diameter. Though not in Lindley, yet the seeds of this plant enter into the native Materia Medica as an anti-febrifuge.—*Mason.*

(3382) ENTOMOLOGY, is that branch of science which treats on insects. The term Entomology literally signifies a discourse upon insects, it being derived from the two Greek words Ἔντομον, an insect, and Λόγος, a discourse. The term Entoma was first applied to these animals by Aristotle, and is synonymous with the Latin word *insecta* (whence is derived the English name 'insects'), both having reference to a striking character exhibited in the insect tribe, that of having the body insected, or, as it were, cut and divided into numerous segments. *The Entomology of the Himalayas and of India* has been noticed by the Rev. F. W. HOPE, F. R. S, F. L. S., &c, *President of the Entomological Society of London.* "It may by some be considered" he remarks, "a proof of presumption, that any individual should undertake to describe the entomo-geographical character of a country which he has never visited; and bold, he is willing to allow, is the attempt to embrace, in his views, not only the distribution of Insects in the Himalayas, but those also of the whole Continent of India and its adjacent islands. Possessing, however, one of the richest Cabinets of Oriental Entomology, to be found in England or any other country, the major part of the species collected at Calcutta, Madras, Poona, and Singapore, and in the islands of Java and Ceylon; and through the kindness of his friends, the late lamented General Hardwicke, Colonels Sykes and Whitehill, Captains Law, Smee, and Smith, having access to their rich and extensive collections from Nepal, Bombay and the Deccan; I may, he continues, be enabled, perhaps, from such a mass of materials, to offer some new facts respecting the geographical distribution of Insects, a subject apparently little studied, and certainly not sufficiently appreciated. It is, in-

deed, with diffidence that I undertake a task beset on all sides with difficulties; and before I enter on it, I claim the indulgence of my readers, and solicit them to regard the present attempt merely as an outline sketch, which can afterwards be filled up with greater accuracy, as our acquaintance with the nature of the soil, and the forms of animal and vegetable life belonging to the East, become better known. The entomological character of a country is particularly influenced by three things; first, by its temperature; secondly, by its vegetation; and, lastly, by its soil; and, perhaps, a few remarks on these subjects (relating chiefly to the Eastern world) may not here be deemed out of place, before entering more fully into the entomology of the Himalayas and of India." Dr. Royle apologized to the Rev. Mr. Hope and to his readers for the long delay which had occurred in the publishing of this valuable Paper, written for him in 1834, and which has been in type for a considerable time. The Insects of Dr Royle's collection, which Mr. Hope described, were collected in the neighbourhood of Saharunpore, in the valleys of the Himalayas, and on the mountains in the neighbourhood of Mussooree, at 6,500 feet of an elevation in 30° of N. latitude. Many of the desiderata required by Mr. H. on temperature and vegetation, are detailed throughout Dr. Royle's "Illustrations," and there is a remarkable coincidence in opinion, respecting the distribution of Insects as given by Mr. Hope, with that of Dr. Royle on the geographical distribution of the Flora of the plains and mountains of India.

Analysis of the Entomology of the Himalayas and of India.

(3383) *Cicindelidæ.*—The following genera belonging to this family are not uncommon in India, *viz.* Therates, Tricondyla, and Colliuris: the two former are characteristic of a southern range, while the latter is abundant throughout the eastern continent. Of Indian Cicindelidæ, more than sixty species have fallen under my notice: the most splendid of the race abound in Nepal. Among various species, however, peculiar to the Himalayas, only one approaches the form of European Germanica.

(3384) *Dryptidæ.*—As I am only acquainted with a single species of Indian Casnonia, I pass on to Drypta, a Nepalese individual of this family belonging to the genus Desera, Leach, which is described in General Hardwicke's collection. Five others are also recorded as inhabiting India.

(3385) *Lebiadæ*—Cymindis has not yet been discovered in India: eventually it may occur in the Himalayas: it is difficult to imagine what genus takes its place Lebia is of rare occurrence in the East: a non-descript, named unicolor, in my collection, is from the Himalayas. Aplos is found at Poona. Orthogonius is common to Africa and Asia: the gigantic species, however, predominate in the latter country.

(3386) *Brachinidæ.*—The French writers appear unacquainted with the true type of Helluo, exclusively belonging to New Holland: the genus denominated Omphra by Dr Leach, applies solely to the Indian Helluones. Ozæna and Pseudo-zæna inhabit Calcutta and Cayenne; while Trigonodactyla appears in Africa and Asia. The Graphipteræ of the sandy deserts have no representative in the East. This genus appears to unite Brachinus and Anthia: the latter is found throughout the continent of India. Some of the specimens from Nepal, however, are very diminutive. Aptinus is partly confined to Northern Europe and America; while true Brachinus enjoys the unlimited range of the world. Catascopus is found in Nepal, and resembles in its habits Elaphrus of Europe, and probably occupies its place. Dyscolus, Promecoptera, and Thyreopterus, prefer the southern tropical regions and are not found to range as far north as the Himalayas.—*Hope, M. L. J. July* 1840, *p.* 115.

(3387) *Scraitidæ.*—Siagona atrata is met with in Nepal, and various parts of India; a specimen lately received from Egypt, if not the self-same, is so exceedingly alike in size and sculpture, that it is very difficult to distinguish The Scraitidæ abound in both hemispheres. Scapterus of India is represented by Oxystomus in the Brazils, and in Africa by Acanthoscelis. Morio and Clivina will, perhaps be found in both the Old and New World; the latter, indeed, is common to all temperatures; the former may eventually occur in Europe, perhaps in Sicily.—*Hope. M. L. J. July* 1840, *page* 115.

(3388) *Harpalidæ.*—Harpali are found dispersed nearly in all the countries of the globe: they abound more in the arctic than antarctic regions. The following genera are recorded as belonging to India, *viz.* Harpalus, Platymetopus, Selenophorus, Cyclosomus, and many others. Some species of Ophonus from Bengal and Poona, closely resemble British species.—*Hope. M. J. L. J. July* 1850, *page* 118.

(3389) *Pogonidae.*—Some of the genera of this family are not confined to the temperate zones; the major part of them prefer the polar regions. Pogonus and Cardiaderus are met with in Asia and Africa; while Patrobus is apparently peculiar to Northern Europe and America. —*Hope. M. L. J. July* 1840, *page* 118.

(3390) *Calathidae.*—Dolichus has not yet been discovered in India: it is probable, however, that it will occur there. Pristonychus inhabits Nepal and Europe: while Calathus prefers a northern more than a southern climate.—*Hope. M. L. J. July* 1840, *p.* 116.

(3391) *Feroniadæ.* Instead of finding Pœcilus in India, we meet with Trigonotoma, Cata-

ENTOMOLOGY.

lromus, Lesticus, and Distrigus : most of them peculiar to that continent, Argutor antiqua occurs in the East; Omaseus and Platysma in Nepal; and Steropus in the vicinity of Poona. It is by mistake that Percus has been introduced among oriental genera. Cephalotes is found in Nepal and Australia; Stomis, Zabrus, and Pelorus prefer the temperature of Southern Europe. They may, however, be expected to appear in the Himalayas. Amara is captured in Japan; Anarctia and Masoreus are equally natives of Europe, Africa and Asia. Several nondescript species from the East, of the latter genus, are to be found in English cabinets.—*Hope. M. L. J. July* 1840, *p.* 116.

(3392) *Sphodridæ.*—The genus Sphodrus occurs in Nepal, and the anomalous form of Mormolyce in Java and Singapore; which last has been ranged with this family, but appears to be sadly out of place, as it is most likely a subcortical feeder.—*Hope. M. L. J. July* 1840, *p.* 116.

(3393) *Anchomenidæ.*—I am not aware that Platynus, Agonum, or Olistophus, have yet been discovered in India: the two former will no doubt be found in the Himalayas, when the Insects of that country are better known.—*Hope. M. L. J. July* 1840, *p.* 116.

(3394) *Callistidæ.*—Epomis and Chlænius abound in the tropics: the maculated set appear common to Asia and Africa, each country possessing species almost exact representatives of each other. Chlænius nepalensis approaches in form to Licinus; and although Oodes is widely dispersed over India, no Nepalese examples have yet come under my notice. Callistus occurs in the Mysore.—*Hope. M. L. J. July* 1840, *p.* 116

(3395) *Dicælidæ.*—Rembus is found on the Malabar and Coromandel coasts, at Calcutta, and in Nepal: its allied genus, Licinus, may be expected to occur, as some Asiatic species have already been described. Panagæus has its metropolis in India.—*Hope. M. L. J. July* 1840, *page* 116.

(3396) *Proceridæ.*—Among the Insects collected by Dr. Wallich, there were four or five species of true Carabus, only one of which I was enabled to describe. Several may occur in the colder mountain temperature, and it is probable they will resemble Siberian forms. Wherever the oak grows, there Calosoma will be found. Seven eastern species are known to me. C. indicum inhabits Nepal. If caterpillars are necessary to keep in check the luxuriance of tropical vegetation, surely the Calosomata, are equally necessary to keep within bounds these Insects, which sometimes destroy, in northern climes, nearly the foliage of the year.—*Hope. M. L. J. July* 1840, *page* 117.

(3397) *Nebriadæ.*—This family may be considered as belonging to a Northern and Alpine range. Should it occur in Nepal, it will be found at a considerable elevation, possibly amid the Himalayan snows. As to Elaphrus, I have already stated an opinion that Catascopus represents it in India—*Hope. M. L. J. July* 1840, *page* 117.

(3398) *Bembidiidæ and Trechidæ.*—Of the former family, several genera will no doubt eventually be found in Nepal: a single species of Tachys is the only example I am able to record at present. Of the latter, Stenolophus, Acupalpus and Tetragonoderus have occurred: the last of which may take the place of Bembidium.—*Hope. M. L. J. July* 1840, *page* 117.

(3399) *Dyticidæ.*—Aquatic Coleoptera are apparently not much influenced by climate: the temperature of water not varying like that of the earth or air, is the reason we meet with the self-same species in the interior of India and the south of France. Dyticus appears confined to Northern Europe or America, while Cibister is dispersed throughout the world. Eunectes and Hydaticus belong to Nepal and India, and to the latter country we may add also the following genera, *viz.* Colymbetes, Laccophilus, Noterus, Hyphydrus and Hydroporus.—*Hope. M. L. J. July* 1840, *page* 117.

(3400) *Gyrinidæ.*—Many gigantic species of Gyrinidæ abound in India. Dineutus nepalensis, politus, and spinosus, have been found within the Himalayan districts.—*Hope. M. L. J.* 1840, *page* 117.

(3401) *Hydrophilidæ.*—Several genera of this family are as widely distributed as the Ditticidæ; and most of those found in India inhabit Nepal. —*Hope. M. L. J. July* 1801, *page* 117.

(3402) *Necrophaga.*—Differing with most entomologists, I am inclined to believe that the carrion feeders abound more in warm countries than is generally believed. The religious prejudices of the Indians not allowing them to touch a dead body, may account for the few species which have hitherto reached Europe from the East. Necrophorus, Necrodes, Silpha, and Oiceoptoma, are met with in India and Nepal. It is probable that Necrophorus is more peculiarly adapted to Northern climates, while the remaining genera affect those of tropical regions.—*Hope. M. L. J. July* 1840, *p.* 118.

(3403) *Erotylidæ.*—Passing Nitidulidæ, which have been captured in India, we arrive at Engidæ and Erotylidæ. In the former family, we find Triplax, Ips, and Dacne; in the latter, Erotylus; and next to this group. Languiria and Eumorphus should be placed; genera abounding in species in Nepal and India.—*Hope. M. L. J. July* 1840, *p.* 118.

(3404) *Dermestidæ.*—In General Hardwicke's Collection, there is a Nepalese specimen of Dermestes, similar in every respect to D. lardarius

of Europe : a second species is closely allied to D. vulpinus of Africa. It is scarcely possible that either of them can have been imported into the Himalayas by commerce. This genus, and its congeners, is apparently a predominant group throughout the world.—*Hope. M. L. J. July* 1840, *p.* 118.

(3405) *Byrrhidae.*—The foreign Helocerata require attentive examination. Among the drawings of the Nepal Collection, made purposely for General Hardwicke, two species of Anthrenus are figured : they appear novel in form.—*Hope. M. L. J. July* 1840, *p.* 118.

(3406) *Histeridae.*—This family abounds in India. I am acquainted with more than fifty species from the East : some of the Nepalese specimens are in too mutilated a state to describe. —*Hope. M. L. J. July* 1840, *p.* 118.

(3407) *Lucanidae.*—I formerly described six species from Nepal : two more from the Himalayas are undescribed in Dr. Royle's Collection. In no country is there a greater admixture of temperate and tropical forms than in India ; some of the Lucanidæ resemble British species very closely, while others are the same as those in Java and Singapore. Forty species have been submitted to my inspection. Passalidæ are not equally abundant in the Old as in the New World.—*Hope. M.L.J. July* 1840, *p.* 118.

(3408) *Lamellicornes.*—The celebrated Ateuchus Ægyptiorum, or Sacred Beetle, has almost an exact representative in India. Gymnopleurus capicola, Hope, and azureus, Jab. both of them African species, are replaced in the East by G. sinuatus, Jab. and splendens, Hope. Sisyphus is met with in both hemispheres. Epirinus is an African, as well as an oriental form. Several Indian Copridæ resemble those of Egypt. Copris Midas of India and Nepal, exactly corresponds with C. Isidis of Africa. C. Sabæus and Pithecius appear common to both continents, and are equally abundant in Ceylon ; and several smaller species of Copris, from the eastern part of Africa, if not the same, approach so closely to those of Western Asia, as to induce a belief that they are the same Insects, only modified by climate. Onitis and Oniticellus have also several representatives in both regions, if not in some instances the self-same species. Onthophagus abounds more in India than any other country ; some of them unrivalled in size, splendour, and variety of form. More than 120 oriental species may be seen in European cabinets five only now are described from Nepal ; double that number, however, are in too mutilated a state to be characterized. Pactolus of Nepal and India, is represented in Senegal by Harpax, Jab. Aphodius, compared with Onthophagus, as an Indian group, is quite insignificant ; scarcely twenty species are recorded, including those of Manilla and the Eastern Isles : a nondescript from Nepal will appear in the Appendix. There was only a single specimen of Trox in General Hardwicke's collection.—*Hope. M. L. J. July* 1840, *p.* 119.

(3409) *Geotrupidæ.*—Geotrupes has been denied by Latreille to exist in India ; the Baron de Jean also makes no mention of any Eastern species from that country in his last catalogue. Two species are in my recollection ; one from Delhi, and a second from Japan ; a third also, unique, is among Dr. Royle's Insects from the Himalayas. It is probable that this genus, when found in India, appears on mountains at a considerable elevation : the species also may be the common food of the Shrikes of that country, as they are in Europe, should those birds be found there. Orphnus, Athyreus, and Hybosorus, occur in India. Bolboceas appears in some measure to supply the place of Geotrupes, which last is not so important a group in the East, as in a northern region.—*Hope. M. L. J. July* 1840, *p.* 119.

(3410) *Scarabæus.*—Under this term, the gigantic and most remarkable Insects of the Old World are ranged. Four species, allied to S. Atlas, Jab. are indigenous to Nepal, a convincing proof that equatorial forms extend beyond the tropics, and that they are found in much colder temperature than is generally believed. There are several genera of Scarabæidæ, besides Oryctes, found on the Himalayas, as yet uncharacterized ; some of them approaching African types.—*Hope. M. L. J. July* 1840, *p.* 120.

(3411) *Melolonthidæ.*—Some of the Melolonthæ of Nepal are closely allied to the British M. vulgaris ; others again, with the margins of the thorax serrated, evince their affinity to tropical species. Geniates, Apogonia, &c. are common to the Himalayas, the whole continent of India, and the Southern Isles.—*Hope. M. L. J. July* 1840, *p.* 120.

(3412) *Mimelæ and Euchlora.*—These genera appear peculiar to the East ; in a monograph, read before the Entomological Society, there are thirteen Mimelæ described ; several from Nepal. Euchlora appears wherever Mimela ranges, and is more abundant in species.—*Hope. M. L. J. July* 1840, *p.* 120.

(3413) *Popillia.*—This genus appears nearly equally abundant in Asia and Africa, and is common to the Old and New World. Fourteen species have been collected in Nepal. The following genera of Melolonthidæ, also, *viz.* Anomala, Hoplia, Apogonia, and Adoretus, occur in the same territories.—*M.L.J. July* 1840, *p.* 120.

(3414) *Trichiidae.*—Acanthurus, Trichius, and Dicronocephalus, inhabit the Himalayas. The first of these forms approaches our European type, the latter is the representative in India of what Goliathus is in Africa, and Incas in Sou-

thern America. Goliatidæ is a conspicuous family, and may justly be ranked among the most extraordinary forms of the Insect world.—*M. L. J. July* 1840, *p.* 120.

(3415) *Cetoniadae.*—Although I described seventeen species from Nepal, Dr. Royle's collection appears to contain at least six more, entirely new. Campsiura xanthorhina, Hope, is represented in Africa by Cetonia scutellata, Jab. C. cornuta, Jab. is found in Africa, as well as Asia. I am acquainted with more than 111 species from India, and from this surprising number still likely to be greatly increased, it is evident that the metropolis of Cetoniadæ is situated in the tropical regions.—*M. L. J. July* 1840, *p.* 120.

(3416) *Buprestidae.*—Of this superb and extensive family, comprising at present more than one thousand species, existing in the cabinets of Europe, the most magnificent inhabit India; the splendid Sternocera and giant Catoxantha range the Equator and the Tropics. Ninety species belong to the continent of India, many to Nepal, the isles of Java and Sumatra: among them are forms of temperate as well as of northern climes.—*Hope. M. L. J. July* 1840, *p.* 121.

(3417) *Elateridae.*—This family presents us with types of form belonging both to the tropical and temperate regions: the former, however, are few in number, when compared with the latter. Several of the Nepalese Elateridæ resemble British species, some so closely as to induce one to imagine that difference of climate is the cause of variety of the species. Elater murinus, Jab. of England, is well represented in Nepal by Elater cœnosus, Hope; and various species, which in Europe frequent the oak, alder, and willow, have Nepalese species nearly resembling them, and we have stated that there is a correspondence of vegetation between Europe and the Himalayas. —*Hope. M. L. J. July* 1840, *p.* 121.

(3418) *Lampyridae.*—Passing the Cebrionidæ, few examples of which occur in India, we arrive at the Lampyridæ; and justly may the East boast of its numerous and fine species, unsurpassed probably by those of South America. The warm damp of the jungle is peculiarly adapted to the habits of this family. Lycus and Omalysus, as well as Lampyris, abound in the Himalayan range.—*Hope. M. L. J. July* 1840, *p.* 121.

(3419) *Malacodermata.*—By some writers, the families composing this group are considered rare within the Tropics, and they certainly are more abundant in Nepal than Central India; and yet they are not of rare occurrence. Anisotelus, Hope, appears to be peculiar to the East. Several species of Malachius and Melyris enjoy an Asiatic and African clime.—*Hope. M. L. J. July* 1840, *p.*121.

(3420) *Cleridae.*—By the family Cleridæ, abounding in the East, we arrive at the Ptinidæ; they, the latter probably, exist in Nepal; none, however, I believe, have yet been discovered in India, the nearest locality where they are found being the Mauritius. The Bostrichidæ are, however, abundant, and it is not unlikely that the Paussidæ commence where the Ptinidæ terminate.—*Hope. M. L. J. July* 1840, *p.* 121.

(3421) *Curculionidae.*—Without entering at large into the geographical range of the numerous genera of this family, I briefly state, that Nepal contains many tropical forms, as well as others, which are peculiar to temperate climes, some of them extending from the Himalayas, even to New Holland, particularly Sipalus.—*Hope. M. L. J. July* 1840, *p.* 122.

(3422) *Prioridae.*—By the Cucujidæ (common to India and Nepal) we arrive at the Longicornes. Prionus loves the torrid and tropical zones: some of the Himalayan species indicate an alliance to European types.—*Hope. M. L. J. July* 1840, *page* 122.

(3423) *Lamiadae.*—The largest, as well as the most beautiful species of this family, are found in Nepal. Lamia Roylii, Hope, is unrivalled in size; and L. Wallichii surpasses all others in beauty and colouring; it is found in Nepal, Japan, at Singapore, and the Isle of Java. Cerambyx, Callidium, Clytus, and Saperda, are predominant groups, and are found in all countries and climates. Many Nepalese species exactly represent our European types.—*Hope. M. L. J. July* 1840, *page* 122.

(3424) *Sagridae.*—Omitting Lepturidæ, confined almost entirely to Northern Europe and America, we arrive at Sagridæ. Donacia occurs in Java, and we may expect to meet with it in Nepal, and other parts of India; if not, it is probable that Sagra takes the place which Donacia does in northern regions. Several species of this genus are found on the Nympheacæ. I am doubtful if Sagra attaches itself to peculiar water-plants, or frequents the same as the former genus. Megalopus is found in Nepal, in Africa, as well as South America. Crioceris also appears to be a predominant group, while Adorium is confined more to Asia than Africa.—*Hope. M. L. J. July* 1840, *page* 122.

(3425) *Galleruoidae.*—Galleruca and Auchenia abound in Nepal. Halticæ are found throughout the world, and are intended probably to keep in check particular vegetation. In Europe, the genera Brassica and Sinapis almost annually suffer from their depredations; they appear to abound more in light and sandy soils; and where lime is used instead of animal manure, the crops are less attacked.—*Hope. M.L.J. July* 1840, *page* 122.

(3426) *Chrysomelidae.*—Many of the Nepa-

lese species resemble those of Siberia; others approximate closely to our European forms, so much so, that in many instances they appear like one and the self-same Insect; and if not the same, they are certainly similar representatives of their respective countries, and probably fulfil the same offices and functions. Podontia and Phyllocharis seem peculiar to Asia and New Holland.—*Hope. M. L. J. July* 1840, *p.* 123.

(3027) *Eumolpidae.*—The Eumolpidæ of India are not surpassed in beauty or splendour by those of South America; they seldom, however, equal the latter in size. Clythra and Cryptocephalus occur in the East, both of them abounding more in temperate than tropical countries; in Dr. Royle's collection there are found several undescribed species from the Himalayas.—*Hope. M. L. J. July* 1840, *p.* 123.

(3428) *Cassididae.*—About fifty species of Indian Cassida have come under my notice; some of the Napalese species resemble English specimens, and may be parasitic on the thistles, as they are there.—*Hope. M. L. J. July* 1840, *page* 123.

(3429) *Coccinellidae.*—Although I described twenty new species from General Hardwicke's collection of Nepal Insects, I find five others undescribed in Dr. Royle's collection from the Himalayas. Coccinella 7-puncata, Fab., appears common to Europe and Asia; at least the specimens agree so exactly in every respect, that after a very accurate examination, no important difference can be found; and believing them to be the same, I still cannot imagine that they have been imported into India by commerce. Endomychus may eventually be expected to occur in Nepal.—*Hope. M. L. J. July* 1840, *p.* 123.

(3430) *Hispidae.*—Hispa crinacea is abundant in Nepal; and two undescribed species are in Dr. Royle's collection from the same country.—*Hope. M. L. J. July* 1840, *p.* 123.

(3431) *Tenebrionidae.*—The transition from Hispidæ to the present family by means of Sarrotrium is rendered easy. Hegeter and Tagenia, common to India, appear to follow in successive order. Both Upis and Tenebris are found in the Himalayas, and are abundant in the Tropics.—*Hope. M. L. J. July* 1840, *p.* 123.

(3432) *Pimeliariae.*—Pimelia has not yet been described as existing in India; last year I received two species from the vicinity of Poona. Sepidium, Blaps, Eurynotus, and Opatrum, occur in the East; the first prefers the Southern Tropic; the two next appear at Bombay, Calcutta, and Nepal; and the last is widely dispersed throughout the East. Passing Diaperidæ and Cossyphus, both of them common to Asia and Africa, we next meet with Cistela and Lagria: the latter apparently a predominant group. Pyrochroa, also, has been discovered in Java.—*Hope. M. L. J. July* 1840, *p.* 124.

(3433) *Helopidae.*—This family is the grand receptacle for the various forms of Heteromera. Among the Indian genera we find Amarygmus, Cnodulon, and Platycrepis, with several true Helopidæ, rivalling in splendour and magnitude those of the South American Continent.—*Hope. M. L. J. July* 1840, *p.* 124.

(3434) *Mordellidae.*—Most of these Insects are parasitics of the Hymenoptera, and abound in tropical climates. Their office is probably to keep in check, and prevent the too rapid increase of Vespidæ and Bombidæ: they are common to the Old and New World.—*Hope. M. L. J. July* 1840, *p.* 124.

(3435) *Cantharidae.*—The geographical distribution of this family is particularly interesting as it contains those Insects which are used in Medicine, and denominated Blister Flies. Lytta gigas, Fab., is found abundantly in India, and also in Senegal; and there is little doubt that several species of Mylabris will be found common to both continents. These vesicatory Insects of the Old World are replaced in the New by the genus Tetranyx.—*Hope. M. L. J. July* 1840, *p.* 124.

(3436) *Staphilinidae.*—By the families Notoxidæ and Scydmænidæ, we arrive at the Pselaphidæ, and afterwards at the Brachelytra, which terminate the Coleoptera. Anthilephila and Notoxus occur in Nepal, and Scydmænus in Java; while various other genera of Staphilinidæ are widely dispersed throughout the East.—*Hope. M. L. J. July* 1840, *p* 124.

(3437) *On the Remaining Orders.*—Having entered fully into the consideration of Eastern Coleoptera, it is not my intention at present to go into lengthened details of the remaining Orders. It is sufficient to state, that in all of them there will be found similar and corresponding characters as in the Coleoptera. With regard to identity of species, I cannot help remarking, that of Lepidoptera, there appear to be a much greater number of species, widely disseminated throughout the world, than of any other order. In Asia and Europe we meet with Papilio Machaon, Gonepteryx Rhamni; with some species of Colias and Pontia, with Vanessa Atlanta, and Cynthia Cardui; and to these might be added, several identical Sphingidæ, particularly Acherontia, Atropos, Deilephila, Celerio, and Spynx. Among the Noctuidæ, Geometridæ, Tortricidæ, and Tineidæ, many species will also be found inhabitants of both continents. In the Orthoptera, some Gryllidæ are common to countries remotely situated, which may partly be accounted for by the migratory habits of these Insects; and the same remarks may be applied to the Sphingidæ. Among the Blattidæ, several tropical species range widely;

some of them have become naturalized even in a northern climate; and it is no uncommon occurrence to find Indian, Brazilian, and New Holland, species in a high state of perfection alive in the houses of London; and among the Eastern Neuroptera, there occur various Libellulinæ and Hemerobeidæ, closely resembling English species. Among the Hymenoptera, may be noticed the universal ranger, Evania appendigaster, ever attendant on Blatta; some Icheumonidæ, Crabronidæ, Apidæ, and Vespidæ, all of them presenting identical species with those of Great Britain. In referring to the Diptera, I need only mention the wide range of the Orange Fly, the same in England, India, and America; the Gnats and Mosquitoes, common to the four quarters of the globe, alike the pest of the Indian and Laplander; and, lastly, various species of Musca, as widely dispersed as the half-domesticated sparrow of Great Britain. Passing by the Aptera, and the various parasites of birds, quadrupeds, and of man himself, we shall find also among the Hemiptera, several identical species of Pentatoma, Reduvius, Tetyra, besides Cimex lectularius the scourge of all countries and climates. It does appear, then, from the above analysis, that Asia and Europe have many Insects in common, and probably other parts of the world will eventually be found to present not only similar genera and representatives, but also the same identical species, subject to the modifications of climate, and other external circumstances —*Hope. M. L. J. July* 1840, *p.* 125.

(3438) *Character of Himalayan Entomology* —The character of Himalayan Entomology is twofold, Asiatic and European; and the intermingling of forms of temperate and tropical climes is one of its most distinguishing peculiarities. In its valleys (probably influenced by the heat and moisture of the jungle) southern forms predominate over northern; and it is not unlikely, that to the uninterrupted belts of jungle stretching along the mountain ranges, we may partly trace several tropical phytyvorous genera far beyond their apparent natural limits. Some carnivorous Insects are also found ranging far to the north in the Himalayas; an example of which is Anthia 6-guttata, a well-known native of the Tropics: the specimens, however, are mere dwarfs, compared with those of Peninsular India, a fact which may be regarded as a proof, that Anthia has here reached its extreme limits, and consequently will soon disappear (as is the case) and be represented by another type, fulfilling the same functions, only under a difference of form. The following genera of Himalayan Insects, selected from many others, will evince their tropical relationship. Among the Cicindelidæ, Colliuris appears; among the Carabidæ, we find Desera, Omphra, and Cyclosomus; among the Lamellicornes, Euchlora, Mimela, and Dicronocephalus; and to these may be added, Anisotelus belonging to Telephoridæ, and Podontia and Phyllocharis to the Chrysomelidæ: all of them attached to warm countries, and some, indeed, are seldom found but within the Torrid Zone. It is needless to state many genera from the Himalayas evincing an affinity to European types; I may here add, that various Himalayan genera closely approximate Siberian forms, and that some of the species described by Dr. Gibler from the Altaic chain of mountains, particularly some Chrysomelidæ, I believe to be indigenous in both regions. Some few, however, are worth noticing, such as Broschus and true Carabus, Geotrupes and Pimelia; the two last have been declared by high authority never to be found in India. Regarding identity of Insects occurring in the Himalayas, as well as in Europe, there are several species of the following genera of Celeoptera, namely, Elater, Melontha, Chrysomela, Cassida, and Coccinella, which I cannot help thinking are the same as those of England; particularly as the vegetation of the two countries greatly coincide, for in very many cases, genera, and in some instances the self-same species of plants have been recognized. Among the carnivorous Insects, I believe that Dermestes lardarius, and vulpinus, Corynetes violaceus, and rufipes, and some of the Staphilinidæ, are essentially the same in Europe and the Himalayas. Of Lepidoptera, I figure Papilio Machaon, because it is evidently the same as what we meet with in England; the same remark will apply to Vanessa Atalanta, and Cynthia Cardui. The French entomologists are inclined to regard the Insects of widely separated countries as distinct species; I wish to esteem them as varieties, and I cannot help thinking, that as identity of Plants has been satisfactorily proved by Dr. Royle, so also we may believe in the identity of Insects in regions widely removed from each other. At any rate, should these varieties eventually prove distinct (which may be ascertained, I think, in the Lepidoptera order, when we become better acquainted with the oval, larval, and chrysalidous stages), yet the difference will ever be so slight, that we cannot separate or distinguish them in the image state with any degree of certainty. But whether they be accounted species, or only varieties, we see the grand object of their creation, in their fitness for performing certain functions which are assigned them; one of these is, to keep in check the luxuriance of vegetation and to restrain it within due limits; another may be, that these puny agents may fecundate the flowers, by carrying the fertilizing pollen from tree to tree, and thus be the means, in one case, of promoting vegetation, as in another they are the agents of its destruction.—*Hope. M. L. J. July* 1840, *page* 127.

(3439) *Entomological character of India.*— From the foregoing Analysis, I have no hesitation in asserting that the pervading character of

Indian Entomology is uniformity. It is true that we meet with numerous genera, both of tropical and temperate climes, associated together; the former more abundant, the latter less frequent (as we might naturally expect) than in the Himalayas. There is, however, a greater intermingling of forms than at first sight would be readily imagined; but when we take into our consideration, that many of the species resembling those of Europe may have been captured on the mountain ranges, at a considerable elevation we may partly account for it. This attempted explanation, however, is not always available or satisfactory; for in the heated valleys of the East, we find many European types and species, in numbers sufficient to excite our astonishment. It will appear, then, that many species taken in temperate and northern climes, are not confined to them, and that the range they enjoy is very considerable, extending not only over the Old World, but also to the New. As we advance from the Poles to the Equator, vegetation is more luxuriant, in proportion as heat increases, and the quantity of work assigned to Insect races is proportionately increased. Is it not natural to imagine that the functions performed by them in a colder climate, would in a warmer one require increased exertion and capabilities? It does not follow, because we find new types of form in tropical countries, and new genera of superior bulk and power, and more abundant in individuals, that therefore they necessarily replace the old ones, and are to perform the duties peculiar to both regions; both may live and thrive together, and abound in the same countries, and will eventually be found to do so. When the genera of temperate climes appear within the Tropics, I see no reason why they may not have the same functions assigned them there, as in colder latitudes; but when we find new types of form, and a more powerful organization, with the size of the Insects greatly increased (as is the case in tropical regions), does it not almost naturally follow that they are intended solely for those regions, and for the increase of work they are there destined to perform? To return, however, to the subject of uniformity of entomological character throughout the Peninsula and the East, I think it probable that it is in a great measure to be accounted for by the general uniformity of its temperature, vegetation, and soil. There may, indeed, be other causes, which particularly influence it, but these may be esteemed the most essential. When we look to the range which genera here enjoy, it is very considerable: in part of the Himalayas, at the extreme southern points of India, in the West, and even in its Eastern Isles, there is one pervading character, evincing every where the prevalence of tropical genera. To speak more specifically, in Nepal and the southernmost extremity of the Mysore, and in Ceylon, at Bombay, and at Madras, at

Calcutta and Singapore, in Japan and Java, with the rest of the Polynesian Isles, the majority of the same types abound; and what is of more consequence, a great majority of the same species also occur in most of the above-mentioned regions. Having noticed the intermingling of genera belonging to Europe and Asia, we may probably find a slight accordance elsewhere. Now, if we turn our eyes to Africa, we shall there find a considerable similarity in the entomology of this quarter of the globe with that of Asia; and this resemblance between the two countries will be readily seen by the short annexed list of some of the more particular genera, which are common to both of them. Among the Carabidæ occur Anthia, Orthogonius, Trigonodactyla, and Siagona. Among the Lamellicornes, Epirinus and Popillia, the conical Buprestidæ and the extraordinary Paussidæ, which last are chiefly found only in these regions; and to these may be added, as well as many more, the genera Melyris, Megalopus, Sagra, and Adorium; Dorylus, among the Hymenoptera, and Diopsis among the Diptera. Passing from genera to species, we shall find that precisely the same occur in both continents; among the most conspicuous, I shall mention but a few, namely, Copris Midas, Sabæus, and Pithecius, Cetonia cornuta, and Lytta gigas. Even supposing that no identical species occurred, which were common to Asia, and Africa, yet we could not help observing the very remarkable similarity in the representatives of each; one example of which is, Ateuchus sanctus, which very closely resembles the celebrated Sacred Beetle of the Egyptians, the object of their worship, by some regarded as an emblem of fertility, but I think more probably that of eternity. Before concluding my remarks on the similarity of Insects found in Asia and Africa, I cannot help expressing a wish that some individual may be induced to develope the character of the entomology of these gigantic regions more thoroughly than has yet been attempted; as there is an ample field for research and speculation. We shall feel much indebted to him, if he will explain how the Copridæ were transported from one country to another, and how they reached the island of Ceylon; how also Cetonia cornuta, which is taken on the banks of the Gambia, became an inhabitant of India. Lytta gigas may have travelled by land, and perhaps the Copridæ following the track and droppings of the camel, may have pursued the same route. Let him describe the sands of the desert and those in the vicinity of the Indus, give us a comparative Fauna of the Ganges and the Nile, record the varieties of temperature, the character of vegetation, and the genera peculiar to the different soils. Let him do this, following the steps of the celebrated Forskahl, and he indeed will advance the objects of science, deserve the thanks of the present generation, and command

the respect of posterity. By pursuing the course recommended by Mr. Hope, a naturalist would be enabled, not only to display the connection between soil, temperature, and vegetation, as well as the animal forms which the latter supports, but also prove the advantages of studying the natural sciences in connection with each other, and be enabled to explain something of the laws which influence the geographical distribution of plants and animals.—*J. F. R.—Hope. M. L. J. July* 1840, *p.* 129.

(3440) ORDER DERMAPTERA, Leach.

Family Forficulidæ.

Forficula Macropyga, Westw.

Piceo-nigra, punctata, abdomine æneo submicante, marginibus thoracis, tegminibusque rufescentibus, forcipe (♂) longissimo valde curvato, et gracili; (♀) fere recto tenuissimo.

Long. Corp. (forcipe excluso) ♂ lin. 6 ♀ lin. 5.

Ad genus Forficulam (stricte sic dictum Servilleo) appertinet, statura fere Forficulæ auricularіæ et paullo robustior, caput nigrum punctatum, impressionibus duabus anticis inter oculos. Antennæ ♀ (♂ mutilatæ) 13-articulatæ graciles rufescentes, articulis bassalibus obscurioribus.—*Prothorax* planus antice vix emarginatus, lateribus antice rectis, postice rotundatis, niger punctatus, margine tenui rufescenti; foveolis duabus rotundatis, antice impressus.—*Tegmina* piceo-rufescentia, punctata, portio alarum detecta concolor. *Abdomen* nigro-picum punctatum æneo submicans; segmento penultimo lateraliter et angulariter producto (♂) aut simplici (♀). Forceps (♂) niger valde elongatus, gracilis ad basin, valde externè curvatus, in medio, dentibus duobus parvis internis instructus, apice sursum et exterius producto, acuto (♀) elongatus multo gracilior, rufescens fere rectus et inermis.—*Westwood. M. L. J. July* 1840, *p.* 130.

(3441) ORDER LEPIDOPTERA, Linn.

DIURNA. Family Papilionidæ.

Papilio Machaon, Linn.

This handsome butterfly, like Vanessæ Antiopa, and Atalanta, Cynthia Cardui, and some others, affords an instance of wide geographical range, [Messrs. Godart and Latreille, in the Encyclopédie Méthodique (Vol. IX., Art. Papillon) state, that Pap. Machaon is found in Syria and Egypt] rather than of representative structure, since the individual figured cannot be regarded as specifically distinct from the European specimens, which differ amongst themselves in various slight particulars, as the size of the dark bars, and spots, &c. It may, however, be noticed, that the specimen figured has the small oval black spot near the extremity of the anterior wings almost entirely isolated, the large basal black portion of the same wings is very strongly covered with yellow powder, whilst the black lunules of the posterior wings are not nearly so much powdered with blue bloom, as in the ordinary English specimens.—*Westwood. Hope. M. L. J. July* 1840, *p.* 130.

Fam. Nymphalidæ.

Paphia Parakekta, Horsfield. Lepidopt. Javanica.

Paph. alis anticis ad apicem acutis, posticis subcaudatis; anticis supra ad basin cæruleis, fascia obliqua lata fulva in medio, apiceque nigro; maculisque duabus parvis albis (una discoidali, altera apicali) ornatis; posticis cæruleis.

The preceding characters, drawn from the upper surface of the wings of this remarkable butterfly, suffice for its determination until the publication of Dr. Horsfield's description. The under surface of the wings are, however, much more remarkable, bearing a most striking resemblance to a pale dried leaf; the deception being much increased by the form of the wings, when brought in contact by the Insect, whilst sitting upon a flower in the sun-shine, the short caudal appendages giving rise to the idea of the stalk of the leaf, thus completing the delusion.—*Westwood. Hope. M. L. J. July* 1840, *page* 131.

DIVISION ?——— ? Fam Zygænidæ ?

Genus Campylotes, Westw.

Genus anomalum Heleonæ et Anthonoyzæ &c. Gymnanto cenæque *Guér*, affine, alæ oblongæ, subovales, integræ, nervis apicalibus valde curvatis, anticæ cellula discoidali clausa nervos duos postice emittens, quorum exterior trifurcatis, posticæ etiam cellula discoidali clausá, nervo recurrente intermedio bifurcato. Corpus parvum abdomine gracili, pone alas haud protenso. Caput parvum. Ocelli 2. Antennæ graciles biramosæt Palpi brevissimi supra haud discernendi, maxillæ elongatæ spirales.

Campylotes histrionicus, Westw. Æneus, alis ad costam ruso—, interne flavo-lineatis, maculisque apicalibus albis. Long Corp. lin. 11. Expans. alar. unc. 3. Habitat in Nepalia. Hardwicke; in Montibus Himalayanis. Royle. Corpus nigro-æneum, palagris maculisque abdominalibus lateralibus flavis. Alæ anticæ aneæ costa, fasciisque duabus discoidalibus rufis, fasciisque tribus internis per totam longitudinem alarum currentibus flavis; maculis 8 vel 9 (spatium inter nervos apicales occupantibus) albis Alæ posticæ, similiter coloratæ, at maculæ terminales flavo ornantur. This remarkable Insect appears to be the extreme type of a very numerous Indian group of Lepidoptera, to which belong the species named Capys pectinicornis, Thallo, and Rhodope. It is impossible to decide upon their real affinities, until we obtain a knowledge of the metamorphoses of some of the species.—*Westwood. M. L. J. July* 1840, *page* 131.

(3442) ORDER ORTHOPTERA. Fam. Mantidæ.

Mantis Roylii, Hope, MSS.

(3443) ORDER HYMENOPTERA. Section Pupivora.

Fam. Chalcididæ.

Dirhinus Himalayanus, Westw.

Niger, pedibus 4 anterioribus, tarsisque posticis rufescentibus. Capite obtuse bicornuto. Habitat in Himalaya. Long.corp. lin. 2. Exp. alar. lin. 3.

Caput nigrum punctatum, antice obtuse bicornutum antennarum articulo primo nigro (articulis reliquis deteritis).Thorax fortiter punctatus; metathorace 4 lineato et ad latera,angulariter producto. Abdomen breve depressum thoracis latitudine. Pedes 4 anteriores rufuscentes, 2 postici, nigri, tarsis solummodo rufescentibus.

Obs. In hac specie partes oris valde elongatæ, labro oblongo-ovali ciliato, mandibulis inter se similibus, gracilibus, sub apice dente interno unico armatis.—*Westwood. M. L. J. July* 1840, *page* 132.

(3444) ORDER HETEROPTERA. Section Longilabres.

Fam. Scutelleridæ.

Scutellera Pulchella, Hope, MSS.

Cæruleo-nigra vel-æneo, nitida prothoracis disco antice, et margine postico æneo vel cupreo cincto, scutello aureo viridique intenti, fascia transversa basali, alteraque centrali obliqua, (in medio interrupta) et maculis tribus rotundatis (postice et in triangulum positis) cæruleo-nigris.

Statura fere Scutelleræ mauræ at paullo minor, scutelloque abdomen omnino obtegenti. Scutelleræ Stockeri affinis at robustior. Antennæ articulis duobus basalibus brevibus equalibus. 3tio. 2do. fere duplo longiori, ultimo omnium longissimo. Long. corp. lin. 5. lat. lin. 3.—*Westwood. M. L. J. July* 1840, *page* 132.

Fam. Pentatomidæ.

Megarhynchus Transversalis, Westw.

Fusco-niger, capite acuté bicornuto, angulisque anticis thoracis acuté antice productis, prothorace et scutello transverse striatis, parte coriacea hemelytrorum nigra, tenuissime punctata, membrana apicali albida. Antennæ et pedes nigri. Long. corp. lin. 7½. lat. lin. 3½.—*Westwood, M. L. J. July* 1840, *page* 132.

(3445) ORDER HOMOPTERA. Section Saltatoria.

Fam. Acadidæ.

Cicada Sulphurea, Hope, MSS.

Nigra, capite thoraceque sulphureo maculatis, alarum dimidio basali sulphureo, parte anticarum sulphurea, fascia obliqua nigricanti divisa, apicibusque fuscescentibus. Long corp. unc. 1½. Expans. alar, unc. 3¾.—*Westwood. M. L. J. July* 1840, *page* 132.

Affinis Cicadæ maculatæ. Caput nigrum orbitu interno oculorum sulphureo; thorax niger maculis 8 sulphureis abdomen nigrum segmentorum marginibus pallidis. Alæ anticæ costa sulphurea, maculáque ovali maxima (plus quam dimidium basale alarum occupante) sulphurea fascia obliqua tenui nigra interne dentata divisa; apice fusco nervis nigris Alæ posticæ ad basin sulphureæ, ad apicem fuscæ nervis nigris; pedes nigri. —*Westwood. M. L. J. July* 1840, *p.* 133.

(3446) ORDER DIPTERA. Section Pupipara.

Fam. Hippoboscidæ.

Hippobosca Maculata.

Thorace fusco, flavo variegato, scutello nigricanti, maculis tribus flavis, media majori, femoribus tibiisque posticis ad apicem fuscis.

Hippobosca equina; " ex India orientali paullo major, thoraceque magis albo variegato, at vix distincta." Fab. Syst. Antl. p. 338.

Hippobosca maculata, Leach, " on the genera and species of Eproboscideous Insects." Wernerian Trans. vol. ii. p. 549. Long. corp. lin. 4 Expans. alar. lin. 8¾. Caput flavum, oculis fulvis, linea longitudinali inter oculos fusca. Proboscis nigra. Thorax fuscus, macula magna ad angulos anticos flavescenti in medio fusca; fascia parva centrali lunulisque duabus in medio conjunctis posticis flavescentibus, scutello nigricante maculis tribus flavis media majori. Abdomen fuscum, punctatum, marginibus rufescentibus. Pedes fulvescentes tarsis omnibus femoribus tibiisque posticis ad apicem fuscis.—*Westwood. M. L. J. July* 1840, *p.* 133.

Fam. Nycteribidæ.

Nycteribia Roylii.

Obscure nigra pedibus fuscescentibus elongatis, vix compressis, coxis anticis brevibus, abdomine ovalo, conico, depresso, 5-articulato, apice subtruncato, stylis duobus incurvis subtus armato, capite compresso. Long. corp. lin. 1⅓. Habitat in India Orentali. Nyct. Roylii. Westw. in Trans. Zool. Soc. 1. p. 290-5.—*Westwood. M. L. J. July* 1840, *p.* 133.

(3447) ORDER COLEOPTERA.

Cetonia Roylii, Hope.

Long. lin. 12. lat. lin. 6. Nigro-viridis thorace flavo marginato elytrisque quatuor maculis flavis notatis. Clypeus quadratus. Antennæ nigræ. Caput quadratum punctatum, Thorax cupreis marginibus externis elevatis, lineaque flava utrinque externa, disco fortissime punctato. Scutellum magnum postice decitum. Elytra nigro-virescentia maculis quatuor flavis

notata, binæ fere rotundatæ ad basin posi-æ, binæ aliæ reniformes ante apicem locatæ. Corpus infra nigro-æneum segmentis abdominis utrinque aurantiis capillis obsitis pedibusque con-oloribus. In Mus. Dom. Royle; in montibus Himalayæ captus ceria.—*Westwood. M. L. J. July* 1840, *page* 134.

(3448) GEOTRUPES ORIENTALIS.

Long. lin. 10. lat. lin. 6½. Violaceus thorace parsim punctulato, elytris striatopunctatis, pedi-ous supra nigris, infra violaceis nitidis. Anten-næ piceæ capitulo fuscanti, thorax violaceus ongitudinali serie punctorum in medio posita, variis aliis sparsim dispositis. Elytra striato punctata striis quasi vermibus erosis. Corpus nfra violaceum nitidum, femoribus posticis uni-pinosis, tibiis pilosis, tarsis chelisque piceis. This singular species approaches very closely to ome of the British species, and is probably from high elevation of the Himalayan mountains. n Mus. Dom. Royle.—*Westwood. M. L. J. July* 1840, *page* 134.

(3449) ONTHOPHAGUS PHANÆOIDES.

Long, lin. 4½. lat. lin. 4¼. Niger obscurus, clypeo cornu reflexo abrupte truncato, thorace phanæoformi, postice lateribus in spinam obtusam productis, femoribus luteis. Antennæ piceæ capitulo fuscanti: clypeus hexagonus cornu re-verso abrupte truncato, thorax fere quadratus: punctatissimus, punctulis erosis tuberculo antice, fossulaque postice in medio marginis impressa, angulis posticis in spinas productis. Scutellum parvum nitidum. Elytra striata. Corpus sup-us atrum nitidum punctatum. Pedes femori-bus luteis, tibiis tarsisque nigropiceis. This singular insect will, at some future period, form the type of a new genus: in form it unites the South American Phanæus, and the widely-dis-seminated genus Onthophagus,—*Westwood. M. L. J. July* 1840, *page* 134.

(3450) LUCANUS LUNIFER.

Long. lin. 37. lat. lin. 10. Æneo-piceus, cereolo tomento aspersus, mandibulis exertis uni-dentatis, denticulisque minoribus instructis, apice bifurcatis. Clypeo deflexo lunifero, femoribus castaneis. Hab. in Montibus Himalayæ; in Mus. Dom. Royle. This Insect appears to unite in itself the characters of the Asiatic and Europe species, the latter rather predominating over the former: it is one of the finest forms of the Himalayan Fauna.—*Westwood. M. L. J. July* 1040, *p.* 135.

(3451) LAMIA WALLICHII.

Long. lin. 16. last. lin. 5. Viridisericeus, an-tennis penicillatis, elytris tribus fasciis nigris, binisque penicillis ornatis. Antennæ corpore lon-giores et nigrovirides, primo articulo subpenicil-lato, tribus sequentibus atris, penicillis magnis bilobum barbatis, et reliquis pubescentibus, ultimo annen pubescentia densiori tecto. Thorax viri-

dis, spinosus. Elytra ornata tribus fasciis vix suturam attingentibus, una in medio elytrorum, secunda inter mediam et apicem, tertiaque binis penicillis dorsalibus interrupta. Corpus subtus nigro-virens, sanguinea pubescentia aspersum. Segmenta quatuor abdominis sanguineo colore fucata, ultimum omne autem viride et nitidum. Pedes viridi-pubescentes, femoribus macula rufa notatis tarsisque infra flavis. It is impossible to describe accurately the beauty of this Insect; the sericeous covering, in different lights, imitating the various tints of opal, while the dark fasciæ flash with the iridescence of Labrador felspar.—*Westwood, M. L. J. July* 1840, *p.* 135.

(3452) PORUS, Hope.

{STENIDÆ, ML.
{LONGIPALPI, Lat.

Corpus oblongum fere parallelum subdepres-sum. Caput mediocre oculis magnis lateralibus. Antennæ crassæ articulis transversis. Mandibulæ acutæ dente interiori armatæ. Labrum transver-sum integrum ciliatum. Maxillæ elongatæ bilo-batæ. Palpi maxillares longitudine mediocres arti-culo 3tio. longo clavato, ultimo minimo. Labium elongatum apice lanceolato, paraglossis lateralib-us. Palpi labiales breves, articulo ultimo parvo conico. Thorax fere circularis. Abdomen elong-atum marginatum. Pedes simplices. Tibiæ cal-caribus binis armatæ. Tarsis articulis simplicibus. PORUS OCHRACEUS. Long. lin. 4. lat. lin. ¾. Ely-tris punctatis antennis fuscis, mandibulisque ad apicem nigris. Hab. in Montibus Himalayæ; in Mus. Dom. Royle. This genus somewhat ap-proaches the European Evæsthetus.—*Westwood. M. L. J. July* 1840, *p.* 135.

(3453) APHODIUS.

APHODIUS IRREGULARIS, Hope.

Long. lin. 4. lat. lin. 2. Flavus thorace nigro, elytris subaurantiis, fascia media maculis quatu-or nigris, pedibusque piceis. Antennæ piceo capi-tulo fusco. Caput angulis anticis oblique trun-catis. Thorax niger nitidus punctatus, angulis anterioribus flavis. Elytra flava, seu subauran-tia, fascia media irregulari nigra, binis maculis humeralibus, binisque aliis fere ad spicem locatis concoloribus. Hab. in Montibus Himalayæ; in Mus. Dom. Royle.—*Westwood, M. L. J. July* 1840, *p.* 136.

ANISOTELUS, Hope.

(3454) TELEPHORIDÆ.

Antennæ articulo Imo. crasso, reliquis multo crassiori, 9-10 obconices magnitudine paululum crescentibus ultimo majori ovato apice acuto. Mandibulæ valde acutæ. Maxillæ membranaceæ lobo unico intus tomentoso. Palpi articulo 1 mo. minimo. 2do. et quarto æqualibus, ultimo sub-securiforme. Mentum transversum. Labrum mem-branaceum fere rotundatum. Palpi labiales brev-es, articulo ultimo majori securiformi. Caput

transversum oculis prominulis. Thorax transversus lateribus rotundatis, angulis posticis acutis elevatis. Elytra sicut in Telephoris, in medio nonnihil dilatata. Tarsi 5-articulati, articulo penultimo bilobato.—*Westwood. M. L. J. July* 1840, *p.* 136.

(3455) ANISOTELUS BIMACULATUS, Hope.

Long. lin. 4½., lat. lin. 2. Lividus, elytris 2-maculatis. Antennæ articulo primo testaceo, reliquis fuscis. Thorax rufo-testaceus nitidus, elytris pallidioribus macula ovali nigra in singulo fere ad apicem posita. Corpus infra testaceum. Hab. in Montibus Himalayæ; in Mus. Dom. Royle.—*Westwood. M. L. J. July* 1840, *p.* 136.

ELATER CYANOPTERUS, Hope.

Long. lin. 4½., lat. lin. 4½. Cyaneus, antennis fuscis, marginibus thoracis pedibusque rubris Caput nigrum antennis fuscis. Thorax in medio nigro-cyaneus, marginibus lateralibus rubris. Elytra striato-punctata subpubescentia. Pedes rubris. Hab. in Montibus Himalayæ; in Mus. Dom. Royle.—*Westwood. M. L. J. July* 1840, *p.* 136.

RIPIPHORUS APICALIS.

Long. lin. 3., lat. lin. 1. Rufus. thorace pedibusque nigris, elytris flavo-rufis quatuor maculis notatis. Caput atrum ramo antennarum piceo, foliisque nigris. Thorax concolor. Elytra flavo-rufa, basi nigrofasciata, maculis binis fere mediis, apicibusque corporeque infra nigris. Hab in Montibus Himilayæ; in Mus. Dom. Royle.—*Royle's Illustrations of the Botany, &c. of the Himalayan Mountains, Supplementary Part.—Westwood. M. L. J. July* 1840, *p.* 136.

(3456) ENTOMOSTOMATA, De Blainville's name for his second family of his first order, *Siphonobranchiata*, of his first sub-class *Paracephalophora Dioica*, of his second class, *Paracephalophora*, of *Malacozoa*. This family appears to be nearly the same with the genus *Buccinum* of Linnæus and family *Buccinidæ* of other naturalists. The following are the principal Asiatic and Indian genera of this family :—

Cerithium.—Animal very much elongated, the mantle prolonged into a canal at its right side, but without a distinct tube; the foot terminated by a depressed proboscidiform muzzle; tentacula very distant, with large rings, swollen, as it were, in the lower part of their length, and carrying the eyes at the summit of this enlargement. Mouth terminal, in the form of a vertical slit, without any labial tooth, and with a very small tongue furnished with regularly disposed reflexed teeth. A single straight branchia. Shell more or less turriculated, tuberculous; aperture small, oval, oblique; the columellar border very much excavated, callous; the right lip sharp-edged, and dilating a little with age. Operculum horny, oval, rounded, sub-spiral, and striated on its external surface: sunk and bordered on its internal surface.

Cerithium Vertagus.—Locality, Indian Ocean and Moluccas. (Lamarck.)

Cerithium Aluco.—Locality, Indian Ocean and Moluccas. (Lam.)

Genus *Potamides*, Brongniart; *Pyrazus*, De Montfort.

Cerithium palustre.—Locality, coasts of the East Indies, in the salt marshes. (Lam.)

(Genus, *Pirena*, Lam.) *Cerithium Madagascariense.* The number of species of *Cerithia* at present described exceed one hundred.

Planaxis.—Animal unknown. Shell oval, conical, solid, transversely furrowed; aperture oblong; columella flattened and truncated anteriorly, separated from the right border or lip by a sinus: right lip furrowed or rayed within, and thickened by a decurrent callosity at its origin. Operculum horny, oval, delicate, subspiral. Lamarck established this genus for certain small shells approximating closely to the *Phasianellæ*, but differing from them by the truncation of the anterior part of the columella. He only records two species, namely *P. sulcata* and *P. undulata*. M. Rang states that he possesses six well-distinguished species. Woodward, in his 'Manual of the Mollusca,' gives eleven species. They are found in the West Indies, Red Sea, Bourbon, India, the Pacific, and Peru. The *Planaxis* is a littoral shell, and is sometimes found under stones. M. Rang says that he had had occasion to observe the animal at the Isle of France (Mauritius), where the rocks are sometimes covered with them, but, having lost his notes, he is unable to give its principal characters. According to his recollection, the animal differed very little from that of *Phasianella*. M. Deshayes, in his Tables, puts the living species at four.

Subula.—Animal spiral, very much elevated; foot very short and round; head with extremely small triangular tentacula, bearing the eyes at their summit; a long labial proboscis without hooks (crotchets), at the bottom of which is the mouth equally unarmed. Shell without an epidermis, turriculated, and with a pointed spire; whorls smooth, ribanded, bifid; aperture oval, small, deeply notched anteriorly; external lip thin and sharp-edged; internal or columellar lip with an oblique bourrelet at its extremity. Operculum oval, horny, lamellar, and as it were imbricated.

S. maculata (Lam.), *Buocinum maculatum* (Linn). It inhabits the Moluccas and Pacific Ocean, according to Lamarck, who speaks of his possession of a specimen taken on the shores of Owhyhee.

Terebra.—Animal spiral, rather elevated; foot oval, with a transverse anterior furrow and two lateral auricles; head bordered with a small fringe; cylindrical tentacula terminated in a

point, and very distant; eyes but little apparent at the origin and outside of the tentacula; mouth without a proboscis; tube of the respiratory cavity very long. Shell without an epidermis, inclining to oval; spire sharp, not much elevated or subturriculated; aperture large, oval, strongly notched anteriorly; columella with an oblique bourrelet at its extremity. No operculum. (De Blainville.)

Eburna.—Shell oval or elongated, smooth; spire pointed, whorls running together as it were without a marked distinction of suture; aperture inclining to oval, elongated, widened, and deeply notched in front; right lip entire; columella callous posteriorly, umbilicated, subcanaliculated at its external part. They are found in the seas of warm climates. Of the 9 living species Lamarck refers the locality of three to the East Indies and one to South America and perhaps India.

Buccinum.—Shell oval, elongated, with a pointed but moderately-elevated spire; aperture oblong or oval, deeply notched anteriorly, right lip entire, sometimes thick; columella simple or callous; operculum horny, oval, subconcentric; summit but little marked and marginal. The geographical distribution is very wide. Species occur in almost all seas. *B. glaciale* and *B. Sabinii* are noted in the 'Supplement to the Appendix of Captain Parry's First Voyage' as having been met with during the period in which the expedition remained within the arctic circle. The species are very numerous, and have been found at depths ranging from the surface to 17 fathoms. The greater part of the genus is littoral.

Nassa.—Animal very much depressed, with a very large foot, extending beyond the body on all sides, but especially in front, where it is large and angular, whilst posteriorly, it is insensibly narrowed. For the rest like the animal of *Purpura*. Shell globular, oval, or subturriculated; aperture oblong, notched anteriorly; right lip sharp-edged, often plaited within; columellar lip covered with a large callous plate, extending more or less far. Operculum horny. The species of *Nassa* have a world-wide distribution, being found in arctic, tropical, and antarctic seas. They have been found on reefs, coral sand, sand, sandy-mud, and under stones, at depths ranging from the surface to 15 fathoms. About 70 species are known. *N. reticulata* is common on English shores, and called the Dog-Whelk by fishermen.

Harpa.—Animal with a large head, without a proboscis, having the mouth opened below; two anterior tentacula, conical, and very much approximated, carrying the eyes upon an enlargement situated externally a little below the middle; foot large, furnished anteriorly with a sort of heel; siphon rather large and a little elongated; branchial pectinations unequal, two in number; orifice of the oviduct at the entrance of the branchial cavity of the right side, orifice in the deferent canal at the extremity of a very voluminous excitatory organ; vent on the same side. Shell oblong, more or less convex, generally rather delicate, enamelled, furnished with regular longitudinal ribs: spire a little elevated and pointed, the last whorl very large; aperture oval, elongated, widely notched anteriorly, the right lip with an external bourrelet; columella simple, pointed anteriorly. No operculum, according to M. Reynaud. The genus is found in the seas of warm climates, and is more especially abundant at the Mauritius and the neighbouring islands, whence the finest of the more common species and the many-ribbed Harps are procured. The animal is said to be of a rich vermilion red. The fishery is principally carried on at low water with a small rake, to which a net is attached, on sand-banks at night, and at sunrise when the Harps are probably out upon their feed. They have been known to take the bait on the fishing-lines laid for olives (*Oliva*). Messrs. Quoy and Gaimard, and afterwards M. Reynaud state, that the animal of the Harp can sometimes when attacked by an enemy, disembarrass itself of the posterior part of the foot, and completely withdraw itself into the shell. M. Reynaud explains this phenomenon by giving his opinion that the transverse laceration which causes, in the movement of contraction exerted by the animal, the separation of the posterior part of the foot, arises from the resistance which that part, too voluminous to enter the shell after the animal, encounters from the edges of the shell. M. Rang observes, that though no operculum has been found (and the animal appears to have been carefully examined) he does not hesitate to leave the genus among those which are provided with one, because, in the first place, *Harpa* is similarly organised, and, in the next, if deprived of that appendage, it has, at least, the posterior part of the foot to take, in some sort, its place. Authors generally make the number of living species eight, and of these the most precious, though lately greatly depressed in value, is the Many-Ribbed Harp *H. imperialis*). But some of the species are very difficult of definition though others are well marked. The shells when in fine condition are great favourites with collectors, and a drawer of fine Harps in all the freshness of their beauty is indeed a sight worth seeing. Care should be taken to keep them with their mouths downwards and from the sun and light, or their brilliant colours will soon fade. *H. ventriosa.* Locality, Mauritius, &c.

Dolium.—Animal generally resembling that of *Purpura.* Shell delicate, nearly globular, ventricose, furrowed transversely; spire but little elevated, pointed, the last whorl forming nearly the whole of the shell; aperture large, oval, right lip undulated. Columella often twisted; operculum horny. The species are found in the

seas of warm climates, especially those of India. They are also found in Australia and the Pacific. One species, *D. galea*, inhabits the Mediterranean. The species are often found on reefs, some of them are very large. Fourteen seems to be the greatest number hitherto recorded, and Cuvier has separated the species into two sections, namely the Tuns (*Dolium*) and the Partridge Tuns (*Perdix* of De Montfort).

D. galea and *D. perdix*.

Oniscia.—A genus separated from *Cassidaria* by Mr. G. B. Sowerby, and considered by him as having its place next to that genus in the natural system. It differs from *Cassis* in the canal not being suddenly reflected; but Mr. Sowerby states that he has seen *Cassides* which very nearly approach *Oniscia* in the form of the aperture, and in the short scarcely reflected canal. He thinks that the genus is intermediate between *Cassidaria* and *Cassis*. Shell oblong, sub cylindrical, apex generally rather obtuse, spire short, sometimes very short: base rather acuminated; aperture longitudinal, elongated, extending at the base into a very short canal; outer lip thickened, denticulated within, and rather contracted in the centre; inner lip expanded and covered with granules. (Sowerby.) The outside of the shell is tuberculated, cancellated, or ribbed. "Of the animal," says Mr. Sowerby, "we know nothing; but there is every reason for believing it to be related to that of *Cassis*, and that it has an operculum, though we have never seen it." Six living species are recorded, from the West Indies, China, and the Galapagos.

Cassis.—Animal said to resemble generally that of *Purpura*. Shell inclining to oval, convex, with a spire but little projecting, nearly flat; aperture oblique, long and narrow, with the anterior canal very short and recurved towards the back; right lip thick, furnished with an external bourrelet, and toothed within; columellar lip callous, nearly straight, and marked nearly throughout its length with transverse long teeth. Operculum horny, very rudimentary. The species occur principally in very warm latitudes in shallow water: two or three are said to be found in the Mediterranean. The number of living species is about thirty-four. These are divided into two groups by Lamarck; the first consisting of those species whose spire is marked by bourrelets (*C. cornuta*, for example); and the second of those whose spire is without bourrelets (*C. rufa*, for example).

Ricinula.—Animal nearly entirely resembling those of *Buccinum* and *Purpura*. Mantle provided with a tube; foot much wider, and auriculated, as it were anteriorly; head semilunar, with conical tentacula, supporting the eyes at the middle of their external surface; excitatory organ of the male very large, recurved in the branchial cavity. Such is De Blainville's description, who made his observation on 'la Ricinule horrible,' *R. horrida*. Shell oval or sub-globular, thick, beset with points or tubercles, with a very short spire; aperture narrow, long, with a notch (which is sometimes sub-canaliculated) anteriorly; right lip often digitated, externally and toothed within; the left lip callous and toothed or wrinkled. Operculum horny, oval, transverse, concentric. De Blainville describes the elements of the operculum as a little imbricated. There are 29 species of this genus. They are from India, China, the Philippines, Australia, and the Pacific. The species have been found on corals and rocks.

Cancellaria.—Animal said to resemble generally that of *Purpura*. Shell oval or globular, rather convex, reticulated, thick, with a spire slightly elevated and pointed; aperture demioval, notched or sub-canaliculated anteriorly; right lip sharp-edged, striated within; columella nearly straight, with many well-defined plaits. Operculum horny. The species are all exotic, and the inhabitants of warm seas. The localities of the bulk of those known are said by De Blainville to be inhabitants of the Indian and African seas. The species have been found on sandy bottoms, at a depth ranging from 7 to 16 fathoms.

Purpura.—Animal rather elongated, widened in front; head large with a very short proboscis; two tentacula, generally in front and approximated, conical, and supporting the eyes on an enlargement situated at the middle of their external part; mouth below, nearly always hidden by the foot, which is rather large, very much advanced, and bilobated, as it were, anteriorly; branchial pectinations two, unequal; orifice of the oviduct at the entrance of the branchial cavity on the right side; orifice of the deferent canal at the right side of the neck, at the extremity of the exciting organ, which is generally voluminous; vent on the same side. Shell oval, thick, unarmed or tubercular, with a short spire, the last whorl larger than all the others together; aperture very much dilated, of an oval form, terminated anteriorly by an oblique notch; columella flattened, finishing in a point anteriorly; right lip sharp edged, often thickened and furrowed internally, or strongly armed anteriorly with a conical point. Operculum horny, demicircular, the summit posterior. The form is widely distributed, but the number of European species is very small; the greatest development takes place in warm seas, where the species are most abundant, particularly in South America. The larger proportion of the species of this genus are littoral. The true *Purpuræ* have been found at depths ranging from the surface to 25 fathoms, and the division which forms the genus *Monoceros*, generally on rocks, at depths ranging from the surface to 7 fathoms.—*Eng. Cyc.*

Purpura Persica.—East Indian seas.

(3457) **EPIPACTIS**, a genus of Plants belonging to the natural order *Orchidaceæ* or *Orchideæ*, and the tribe *Limodoreæ* or *Arethuseæ*.

It has the perianth patent, the lip interrupted, the basal division concave, the terminal one larger, with two projecting plates at its base above; the stigma nearly square; the rostellum short, terminated by a globose appendage; the anthers terminal, erect, sessile, 2-celled, the cells without septa; the column short; the germen straight on a twisted stalk. There are two species of this genus found wild in Great Britain.—*Eng. Cyc.* Wight gives figures of Epipactis carinata, 1720; Dalhousiæ, 1728; macrostachya, 1722;

(3458) EPIPHYLLUM. This is a division of the Cactus family, containing about 20 known species and varieties. Beautiful plants with flat succulent jointed leaves, from the ends of which the flowers proceed. Grow well in coarse river sand, mixed with pieces of charcoal and a little decayed manure. They require care during the heavy rains, propagated by cuttings, every joint of the leaves will strike in sand. Natives of the tropics —*Riddell.*

(3459) EPIPHYTES are plants found growing upon other vegetables, adhering to their bark, and rooting among the scanty soil that occupies their surface, in which respect they are distinguished from parasitical plants, which, like Mistletoe and the various species of *Loranthus*, strike their abortive roots into the wood, and flourish upon the blood of the individual to which they attach themselves. In this sense of the word, Mosses, Lichens, Ferns, and plants of many other families, are Epiphytes; but as in England, at the present day, the word is principally employed with reference to those *Orchidaceæ* which grow upon trees, it is to plants of that description that we propose to devote the present article. Orchidaceous Epiphytes grow naturally upon trees in the recesses of tropical forests. They establish themselves upon the branches, and either vegetate amidst masses of decayed vegetable and animal matter, or cling by their long succulent grasping roots to the naked branches of trees, from which and the humid atmosphere together they exclusively derive their food. It appears from the testimony of Mr. Henchman that they are never found upon dead erect trees in forests; but if upon dead wood at all, then only upon fallen trunks, which, from their situation near the ground, are constantly damp. Such situations are however said to be by no means favourable to their growth. They also flourish upon rocks and stones in hot and damp climates, and Dr. Wallich found them in all cases growing equally well in Nepaul upon trees and stones, provided the latter had a certain quantity of mould and moss adhering to them. In the botanic garden at Calcutta they are said to be cultivated with success in raised beds of solid brickwork, so contrived as to insure a perfect drainage; the soil being rich vegetable matter mixed with at least two-thirds small pebbles, and covered with a dense layer of moss. A certain

quantity of shade seems, in many cases, essential to them, their natural situation being in forests, or among the branches of growing trees. In Brazil numbers of them occupy damp woods and rich valleys, among vegetation of the most luxuriant description, by which they are embowered. Reinwardt describes others as inhabiting in great abundance those deep shady, gloomy forests, which form the lower zone of vegetation in Java, where the air is heavy and damp with vapours that cannot ascend, and where the thickness of the vegetation is really frightful: where, in short, heat, moisture, and a most extraordinarily deep and rich vegetable soil combine to produce wood of a fungus-like softness and an inconceivable abundance of twining plants and Epiphytes. In those forests more especially where huge fig-trees constitute the principal part of the timber, intermingled with the most tropical forms of vegetation, such as *Sterculiaceæ*, *Sapindaceae*, and *Artocarpaceæ*, tufts of Orchidaceous Plants abound, in company with *Araceae*, *Acanthaceae*, and *Zingiberaceae*. In Nepaul Dr. Wallich states that Orchidaceous Epiphytes grow in company with Ferns; and the thicker the forest, the more stately the trees, the richer and blacker the natural soil, the more profuse the *Orchidaceae* and Ferns upon them. There they flourish by the sides of dripping springs, in deep shady recesses, in inconceivable quantity, and with an astonishing degree of luxuriance. It would however be a great error to suppose that it is only in very shady places that Orchidaceous Epiphytes appear. On the contrary, it is probable that the cases just cited are extreme, and that they more commonly prefer situations where the broken rays of the sun can readily reach them. The general habit of the whole order is extremely local in the majority of cases. Upon comparing the Orchidaceous Plants of Java, of Ceylon, and of the Burmese country, it is quite extraordinary how few species those countries possess in common; and the quantities of species found exclusively in every large collection are a corroboration of the same fact. A high mean temperature throughout the year, and a climate either constantly humid or at least periodically so, are also atmospheric elements eminently favourable to the production of these plants. All those species which simply exist clinging by their roots to the branches of growing trees, and probably others also, must necessarily derive their nourishment in a great measure, if not entirely, from the moisture, in a very elastic state, that surrounds them. And although nature seems in general to have provided for the scantiness of their food by the construction of them with a cuticle only capable of parting by slow degrees with the fluid they receive by their roots, yet it is obviously requisite that they should be so situated as to be within reach of an abundant supply, not only at the time when they are growing, but also at all other

times to a certain extent. Hence we find that the hottest countries, if dry, and the dampest, if cold, are destitute of them; while there is no instance of a country both hot and damp in which they are not plentiful. No country however exhibits in a more striking manner than India the necessity of a hot and damp climate for the production of Orchidaceous Epiphytes. In the Malayan Archipelago, the mean temperature of which is estimated at between 77° and 78° and is very damp, they are found in profusion. In Nepaul it is upon the sides of the lower mountains that they occur, where they vegetate amongst clouds and constant showers; while on the continent of India they are almost unknown, their place being occupied by parasitical *Loranthi*. The traveller finds himself in the morning on the dry plains of Hindustan, where the mean temperature is 80°, and where all the trees are destitute of *Orchidaceæ*; and at noon he is at the foot of the first range of the Nepaulese hills, where every tree teems with that class of plants. There are however places on the continent of India where they are not less numerous than in Nepaul; at the æstuaries of the Ganges, the Brahmaputra, the Irawaddi, and the rivers of Martaban, they exist in vast quantities; but all these stations are excessively damp. In the Botanic Garden at Calcutta, they grow most vigorously during the rainy season, but in the fiercely hot season, which begins in March and lasts till the 10th of June, they perish, notwithstanding all the care they receive. Madagascar and Mauritius offer similar evidence to the same effect. While however these statements are applicable to a very large part of Orchidaceous Epiphytes, there are some striking exceptions that require to be pointed out, both with regard to atmospheric moisture and to the temperature requisite for their production. Mr. Allan Cunningham has shown in the 'Botanical Register,' fol. 1699, that in Australia there are three of these plants which require a very dry atmosphere, and it is probable that others exist in other countries. "These are *Dendrobium æmulum*, Brown, an Epiphyte uniformly found upon the rugged trunk of *Eucalyptus resinifera*, or Iron-Bark, in the open, very dry forest grounds of the older colony at Port Jackson; *Cymbidium canaliculatum*, Brown, which of late years has been observed beyond the tropic both at Moreton Bay and still farther to the southward at Hunter's River, growing upon the principal limbs of several of the *Eucalypti* in the dry, open, shadeless forest. These two Epiphytes flourish most luxuriantly in an extremely dry atmosphere, and flower usually in the summer season in their native wilds, the high temperature of which is oftentimes greatly increased by the blighting hot winds which not unfrequently prevail at that period from the north-west. The third is *Dendrobium undulatum* of Mr. Brown, a handsome species, originally discovered by Sir Joseph Banks at Bustard Bay, and which has been lately found on barren hills naturally clear of timber upon the banks of the Brisbane River at Moreton Bay, where the plant forms tufts on bare rocks exposed to the full heat of the sun, which during nine months of the year is very considerable on that part of the coast." In many cases a much lower temperature than that hitherto spoken of is natural to these plants, and there are some instances where they are naturally accustomed to rigorous weather. In America their favourite station, according to Humboldt, is in the gorges of the Andes of Mexico, New Granada, Quito, and Peru, where the air is mild and humid, and the mean temperature is 63° to 67° Fahr. (17° to 19° Cent.) In these localities they are so abundant that, according to the authors of the 'Flora Peruviana,' above 1000 species might be found in Tarma, Huanuca, and Xauxa alone. It is therefore not surprising that one species, *Epidendrum conopseum*, should advance as far to the northward as the rice climate of Florida, where it grows on the bark of *Magnolia glauca;* nor that others should be found in the damp maritime parts of the government of Buenos Ayres. But it is more remarkable that an *Oncidium nubigenum* should occur at the height of 14,000 feet on the mountains of Peru, and that other species should, upon the authority of M. Descourtilz, be able to bear without difficulty the cold glacial winds of the high sierras of Brazil. The same peculiarities occur in the eastern world. Reinwardt speaks of great quantities of *Orchidaceæ* in the Storax and Laurel woods of Java, growing along with *Nepenthes*, Rhododendrons, Magnolias, and Oaks, in a zone of vegetation whose lower limit is 3000 feet above the sea. *Dendrobium nobile*, *Renanthera coccinea*, and some others, bear the periodical cold of Canton, where it occasionally freezes; *Dendrobium catenatum* and *D. moniliforme* occur in Japan as far north as 37° or 38°, or the parallel of Lisbon, and are periodically subject to a very low temperature; and Dr. Royle met with the deciduous *Coelogynes* and *Dendrobium alpestre* on the Himalaya Mountains, at the height of 7,500 feet, where snow sometimes lies in winter for a week or more. To the southward they not only occur in the latitude of Port Jackson, where the mean temperature does not exceed 66° 6', but even in much higher latitudes. The beautiful little *Gunnia Australis* grows on the branches of shrubs in Emu Bay, in Van Diemen's Land, in about 41° S. lat.; and *Earina mucronata* extends to 45° 45' S. lat., in "the very permanently damp woods which clothe the shores of Dusky Bay in New Zealand," where it was originally observed by Forster in Cook's second voyage, and where it has since been met with by Mr. Cunningham. —*Eng. Cyc.*

(3460) EQUIDÆ, a family of animals, to which the horse belongs. Mr. Bell is of opinion, and, in his 'British Quadrupeds' follows Dr. Gray in considering the Ass as belonging to a distinct genus from the Horse, and he adopts Dr. Gray's family-name *Equidæ*. Mr. Bell makes the following remarks on the character of the Ass and its nearest congeners as compared with those of the Horse, upon which it had been thought necessary to establish them as distinct genera in the family. After admitting the truth of the observation that, in the absence of any knowledge of the original condition of the Horse, the question can only be considered with reference to the characters of a domesticated and probably much altered race, he reminds the reader, nevertheless, that as the distinction upon which the division in question is founded are structural, there is less danger of error than if they had been only those of colour or of general form, and thus proceeds: "The character of the tail is one of the most striking points upon which this distinction rests. In the horse, the whole of this part is covered with long hair, totally concealing its actual form: whilst in the whole of the others, the ass, the zebra, the quagga, the dzigtai, &c., it is only clothed with long hair towards the extremity. The mane of the horse also is long and flowing; that of all the other species is short and upright. In the former animal, the hinder as well as the fore legs are furnished with those warty collosities, which in the others, without exception, are found only on the fore legs. Waiving some other particulars of minor importance, there is one character which, if not in itself to be considered of primary value, is yet interesting, and not unimportant as a collateral distinction: I mean the general tendency of the coloration and marking in the two forms. In the horse's coat there is an obvious disposition to the formation of small round spots of a different shade or hue from that of the ground, and this is the case whether the general colour be black, chesnut, or gray; in the genus *Asinus*, on the contrary, the markings are invariably disposed in stripes. The zebra, the quagga, and the mountain zebra are examples too familiar to require more than this allusion; and in the common ass, not only is the same tendency evinced by the cross-mark on the shoulders, but in the young ass there are frequently observed some obscure darkish bands on the legs. These tendencies to a peculiar character of coloration and marking are well worthy of especial notice in the *Mammalia*, among which will be found numerous instances bearing upon the distinction of approximating forms. In birds and insects it is still more general and striking, and has always attracted the attention of naturalists; but in the present class it has certainly been too much overlooked." Geographical Distribution of the *Equidæ*.—Although the Horse, the Ass, and the Mule, are now spread over the whole face of the civilised earth, and although the Horse is found wild, or rather has reverted to a wild state, in both the New and the Old World, there can be no doubt that the form which we are now considering was originally entirely confined to the latter portion of the globe, where the truly wild species of the family, the Zebra, the Quagga, &c. are still to be found in all their native freedom. And this leads us to consider the time and the place where the Horse was first subdued by the powerful hand of man. Mr. Bell, who appeals to the sacred scriptures in proof that the Horse is of eastern origin, is of opinion, from the same authority, that the Egyptians were probably the first who broke the proud spirit of this noble animal, and reduced it to obedience and servitude. The books of Genesis and Exodus abound with passages which prove that the Horse had been long under the dominion of man at the date of the events then recorded. It was expressly prohibited (Deut, xvii, 16) that the king should multiply horses to himself, or should cause the people to return to Egypt, to the end that he should multiply horses. Solomon however does not seem to have regarded this prohibition, for his stables were filled with these noble animals; he had 40,000 stalls of horses for his chariots, and 12,000 horsemen. (1 Kings, iv. 26.) The grand description in Job (xxxix. 19-25) is familiar to most, but Egypt (1 Kings, x. 28), and not Arabia, seems to have been the source whence Solomon's supplies were obtained. In very early Egyptian monuments the horse is seen in battle, and under circumstances, which denote long subjugation and experienced training. It seems to be quite clear that the wild horses of Tartary are as much the descendants of a domesticated race as the wild horses of America, whose ancestors were introduced by the Spaniards; nor have we any evidence to show the time when the horse existed in a primitive state of nature.

The *Equidæ* form two genera—*Equus* and *Asinus*: the species however freely breed together in confinement, but the produce is almost always, if not always, barren.

Equus has the tail covered with long hair to the base, the fore and hind legs with a wart (sallenders) on the inner side. The fur is dappled, that is, marked with round pale spots, having a dark net-like ground.

Equus Caballus, the Horse, is brown, gray, or black, with roundish pale spots. The following are the synonyms and varieties of this species given by Dr. Gray in the 'Catalogue of the British Museum;'—*Equus antiquorum* (Gesner). *Equus Caballus* (Linnæus); F. Cuvier; Fischer; Gray). *Equus, Equa* (Pliny). Horse (Pennant). Generous Horse (Pennant). Cheval (Buffon; Cuvier). Pferd (Redinger). Ross (Schrank,) The Horse (Youatt). The Tarpan Wild Horse, primeval bay stock (H. Smith). The Andalusian Horse (H. Smith). South American Horse (H.

Smith). The Parameros of Peru (H. Smith). Mexican Horse and Seminole Horse (H. Smith). Feral Horses of America (H. Smith). The Arabian Horse (Bewick; Low; Smith). The Race-Horse (Bewick; Low) English Race Horse (Smith). Hunter (Bewick). The Old Irish Hunter (Low). Black Horse (Bewick). The Old English Black Horse (Low). The Cleveland Bay Horse (Low). The Suffolk Punch (Low). The Clydesdale Breed (Low). Old English Road-Horse (Bewick). Common Cart-Horse (Bewick). Improved Cart-Horse (Bewick). The Barb of Morocco (H. Smith). The Bornou (white) Race of Africa (H. Smith). The Dongola (black) Race (H. Smith). The Turkish Race (H. Smith). The Persian Race (H. Smith). The Toorkee Races (H. Smith). The East Indian Races (H. Smith). The New Holland Horse (H. Smith). The Transylvanian Horse (H. Smith). The Moldavian Horse (H. Smith). The Greek Horse (H. Smith). The Spanish Horse (H. Smith). Cheval d'Islande—var., *Islandicus* (Quoy and Gaim.; Lesson). *Equus Mongolicus* (Lesson). Thibet Horse (Hodgson). Cheval a Port Frisses—*E. frisius* (F. Cuvier). *Equus Caballus frisius* (Lesson). Villous Horse—primeval of the white stock (H. Smith). The White or Gray Horse (H. Smith); Marengo.—'Bonaparte's Arab.' The Crisp-Haired Horse—primeval of the black stock (H. Smith). The Black Horse—the English Draught-Horse (H. Smith). The Dun or Tan Horse (H. Smith). The Decussated Horse, or the Eelback Dun Horse of Ukraine H. Smith). The Myautzee, or the Pied Horse of China (H. Smith). The Bhooteah Ponies (H. Smith). The Pickarrow Ponies (H. Smith). The Yaboos of Affghanistan Ponies (H. Smith). The Hungarian Horse, with slit nostrils (H. Smith). The Common Bashkir Horse (H. Smith). The Morea Ponies (H. Smith). The Swedish and Norwegian Ponies (H. Smith). The Shetland Ponies (H. Smith). The Galloway (H. Smith). The Dartmoor and Exmoor Pony (H. Smith). Sardinian Wild Horse (H. Smith). The Tatto, or the East Indian Pony (H. Smith). Tuttoo, or Mahratta Pony (Sykes); sedulously propagated in the Deccan: much used to transport luggage, and very vicious.—Sykes, Tattoo, or Hack Pony of Calcutta (Hardwick). The Tangun Piebald or Skewbald Horse—*Equus varius* (H. Smith). The Tangum, or Tanghans—primeval Piebald Stock of Thibet (H. Smith). Skewbald of Achin in Sumatra (H. Smith). Tanghan of China (Hodgson). Tangham of Lhassa (Hodgson). Tangham of Gyaunche (Hodgson). Hubstee of Deo Dharma (Hodgson). The Koomrah, or *Equus hippargus* (H. Smith). The Koomrah—*Equus Lalisi* (H. Smith). Hipparyus (Oppian). Boryes (Herodotus). Bourra of Koldagi (Ruppell); Northern Africa: not gregarious. The Kuda or Saran Horse (H. Smith). The Javan Horse (H. Smith). The Tamboro or Birma Horse (H. Smith). Horse with a curled moustache on the upper lip, of Asiatic Russia (Pallas). Horse covered with curled woolly hair, of Asiatic Russia (Falk.; Pallas). Naked Horse of a beautiful form, of Asiatic Russia (Pallas). The Argamaki of Bocharia—a white horse with very close, minute, orbicular, brown spots, of Asiatic Russia (Pallas). It is questionable as to whether there exist at the present day any truly wild horses or descendants of an originally wild stock. Dr. Gray observes that the figures of the Wild Horse, as given by Gmelin, very much resembles the ponies left at liberty on the commons of Cornwall and mountains of Scotland; and it appears very doubtful if these animals are not rather to be considered as domestic horses which have escaped and become deteriorated. Everywhere the horse is recognised as the most useful of the servants of man, and he yields in intelligence to the dog alone. In the earlier ages of the world he seems to have been devoted to the purposes of war or of pleasure, while the ox was our agricultural servant: but his beauty, and strength, and tractability have now connected him, directly or indirectly, with almost all the purposes of life. If he differs in different countries in form and in size it is from the influence of climate and cultivation: but otherwise, from the war-horse, as he is depicted on the freizes of ancient temples, to the stately charger of Holstein and of Spain, or from the fleet and beautiful Arabian to the diminutive Shetlander, there is an evident similarity of form and destination which clearly stamps his common origin. He is naturally and of choice an herbivorous animal. His thin and muscular lips, his firm and compressed mouth, and his sharp incisor teeth are admirably adapted to seize and to crop the grass; and although we know nothing of him in his natural state, yet when he has escaped from the bondage of man, and follows his own propensities, the grass is his chosen food. In his domesticated state however he was destined to live partially or chiefly on other aliment, and that of a much harder kind—the various species of corn; therefore while man and the carnivorous animals can only champ and crush their food, a provision is given to the horse, in the structure of some of the bones of the face, by means of which he can comminute and grind down his food as perfectly as in the best contrived mill. A horse is well broken when he has been taught implicit and cheerful obedience to his rider or driver, and dexterity in the performance of his work. A dogged, sullen, spiritless submission may be enforced by the cruel and brutal usage to which the breaker so frequently has recourse: but that prompt and eager response to the slightest intimation of the rider's will—that manifest aim to anticipate every wish, that gives to the horse so much of his value—must be built on

habitual confidence and attachment. The education of the horse should be that of the child. Pleasure should be as much as possible associated with the early lessons; while firmness, or, if need be, coercion must establish the habit of obedience. No horse should be urged on after he has exhibited unequivocal symptoms of distress, such as a drooping pace, a staggering gait, a heavy bearing on the hand, a rapid inspiration like a hurried sigh, and a peculiar convulsive action of the diaphragm, as though the heart were violently beating against the side. The administration of some cordial medicine, and slow leading to the nearest stable, are the best restoratives at the moment of distress; although the cordial might be absolutely destructive a few hours afterwards, where inflammation had commenced. The watering of the horse is a very important but disregarded portion of his general management. The kind of water has not been sufficiently considered. The difference between what is termed hard and soft water is a circumstance of general observation. The former contains certain saline principles which decompose some bodies, as in the curdling of soap, and prevent the solution of others, as in the making of tea, the boiling of vegetables, and the process of brewing. It is natural to suppose that these different kinds of water would produce somewhat different effects on the animal frame, and such is the fact. Hard water, freshly drawn from the well, will frequently roughen the coat of the horse unaccustomed to it, or cause griping pains, or materially lessen the animal's power of exertion. The racing and the hunting groom are perfectly aware of this; and so is the horse, for he will refuse the purest water from the well if he can obtain access to the running stream, or even the turbid pool. Where there is the power of choice the softer water should undoubtedly be preferred. The temperature of the water is of far more consequence than its hardness. It will rarely harm if taken from the pond or the running stream, but its coldness when recently drawn from the well has often been injurious. It has produced colic, spasm, and even death. It should therefore be exposed for some hours, either in the stable or in some tank. There is often considerable prejudice against the horse being fairly supplied with water. It is supposed to chill him; to injure his wind, or to incapacitate him for hard work. It certainly would do so, if, immediately after drinking his fill, he were galloped hard, but not if he were suffered to quench his thirst more frequently when at rest in the stable. The horse that has free access to water will not drink so much in the course of a day as another who, to cool his parched mouth, swallows as fast as he can, and knows not when to stop. When on a journey a horse may with perfect safety be far more liberally supplied with water than he generally is. An hour before his work commences he should be permitted to drink a couple of quarts. A greater quantity might be probably objected to. He will perform his task far more pleasantly and effectively than with a parched mouth and tormenting thirst. The prejudice both of the hunting and the training groom on this point is cruel as well as injurious. The task or the journey being accomplished, and the horse having breathed a few minutes, another quart, or even two, will be delightfully refreshing to him, and will never do him harm. His corn may then be offered to him, which he will readily take; and before he has eaten the whole of it two or three more quarts of water may be given. Towards the close of the day the speed of the traveller should somewhat abate, and the horse should arrive at his resting-place as dry and as cool as circumstances will permit. If he is hot he must be walked about awhile, or the perspiration will return in the stable. If he is wet he must be carefully rubbed dry. The sooner this is done the better; and after he is clothed, watered, fed, and bedded, he should as soon as possible be left to his repose. In travelling the horse should undergo some degree of training as to the pace, the distance, and the burden. When there has been no preparation, the stages must at first be short, and the pace gentle. For a journey of 300 miles the horse may travel from 20 to 25 miles a day, resting on the Sunday, and doing the work in two stages, at the pace of six miles an hour. This requires a seasoned horse, and number of working hours per day is about four.

Asinus.—The species of this genus have the upper part of the tail covered with short hair, and the lower part covered with longer hair forming a tuft; the fur marked with darker stripes; the fore legs only furnished with hard horny warts in a similar situation to those in the front legs of the horse, but there are none in the lower part of the hinder legs. We shall follow in our arrangement of the species that adopted by Dr. J. E. Gray in the 'British Museum Catalogue.' Colour nearly uniform, with a dark longitudinal dorsal stripe; some have a black stripe across the shoulders.—The Asses of Asia. Ears elongated, acute.—The Tame or Domestic Asses. These animals vary greatly in size and appearance, according to the climate. They are large and smooth-haired in the warmer climates; small and shaggy in the colder countries. It is very doubtful if the Domestic Ass is found in a truly wild state; the asses which have been described as wild appear rather to be domestic animals which have escaped, or mules between the Domestic Ass and the allied wild species; for when caught they, after a short time, submit themselves to man, which is not the case with that Dr. Gray has here considered as the wild kinds. Pallas justly observes, "In extensis Asiæ desertis

primam patriam esse quærendam *Equi feri* et *Onagri* a nomadibus in domesticos usus domatorum, æque ac Hemioni hactenus indomiti." ('Zool. Ross.,' A., i. 255.) This is equally applicable to the African species. *A. vulgaris*, the Domestic Ass. Gray, with a longitudinal dorsal streak and a dark streak across the shoulders; ears elongate; facial line arched; skull with suborbital foramen as in *E. Hemionus*. The following are some of the synonyms of this animal:—*Equus Asinus* (Linn.); *Asinus vulgaris* (Gray); *Equus Asina* (Fleming); *Asinus* (Plin.); Ass (Penn., Bewick); Asne (Buffon); Ane (Cuvier); *Asinus Onager* (Gray, Ronap. 'Index Mam. Eur.'); *Asinus domesticus*, Domestic Ass (H. Smith). *Var.* Without any cross. *Var.* Legs and body more or less banded. Domestic varieties. Gudha of the Mahrattas, very little larger than a good mastiff or Newfoundland dog (Sykes), Domestic Ass of Ispahan (H. Smith). Domestic Ass of Beloochistan (H. Smith). Domestic Ass of Tibet, with a cross-band (Strachey). The Pico of ancient Egypt (H. Smith). Tasandunt of the Shelluhs (H. Smith). The Djaar of Arabia (H. Smith). The Lalisiones, or Wild Ass Colts (H. Smith). Lalisio (Martial). Wild Ass (Lenant; Hoskins). Egyptian Ass (H. Smith). The common Domestic Ass is sometimes of the usual gray colour, without any appearance of the cross. They are sometimes black, and at other times white, rarely skewbald: but this is the common albinism and melanism of domestic animals, and when of these colours the cross is not apparent, or at least sometimes only to be seen when the animal is observed obliquely. Ears moderately short, rounded.—The Wild Asses. *A. Onager*, the Koulan, or Wild Ass. Pale reddish (in winter grayish); dorsal streak black, rather wider over the small of the back. Skull with the infraorbital foramen high up, about one-third the space between the face-line and the back edge of the teeth, far back, being directly over the front end of the cheek ridge and the back edge of the third grinder. This species is the *Asinus sylvestris* (Plin.); *Onager* (Plin.); *E. Asinus Onager* (Schreb.); *Equus Onager* (Brisson); Wild Ass (Bell, Heber); Koulan, or Wild Ass (Penn.); *Equus Hemionus*, Wild Ass of Kutch and the Indus (Sykes); *Asinus Hemionus*, (Gray); *Equus Khur*, Ane Khur (Lesson); Wild Ass, or Gour (Ker Porter); Wild Ass, or Khur, of the Persians; *Onager* (Xenophon); Hemione, or Dziggtai (Lesson); Hymar, or Hamar of Mesopotamia (H. Smith); *Asinus Hamar*, the Hamar (H. Smith); Chamor of the Hebrews. This species inhabits the plains of Mesopotamia, Persia, Kutch; shores of the Indus, Punjab. Mr. Layard says they are abundant in Mesopotamia, and are evidently the Wild Ass of Xenophon. The adults are very difficult to approach within rifle range. The young are sometimes caught alive. The *Khur* inhabits the deserts of Persia in troops, frequenting the hills in summer and the plains in winter. Bishop Heber, as quoted by Colonel H. Smith, says, "No attempt has been made to break the Wild Ass (of Rajpootana) in for riding, nor did it appear that the native ever thought of such. "The Wild Ass of Cutch has the cross-stripe on the shoulder, and differs in colours and heavier proportion from the Wild Ass of Ker Porter." Colonel Smith confounds the domesticated Gudha with the Wild Ass of the Deccan, described by Colonel Sykes, and states on the Colonel's authority that "it is not larger than a mastiff." Eversmann says that many specimens of the Kulan, or *Equus Onager* of Pallas, have been brought to Orenburg from the high steppes between the Caspian and the Aral seas. A good specimen and a skull are in the Museum of the University of Kasan. All these specimens are without the cross-band, and have only the longitudinal dorsal streak. Eversmann considers that the cross-band is either not the character of the species, or perhaps a sexual mark, as he observes that he is not able to discover the specific character which separates the *E. Hemionus* from the *E. Onager*. He further observes that the Mongolians have no particular name for the *E. Onager* of Pallas; the Tartars no name for *E. Hemionus*; the Mongolians called the *E. Hemionus* Deshiggetei, or more properly Tachikitei, meaning long ears, and the Tartars call the *E. Onager* Kulan. Eversmann remarks that Pallas ('N. Nord. Beytr.,' ii. 34) states that the male which M. Hablizl brought from Persia had no cross, but that the female which was shot on the Murecy had one. He proceeds to calculate the length of the ears of these animals, compared with the other measurements of them, and he finds that the ears of the male appear to be considerably (near two inches) shorter in proportion than the ears of the female. ('Bull. Soc. Imp. Nat. Mosc.,' 1840, 57.) The Mule with *Asinus domesticus* has the short smooth fur exactly like the sire, but with a short narrow cross-band on the shoulder; the ears rather longer and black-tipped. *A. Hemionus*, the Kiang. Fur short, smooth, bright-red bay. Legs straw-colour (in winter long, rather woolly grayish, legs whitish), with a broad longitudinal dorsal streak, broadest over the small of the back, without any cross-band on shoulders. Skull: the infraorbital foramen low down, in the centre of the space between the face-line and the base of the teeth, and placed in a line over the back edge of the second grinder, some distance in front of the end of the cheek-ridge. It is the *Mulus Dauricus foecundus* (Messerschm MSS.); *Equus Hemionus* (Pallas); *Equus Hemionus*, Kiang (Ogilby); *Equus Hemionos* (Bodd.); *Asinus Hemionus* (Gray); *Equus Onager* (Eversmann); (?) *Asinus Onager*, Onager Koulan, or Wild Ass of Tartary (H. Smith); *Asinus*

Equioides (Hodgson, Blyth); Wild Ass (Moorcroft); *Equus Kiang* (Moorcroft); *Equus varius* part. (H. Smith); *Asinus polyodon* (Hodgson); Jikta (Shaw); Dshikketee (Penn.); Dgiggetai (Cuvier); Dzigethai (Buffon); Wild Mule, Half Ass, or Fecund Mule (Penn); Wild Ass ('English in Tibet'); Hemionos (Plin.); L'Hemione ('Ency. Method.'); the Ghoor, or Khur (Moorcroft, H. Smith); Wild Esel (Eversmann); the Kiang (H.Smith); Wild Horse (Gerrard). It is found in Tibet. This animal must not be confounded with the domestic asses which are used for burden in Tibet. The male Kiangs are larger and deeper coloured. They live in troops of from eight to ten under the care of a solitary male, where the thermometer is below zero. They live partly on the plains and partly on the mountains; and the lower surface of the hoof varies considerably in form and concavity, perhaps from that circumstance. The Ghoor or Khur of Ladakh, according to Moorcroft, is white about the nose and under the neck, the belly and legs; the back is light bay and the mane dun. They herd in droves, fly at a trot, stop, and look back. Moorcroft saw the Kiangs on the highest summits of Tibet, in their shining summer coats and with their antelope form, scouring along in numbers. Dr. Walker observes—'The Kiang neighs like a horse. The Wild Ass of Cutch brays like an ass. The Kiang has no zebra stripes, neither in the adult nor in the foal.' The Wild Ass of Cutch: transverse zebra stripes are seen on the shoulder in the adult, and still more in the foal; sometimes also the shoulder-cross has been seen. The habitat of the Kiang is on the high tableland of Tibet; of the Wild Ass of Cutch in the sultry plains near the mouth of the Indus. The Kiang of Chinese Tartary greatly exceeds that of the Donkey of Cutch in size; the stallions often stand 14 hands high. Major Charlton and Major Biddulph state that they neigh like a horse. When taken young they will become so tame as to be led about like a horse, and will follow horses almost anywhere. They live in a climate where the temperature is below the freezing point in the middle of the summer; yet they throw off their pale woolly coat during that season, and become bright bay. The Donkey of Cutch is often domesticated in India.

A. Equuleus, the Yo-to tze. Yellowish red-clay colour. Tip of ears, mane, long hairs of tail, well-defined line down the black to middle of tail, and cross-band on the shoulder, three or four cross streaks on knees and hocks, black. It is the *Asinus Equuleus*, the Yo-to-tze (H. Smith); *Asinus Hipparyus*, the Yo-to-tze (H. Smith.) Dr. J. E Gray says, "The specimen described by Colonel H. Smith was alive in a livery stable near Park Lane, London; it was said to have been brought from the Chinese frontier north-east of Calcutta. It was most probably a Kiang, or perhaps a mule between it and the Domestic Ass."

A. Zebra, the Zebra. Hoofs narrow, deeply concave beneath; legs cross-banded.—Living on the Mountains. White; head, body, and legs to the hoofs, black-banded; nose reddish; belly and inside of thighs not banded; tail end blackish. Hoofs narrow, deeply concave beneath. Skull: suborbital foramen as in *E. Hemionus*. It is the *Zebra Indica* (Aldrov.); *Equus Indicus* (Johnston); *Equus Brasiliensis* (Jacob); *Hippotigris* (Dio Cass. 'Hist.' l. 77). *Equus Zebra* (Linn.); *Asinus Zebra* (Gray); Zébre (Buffon); Zebra (Ray; Sebra (Stubb); *Hippotigris campestris* (H. Smith); *Equus montanus* (Burchell); Male Zebra (Edwards); Wild Paard, or Wild Horse, of the Dutch Colonists (Burchell); Wilder Esel (Kolbe); Daow or True Zebra) of the Cape Colonists (Harris); Zeura or Zuora (Lobo); Wild Ass (Kolbe); Var. (?) *Hippotigris Zebra*, the Zebra (H. Smith); *Hippotigris antiquorum*, the Congo Dauw or Zebra of Pigafetta (H. Smith); *Hippotigris antiquorum*, Angola Dauw (H. Smith). It is a native of the mountains of South Africa. Hybrids between the species of *Equidæ* are numerous. The offspring of the male Ass (*Asinus vulgaris*) and a Mare is called a Mule, which has generally the form, in a great degree, of the dam, and the head, ears, and tail of the sire. The Spanish mules are well known for their symmetry, sureness of foot, and unwearied activity, and are the produce of a breed of asses far beyond those of Great Britain in stature, shape, and general appearance. The hinny, which is the offspring of the Horse and the female Ass, is altogether inferior, and is less esteemed than the Mule. Hybrids have also been produced from the Horse and the Ass breeding with the Zebra or the Quagga. Two mules that belong to the Zoological Society are the offspring of the Ass and the Zebra. The Earl of Morton bred a female hybrid from a fine Male Quagga and a mare of nearly pure (seven-eights) Arabian blood. Remains of *Equidae* occur abundantly in the third period of the Tertiary series (Pliocene of Lyell), in the fresh-water deposits, in what is called Diluvial Detritus, in superficial gravels, sands, and clays, in the Ossiferous Caverns, in the Osseous Breccia, in the Epplesheim Sand &c. Bones of the Horse occurred, but not abundantly among the remains found by Captain Cautley lying on the slopes among the ruins of fallen cliffs, and partly in situ in the Sandstone in the Sewalik Mountains at the southern foot of the Himalayas, between the Sutlej and the Ganges. Several species have been recorded, but we must not forget the opinion of Cuvier, who thought there were not sufficient data for specific distinctions. He informs us that he had carefully compared the skeletons of many varieties of horses, those of the Mule, the Ass, the

Zebra, and the Quagga, and he never could find a character sufficiently fixed to enable him to pronounce on a species from an isolated bone. Size, he remarks, furnishes but incomplete means of distinction: horses and asses vary much in this particular, from their state of domestication; and he adds, that though he had not yet procured the skeleton of a Dshikketee, he doubted not its resemblance to that of the other species as much as they resembled each other in the same particular. He therefore seems to be borne out in his opinion that comparative anatomy cannot solve the question whether the horse whose remains are found in a fossil state resembled the horses of the present day. The fossil species recorded by authors are *Equus fossilis* (*E. Adamiticus* of Schlotheim); *E.* (*Caballus*) *primigenius*; *E.* (*Mulus*) *primigenius*; *E.* (*Asinus*) *primigenius*. Professor Owen, in his 'British Fossil Mammals,' has described three species of *Equidæ*—*Equus fossilis*, *E. plicidens*, and *Asinus fossilis*. Their remains were all found in the Tertiary Formations of England. He thus concludes his remarks on the Fossil *Equidæ*:—"In reviewing the general position and distribution of the fossil remains of the genus *Equus*, we find that this very remarkable and useful form of Pachyderm first made its appearance with the Rhinoceros during the Miocene periods of geology. From the peculiar and well marked specific distinction of the primogenial or slender-legged horses (*Hippotherium*), which ranged from Central Europe to the then rising chain of the Himalaya Mountains, it is most probable that they would have been as little available for the service of civilised man as is the Zebra or the Wild Ass (*Equus Hemionus*) of the present day; and we can as little infer the docility of the later or Pliocene species, *E. plicidens* and *E. fossilis*, the only ones hitherto detected in Britain, from any character deducible from their known fossil remains. There are many specimens however that cannot be satisfactory distinguished from the corresponding parts of the existing species, *E. caballus*, which with the Wild Ass may be the sole existing survivors of the numerous representatives of the genus *Equus* in the Europeo-Asiatic continent during the Pliocene period. The species of *Equus* which existed during that geological period in both North and South America appears to have been blotted out of the Fauna of those continents before the introduction of man. The aborigines whom the Spanish conquistadors found in possession of Peru and Mexico had no tradition or hieroglyphic indicative of such a quadruped; and the horses that the invaders had imported from Europe were viewed with astonishment and alarm. "The researches of Mr. Darwin and Dr. Lund have however indisputably proved that the genus *Equus* was represented during the Pliocene period by a species (*E. curvidens*) which is shown to be distinct from the European fossil and the existing species. Fossil remains of the Horse have likewise been discovered in North America. The geographical range of the genus *Equus* at the Pliocene period was thus more extensive than that of the Rhinoceros, of which both the extinct and existing species are confined to the continents of the Old World of geography. The Horse, in its ancient distribution over both hemispheres of the globe, resembles the *Mastodon*, and appears to have become extinct in North America at the same time with the *M. giganteus*, and in South America with the *M. Andium*, and the *Megatherium*. Well may Mr. Darwin say, 'It is a marvellous event in the history of animals that a native kind should have disappeared, to be succeeded in after ages by the countless herds introduced with the Spanish colonist.'"—*Eng. Cyc.*

(3461) ERANTHEMUM CINNABARINUM. Cinnabar coloured Eranthemum. On the sides of some of the limestone cliffs in Amherst Province this bright orange-scarlet flower is often seen; and it would be quite an addition to gardens, in which it has not yet found a place, although it is represented in Wallich's rare Indian plants.—*Mason.*

(3462) ERANTHEMUM. The varieties cultivated in Madras are for the most part indigenous, E. pulchellum and E. montanum, grow in almost any soil and situation. E. bicolor requires shade and plenty of water: only fit for borders and flower beds, propagated by cuttings during the rains.—*Jaffrey.*

(3463) ERANTHEMUM PULCHELLUM. Nervose Eranthemum.

Gool-shan, Hind.

Found under the shade of trees in the Kotah jungles.—*Gen. Med. Top. page* 173.

(3464) ERIA OBESA. A species of Eria is one of the most abundant of Tenasserim epiphytes, but the flowers are small, and have little to recommend them.—*Mason.* Wight gives figures of Eria pauciflora, 1636; polystachya, 1634-35; pubescens, 1634-35; and reticosa, 1637.

(3465) ERINOCARPUS NIMMONII. Tiliaceæ. Jungle Bendy. A middle sized tree; flowers yellow in terminal panicles, appear in September and October. Fruit triangular, covered with bristles; angles somewhat winged, has a pleasing fragrance.—*Jaffrey.*

(3466) ERIOBOTRYA JAPONICA. Pomaceæ. The Loquat yang-ma, Chinese. This tree is now introduced all over the Deccan, and bears fruit twice in the year. It is highly esteemed both for deserts and preserves. It is a native of Japan, but grows in great perfection in New South Wales. The finest fruit is produced at the second crop, at the end of the cold season, and requires protection day and night; from

birds in the former, and flying foxes in the latter. The fruit is a yellow color, with thin skin, a sweet acid pulp, one or two seeds in the centre —sometimes more. The seeds grow easily. Proper attention does not seem to have been given to this fruit, as it appears to be capable of great improvement.—*Riddell.* In Ajmere, it is cultivated in gardens but does not thrive well.—*Gen. Med Top. p.* 195. It is very common in China and is often mentioned by Fortune, for instance, at one place, he found, (*Eriobotrya japonica*), the loquat or young-mai, (*Myrica, Sp*), peaches, plums, and oranges.—*Fortune's Tea Districts, p.* 30; and at another, Other fruits—such as the loquat (*Eriobotrya japonica*), the Chinese gooseberry (*Averrhoa Carambola*), the wangpee (*Cookia punctata*), and the longan and leechee.—*Tea Districts, page* 7.

(3467) ERIODENDRON, a genus of plants belonging to the natural order *Sterculiaceae*, known by the name of Wool or Cotton-Trees. The wool-trees are large trees, with a spongy wood which is used for little besides making canoes in the districts where they grow. The leaves are palmate, and the flowers are large, red, white, or scarlet, and rising singly or in clusters from the sides or tops of the branches. The calyx is naked, irregularly 5-lobed, with the lobes usually twin; the petals are 5-joined together, and are connected with the column of the stamens at the base. The filaments of the stamens are joined together into a short tube at the base, and divided into 5 bundles at the apex; these bundles are filiform, and each bears 1, 2, or 3 linear or anfractuous anthers at the apex, which have the appearance of one anther, and are either adnate or versatile. The stigma is 5- or 6-cleft. There are 6 species of *Eriodendron*, 5 of which are natives of America, and 1 of Asia and Africa.—*Eng. Cyc.*

(3468) ERIODENDRON ANFRACTUOSUM. *Bombaceae*, Icon. 400. (DeCand.), Cotton tree. *Syn.* Bombax pentandrum, L.

Elavum marum, Tam. | Suffed simul, Hind.

E. anfractuosum has versatile anfractuous anthers; leaves with 5, 7, or 8 entire cuspidate leaflets, glaucous beneath and a usually prickly trunk. This tree attains a height of 150 feet or more. There are two varieties described, the one growing in the East Indies and the other in Guinea. They differ chiefly in the colour of their flowers. The Indian species, *E a. Indicum*, has flowers yellowish inside and white outside; whilst the Guinea species, *E. a. Africanum*, has large crimson flowers. In Guinea this tree is one of the largest and tallest of the forest-trees and the trunk is employed for making the largest-sized canoes.—*Eng. Cyc.* It is an elegant tree, common on the Coromandel Coast; the leaves fall during the cold season, and the blossoms appear in February before the leaves. The trunk is perfectly straight, the seeds numerous, smooth, black, and enveloped in very fine soft silky wool. The gum is termed *Huttian ke goond*, and is given in solution with spices in bowel complaints.—*O'Shaughnessy, page* 227. This produces a light wood, employed by the toy-makers. It is likewise used for making rafts.—*Ainslie's Mat. Med, page* 208. Dr. Mc.Clelland mentions that in the Tenasserim Provinces, *Bombax pentandrum*, *B. heterophyllum* and *Cochlospermum gossypium*, all afford a soft down, which is attached to the seeds and which the Burmese collect for stuffing pillows. At the Madras Exhibition of 1857, a very powerful bast was exhibited by Mr. Jaffrey, from the *B. pentandrum*, now Eriodendron anfractuosum. This large tree grows in many parts of the Deccan.—*Riddell.*

(3469) ERIOLÆNA TILIIFOLIA.

Let pan, Burm.

Grows plentifully throughout the Pegu and Tounghoo districts, attaining a height of fifty feet, with a girth, of seven or eight feet sometimes, but usually about six feet. It is a strong tough timber, similar in its properties to Kydia. Wood, white-coloured, adapted to every purpose of house-building.—*McClelland.*

(3470) ERIOPHORUM, the systematic name of the sedge-like Plant which is called in Great Britain Wild Cotton, or Cotton-Grass, in consequence of the long cottony tufts which wave upon its stalks in marshy and sedgy heaths and wastes in all parts of this country. The appearance is owing to the hypogynous scales, which in this glumaceous genus, represent the calyx, being extended into long numerous white hairs, which project far beyond the scales of the flower-head. It is not a little curious that while, in most of the species, these hairs are indefinitely numerous they should in one, *E. alpinum* be reduced to the regular number, six, which is the general proportion of floral envelopes belongiug to Endogens. Professor Dunth enumerates twelve species, all inhabiting the colder parts of the northern hemisphere. The silky or cottony substance which clothes the fruit of the species of this genus is made into paper and the wicks of candles: it is also used for stuffing pillows, &c. The leaves of *E. comosum* are in the Himalayas extensively employed in the manufacture of ropes.—*Eng. Cyc.*

(3471) ERIOPHORUM CANNABINUM. Royle. Cotton-grass.

Bhabur, Hind.

All who have scrambled up the steeps of the Himalayas will remember the great support they derived from the toughness of the tufts of the *bhabhur*, which grows commonly there, as well in low valleys as at considerable elevations. It is every where employed by the mountaineers in making ropes as well as a rough strong twine well suited for all ordinary purposes. Specimens

of the dried leaves, made up into bundles about three feet long, were sent to the Exhibition of 1851, from Bheer-bhoom.—*Royle, Fib. pl. p.* 33. Its seeds are clothed at their base with a silky or cotton like substance, with which pillows are stuffed and wicks of candles, as well as paper made.—*Royle, Fib. Plants.*

(3472) ERODIUM GRUINUM. GERANICEÆ. So named from Geranos, a Crane. They are mostly all from the Cape of Good Hope. Most of the flowers are devoid of odour, and those which are particularly so are the most beautiful, whereas those again whose petals are the least showy, diffuse towards the evening and during the night a most powerful perfume; this is particularly the case with such as have white petals spotted with red. The almost innumerable varieties now produced in England have originated by hybridization, and to enumerate them all here is unnecessary. "The flowers of all the kinds are borne in umbels on a peduncle, which in the stemless kinds arises from the centre of the source of the leaves, and in the shrubby kinds from the axil of almost all of the upper leaves. The number of the flowers borne in an umbel is various in different kinds, and greatest in those of the horse-leafed group." The commonest sorts cultivated in gardens are the deep scarlet, light pink, and ivy leafed. The latter has a strong perfume, and scents the fingers if only slightly touched. The ordinary mode of propagation is by cuttings and seed. Almost all the varieties produce seed, which will immediately grow if sown, and should be transplanted as soon as two or three perfect leaves are formed. The cuttings grow most readily, and should be taken off at the joints when the wood is assuming a brown appearance, and beginning to ripen. The fibrous-rooted herbaceous sorts may be multiplied by dividing the roots. As all the species are rapid growers, they require pruning, and to be occasionally changed into fresh pots. They require a light rich soil of loam and old well rotted stable manure, or else leaf mould and sand: the cuttings when put down must be removed for a time to a shady spot, and the earth kept continually moist. I must particularly caution against cutting the plants during the rains, as the whole plant suffers by the ends of the shoots decaying; neither should they be exposed during the hot winds, especially the soft velvet-leafed varieties.—*Riddell.*

(3473) ERVIE, Urvie; Caladium Esculentum. This is a small bulbous root sown from March to July, in rows or beds, mostly along a water course where ginger is planted. It requires much water, and takes from six to seven months to ripen. When boiled and then roasted it is very wholesome and somewhat resembles a yam in taste: the natives also put it into curries.

(3474) ERVUM, a genus of Plants belonging to the natural order *Leguminosæ* and tribe *Vicieæ*. It is known by a 5-cleft calyx. with linear acute segments, about equal in length to the corolla; glabrous stigma; an oblong 24-seeded legume. Most of the species of this genus are weeds, two of which, the *E. hirsutum* and *E. tetraspermum*, are found in Great Britain. The former is called Tine-Tare, and is a great pest in corn-fields. —*Eng. Cyc.*

(3475) ERVUM LENS. Lin.

Mussoor, HIND. | Mussoor purpoo, TAM.
Masur, GUZ.

Mussoor is the Mahratta, as well as the Hindoostanee and Sanscrit name of a valuable pulse, much cultivated in the higher provinces of India, *Ainslie, p.* 242. *Ervum Lens* has branched stems; oblong nearly glabrous leaflets, usually eight in number; the stipules lanceolate and ciliated; the peduncles 23-flowered, about equal in length to the leaves; the legumes short, broad, finely reticulated; seeds two, compressed. It is a native of corn-fields on the continent of Europe. Lentils are not much eaten in Britain, but they are consumed in considerable quantities in France, Germany, and Italy. The Lentil is one of the oldest leguminous plants used as food of which we have any record. Ever since the time of Esau they have been eaten in the East. In Egypt and Syria they are parched in a frying-pan and sold in the shops, and considered by the natives as the best food for those who are on long journeys. The Lentil is still cultivated in England. There are three varieties known in France and Germany: the small brown, which is the lightest flavoured and the best for soups: the yellowish, which is a little larger and the next best; and the Lentil of Provence, which is almost as large as a pea, with luxuriant straw, and it might be cultivated as food for cattle. In its cultivation the Lentil requires a dry warm soil; it should be sown later than the pea at the rate of a bushel or a bushel and a half to the acre. It ripens earlier than the pea, and requires the same treatment and harvesting. The produce of the Lentil in grain is about a fourth less than that of the tare, and the straw is not more than a third as much. The straw is however considered very nourishing, and is used for feeding calves and lambs. Lentils, like all other leguminous fruits, contain a large quantity of nitrogenized matters. Einhoff found that 3840 parts of lentils contained 1260 parts of starch and 1433 parts of a matter analogous to animal matter. In a late analysis made by Dr. Playfair for the Royal Agricultural Society he found that 100 parts of lentils contained 33 parts of albumen or gluten and 48 parts of starch, &c.; whilst the same quantity of peas contained 29 parts of albumen, and of beans 31 parts. If the theory of nutrition propounded by Professor Liebeg in his late work on 'Animal Chemistry' be correct, then lentils constitute one of the most highly

nutritious foods in nature.—*Eng. Cyc.* It is said to be the flour of this plant which is so highly extolled as a farinaceous aliment. By a slight change, Ervum lens became the Ervalenta, and another person, with another little change, sold the same article as Revalenta adding the term Arabica to note its Asiatic origin. On analysis Warton's Ervalenta was found to consist of a mixture of the French or German lentil, ground and reduced to powder, including portions of the shells or husk, and of a substance very closely resembling in its microscopic characters maize or Indian-corn meal. The French lentil, either whole or ground, is of a yellowish colour, and has the taste of peas. It has been stated that the farina of a grass called "Dari," "Durra," &c., has been discovered in either Ervalenta or Revalenta. "Dari, I suspect means Durra, also spelt Doura, Dorv, &c. It is a corn used by the Arabs, and is cultivated in the South of Europe. It is the Holcus durra sativus of Forskal, the Sorghum vulgare of some other writers. "Its meal is said to resemble that of Indian corn. Now it deserves notice, that a German miscroscopist recently stated that he found the meal of Indian corn in ervalenta, or revalenta, I forget which. Did he mistake it for the Sorghum?" The article sold in bottles at 1s per lb., and recommended to be used in cases of obstinate constipation with the Ervalenta, appears to be nothing more than treacle, the name "Melasse" being derived from the word molasses. On analysis of Du Barry and Co.'s Revalenta Arabica, it was found to consist, like the first, of a mixture of the red or Arabian lentil and barley-flour, sweetened with sugar. A third sample consisted of the Arabian lentil and barley-flour, with the addition of saline matter, principally chloride of sodium or common salt; it also possessed a peculiar taste, as though flavored with celery-seed. While Warton's Ervalenta is of a yellowish colour, Du Barry's Revalenta is of a pink or rosy hue, this arises from the different species of lentil employed, the German being yellow, and the Arabian lentil of a red colour. Lentils belong to the natural family of plants, Leguminosæ, which includes the several kinds of beans and peas; they resemble, to a very great extent, in colour, structure, taste, and properties, the common pea; so great, indeed, is the similarity in organization, that it is difficult to discriminate between them, even by the aid of the microscope. Lentils, peas, beans, &c., all contain a considerable amount of nitrogenized matter, in the form of Legumine. When taken as an article of diet, they are found by most to be somewhat difficult of digestion, to occasion distention and flatulency, and to be slightly aperient. These properties and effects are so similar in the case of each, that it is almost impossible to draw any decided line of demarcation between them. As the cost of most of the prepared lentil powders—viz, 2s. 9d. per pound—forms a very serious obstacle to their use, supposing that in any respect it is desirable that they should be more generally consumed, we have framed the two following receipts, whereby a considerable saving of expense may be effected:—

1st Receipt.

Red or Arabian lentil-flour.....	2 lbs.
Barley-flour,.....	1 lb.
Salt,.....	3 oz.

Mix into a uniform powder.

The red lentil may be obtained of almost every corn chandler, at about 4d. per quart; the cost of a pound of this Ervalenta would be about 2d. per pound; and it is perfectly clear, from the analysis which we have given above, that whatever may be the advantages possessed by the much-vaunted Ervalentas, Revalentas, &c., the new article must contain them all.

2nd Receipt.

Pea-flour,.....	2 lbs.
Indian corn flour,.....	1 lb.
Salt,.....	3 oz.

Mix as before.

Being satisfied that lentils and peas do not differ in their properties to any great extent, we have devised the above receipt to meet those cases in which any difficulty may be met with in procuring the red lentil, which however is now very commonly kept by corn chandlers. Whatever may be the results of the experience of others as to the advantages derived from the use of lentil-powder, we ourselves are unable to say very much in its favor. We recently partook of some of Du Barry's Revalenta Arabica, and found the flatulent effects so unpleasant that we should not readily be induced to repeat the experiment. Hassall.—*Food and its adult. p.* 241.

(3476) ESCHSCHOLTZIA. PAPAVERACEÆ. This is a very beautiful little flower, of a deep yellow orange colour, very delicate. It blossoms only in the cold weather, and requires care in transplanting:—not more than one plant in a pot, which should be deep—the root being long, and tapering: grown from seed.—*Riddell.*

(3477) ESPARTO, SPARTO. A plant (*Stipa tenacissima*), growing in Spain and Africa; anciently held in esteem for the manufacture of cordage, but now nearly in disuse, except in the countries of its production, where it is made into cables, cordage, shoes, mats, baskets, nets, &c. It is found wild in places so barren as scarcely to produce any other spontaneous vegetation. At the present time it is used by the Spaniards for various purposes, especially in the manufacture of a kind of shoe, or rather sandal, called *alpergates*. *Waterston.*—*Faulkner.*

(3478) ESSENTIAL OR VOLATILE OILS occur in the stems, leaves, flowers and fruit of

many odoriferous plants and are procured by distillation along with water. They are called essences and contain the concentrated odour of the plant. They usually exist ready formed, but occasionally they are obtained by a kind of fermentation, as oil of bitter almonds and oil of mustard. Some of them consist of carbon and hydrogen, only, as oil of turpentine from Juniperus communis; Oil of savine from Juniperus Sabini; Oil of lemons and oranges from the rind of the fruit; and oil of neroli from Orange flowers. A second set contain oxygen in addition, as oil of cinnamon from Cinnamomum verum; Otto or attar of roses from various species of rose, especially Rosa centifolia: oil of cloves from Caryophyllus aromaticus. Those principally obtained from tropical shrubs and plants are citronella oil of oranges and lemons, from the rind of the fruit, oil of cinnamon and cloves, croton oil &c. The oil of Sandal or Sanders wood (Santalum album) grown on the Malabar coast is much esteemed as a perfume. Keora oil from Pandanus odoratissimus in Bengal. Oil of spikenard so highly prized on account of its perfume by the ancients may be procured in Sagur, Nepaul, and the mountains of the Himalaya. 956 lbs. of essential oils were imported into Hull in 1850. There were exported from Ceylon in 1842, 902 cases: in 1843, 138: in 1844, 20: in 1845, 25 cases of essential oils and in the last two years as follows:—

	1852 Cases.	1851 Cases.
Cinnamon oil, ...	17	23
Citronella oil, ...	110	87
Essential oil, ...	72	35

Of Chemical, essential, and perfumed oils imported into England from France the quantity is about 35,000 lbs. annually worth £10,000. The duty is 1s. per lb., we also imported from France in 1851, 9,596, cwt. of oil or spirit of turpentine worth £14,197. on which a duty of 5s. 3d. per cwt. is levied.—*Simmonds' Coml. Products, page* 565.

(3479) ESTRICH, Estridge.

Duvet d' autruche, Fr. | Struthionum plumæ molliores, Lat.
Penna Matta di strozzo, It.

The fine soft down which lies immediately under the feathers of the ostrich. The finer kind is occasionally used as a substitute for beaver in the manufacture of hats; the coarser is sometimes made into a species of cloth. Localities, the Levant, Italy, and other parts of the Mediterranean.—*Faulkner.*

(3480) ERYTHRINA, a genus of Tropical Trees and Tuberous Herbs belonging to the natural order *Leguminosæ*. The species have ternate leaves and clusters of very large long flowers, which are usually of the brightest-red; whence the species have gained the name of Coral-Trees. Frequently their stem is defended by stiff prickles. They occur in the warmer parts of the Old and New World. An Indian species, *E. monosperma*, is said to yield gum-lac. De Candolle mentions 32 species; of which *E. Crista Galli* is commonly cultivated in green houses for the sake of its splendid blossoms.—*Eng. Cyc.*

(3481) ERYTHRINA. The Mountain coral tree. A fine looking timber tree of this genus producing a reddish wood, is not uncommon in the interior of Tenasserim. The Karens select the tree in preference to all others on which to train their betel vines.—*Mason.*

(3482) ERYTHRINA INDICA, Indian Coral tree. Willd. Colebr 83 Hort. Mal. Mourucou. 6. p. 13 and 7.

Moorkoo marum. Tam. | Modooga Vriksha, Can.
Badida chettoo, Tel. | Palita Manda, Beng.
Pangra, Hind.

This is also sometimes called by the Tamuls, Kaliana Morkay. It is the wood commonly used by the sect of Mootchie men, for making light boxes, scabbards, children's play things &c. It is likewise employed in making rafts, and fisherman's floats, and is hollowed out and made into canoes. The wood used for this purpose in upper Hindoostan is the Bombax ceiba.—*Ains. Mat. Med. p.* 208. It is a pretty large tree common over India, and the islands, flowering at the beginning of the hot season. Seeds ripening in June and July. This tree is employed in many parts of India to support the black pepper vine. What seems to render these trees very proper for this purpose is their quick growth (from cuttings), their firm permanent though smooth bark, which never peels off and gives firm hold to the roots of the vine, and lastly, they are full of leaves and very shady during the hottest months of the year which shelters the vine from the intense heat of the sun and keeps the ground moist. As soon as the hottest weather is over, the leaves drop and expose the vines to the sun and weather during the cool season. Roxb.—*Rohde. M.S.S.*

(3483) ERYTHRINA SUBEROSA.

Mooni or Modooga, Tel. | Mooni Motaga, Tam.

A native of the Circars growing in every soil and situation, leaves deciduous during the cold season. Flowers in February and March, soon after which the leaves appear; the trunk is generally erect from eight to twelve feet to the branches.—*Rohde, M.S.S.* This tree is less common than the Indica, the trunk is covered with deeply cracked corky bark, deciduous in the cold season, flowers in February and March.

(3484) ERYTHRINA SUBLOBATA.

Badadoomoo, Tam. | Badeda, Tel.

A tree, frequently of great size, branches spreading and numerous, trunk without prickles.—*Jaffrey.* It is native of the inland mountains of the Circars. The wood of all these species is remark-

ably light, soft and spongy, it is much employed by the Moochies who make trunks, toys, and other things that are to be varnished, the wood retaining its priming or under coat of paint better almost than any other wood, it is not liable to warp, contract or split. The Moochies at Condapilly and Nursapore are famed for their art in forming and varnishing this wood for Toys &c. It is planted by the Tamil people about their temples. In Bengal the leaves fall during the cold season in February, when destitute of foliage, the blossoms appear and soon afterwards the leaves: the seed ripens in May, the trunk is perfectly straight in large trees five or six feet in circumference, tapering regularly, seeds are enveloped in fine, soft, or silky wool, adhering slightly to it.—*Rohde, M.S.S.*

(3485) ERYTHRINUS, a genus of Tropical Fishes belonging to the family *Clupeidae.*—*Eng. Cyc.*

(3486) ERYTHROXYLEÆ, a group of Exogenous Plants, considered by some as a distinct natural order; by others as a subordinate division of *Malpighiaceae*. They have alternate stipulate leaves and small pallid flowers. The calyx is 5-lobed: the petals are 5, with a remarkable appendage at their base, which afford one of the marks of distinction between *Erythroxyleae* and *Malpighiaceae*: the stamens are 10, slightly monadelphous. The ovary is superior, 3-celled, with 3 styles, and solitary pendulous ovules. The fruit is drupaceous. Some of the species of *Erythroxylon*, the only genus, have a bright-red wood, occasionally used for dyeing; but the most extraordinary species is the *Erythroxylon Coca*, an account of the inebriating effects of which is given under Coca.—*Eng. Cyc.*

(3487) ERYTHROXYLON AREOLATUM. Deo-dar. Deva-Daree. Areolated Erythroxylon Lin.

Devadaree, Tel.	Dawadar, Duk.
Deo dharee, Hind.	Shujrooljin, Arab.
Devatharum, Tam.	Devadaroo, Sans.

The young leaves and tender shoots of this tree are supposed to be of a cooling nature and when bruised and mixed with a certain portion of Gingilie Oil form a refreshing liniment for the head. The wood of this small tree is so fragrant that the inhabitants of Mysore use it instead of sandal wood.—*Ains. Mat. Med. p.* 212. Under the Tamil name of *Davahdarum-keeray*, the tender leaves of this tree are used as greens but mostly by the country people; the flowers are very small of a yellowish green color. —*Jaffrey.*

(3488) ERYNGIUM, a genus of Plants belonging to the natural order *Umbelliferae*, and the tribe *Sanicolae*. It has a calyx of five leafy teeth, the petals erect, oblong, with a long inflexed point; the fruit obovate, covered with chaffy scales without ridges or vittæ. The species are usually perennial spiny herbs, with the flowers congregated into oblong or roundish dense heads. Nearly 100 species of this genus have been described. They are found in greatest numbers in America, but many are inhabitants of Asia, Africa, and Europe. They are most of them handsome and ornamental plants, and worthy of cultivation. They will grow freely in any common garden soil, but the lighter or more sandy the soil the better they will grow. Some of the species require the greenhouse or frame, and they should be grown in pots. They may be propagated by dividing the roots, or by sowing the seed. (Don, *Dichlamydeous Plants*; Babington, *Manual of British Botany*; Lindley, *Flora Medica.*)—*Eng. Cyc.*

(3489) ERYNGIUM CAMPESTRE vegetates in Cashmere and Cabul as well as in Europe, but it is not officinal any where.—*Honigberger, p.* 274.

(3490) ERYNGIUM GIGANTEUM, of this extensive genus of plants, some are ornamental and well adapted for the flower border, the colours are blue, light blue, white, light white, and green, they thrive best in a sandy soil.—*Riddell.*

(3491) ERYSIMUM PERFOLIATUM, is cultivated in Japan for its oil seeds.—*O'Shaughnessy, p.* 187.

(3492) ERYSIMUM PEROWSKIANUM. *Cruciferæ*. This is the only one of a numerous genus at all ornamental, it thrives in any soil, the flowers are dark orange colour.—*Riddell.*

(3493) EUCALYPTUS, a genus of Australian Plants, consisting of lofty trees, with a volatile aromatic oily secretion in their leaves, and a large quantity of astringent resinous matter in their bark. They belong to the alternate-leaved division of *Myrtaceae*, and are generically known among these plants by their corolla being absent, and the limb of their calyx consolidated into a hemispherical or conical cap, which is thrown off when the stamens expand. This genus occurs in the Malayan Archipelago, but is chiefly Australian, and, together with the leafless Acacias, gives a most remarkable character to the scenery. The species exist in great profusion, and form the largest trees in the forests of that part of the world. A modern writer upon the plants of Van Diemen's Land says that *Eucalyptus* seems as if it had taken undisturbed possession of those Australian regions, clothing as it does with a stupendous mantle the surface both of Van Diemen's Land and Australia; while the intermixture of other plants, which this lordly tribe permits, is, compared with its own great extent, but small and partial. Wherever you go, one species or other is constantly before you. No trees in the world so constantly or

rapidly arrive at gigantic dimensions; they often become hollow, and are then used by the traveller as roomy places of shelter at night. Frazer found a hollow *Eucalyptus* at Moreton Bay, used by the natives as a cemetery. Even at Swan River, where, according to the report of Frazer, the species are stunted, they also attain a huge size. *E. calophylla* attains a height of 150 feet, and a girth of from 25 to 50 feet is not an uncommon dimension of these trees. Their timber is represented as highly useful for domestic and other purposes; being so soft at first as to render the felling, splitting, and sawing up of the tree, when green, a very easy process, and when thoroughly dry becoming as hard as oak. Upon the whole this genus must be considered the most important that Australia produces. As it occurs so far to the south as Van Diemen's Land it is almost certain that it might be naturalised in Devonshire, Cornwall, and in the west of Ireland. Even in the neighbourhood of London certain kinds bear moderate winters without shelter, especially *E. pulverulenta*. It is very much to be regretted that some settled nomenclature is not introduced, for the colonists apply the same names to different species in different parts of the country; this renders it difficult to tell of what they are speaking. As far as we can collect the evidence, it appears that the following are, or should be the botanical species to which the colonial names belong:—

Blue Gum of Port Jackson ...	*E. piperita.*
Blue Gum of Hobart Town ...	*E. globulus.*
Stringy Bark	*E. robusta.*
Iron-Bark	*E. resinifera.*
Kino-Gum	*E. resinifera.*
Peppermint Tree	*E. piperita*
Weeping Gum of Van Diemen's Land.	Uncertain.
Mountain Blue Gum of Van Diemen's Land	Uncertain.
Black Gum of Van Diemen's Land	Uncertain.
Black-Budded Gum of Van Diemen's Land	Uncertain.
Cider-Tree of Van Diemen's Land	Uncertain.
Manna Gum	Uncertain.
Manna of Moreton Bay	*E. Manna Cun.*
Blood wood of Port Jackson ..	*E. Corymbosa,*
WhiteGum ofVanDieman'sLand	*E. resinifera.*
White Gum of Moreton Bay...	*E. subulata-Cun.*
WhiteGum of the S.W Interior	*E. lencadendron Cun.—Eng. Cyc.*

Dr. Bennett, in his "Wanderings in New South Wales," states that a large quantity of camphorated oil, which closely resembles the cajeputi, is produced from the foliage of several species of *Eucalyptus*. Some of the leaves, which are of a bluish green, contain it in such abundance as to cover the hand with oil when one of the leaves is gently rubbed against it.—*Simmonds*. One of the species of Eucalyptus is called by the Australians Box tree and its bark, stringy bark, its

fibres are employed in making canvas and cordage, by the aborigines, as mentioned by Bennett —*Royle, page* 301. These trees might be useful in India.

(3494) EUCALYPTUS GUNNII, when wounded, furnishes the inhabitants of Van Diemen's Land with a copious supply of a cool, refreshing, slightly aperient liquid, which ferments and acquires the properties of beer.—*Eng. Cyc.*

(3495) EUCALYPTUS MANNIFERA, exudes a saccharine mucous substance resembling manna in its action and appearance, but less nauseous. It is not produced by insects, and only appears in the dry season. Other species yield a similar secretion at Moreton Bay and in Van Diemen's Land. Mr. Backhouse says it coagulates, and drops from the leaves in particles often as large as an almond.—*Eng*: *Cyc.*

(3496) EUCALYPTUS RESINIFERA.—*Syn.* E. Kino. Metrosideros gummifera. Botany bay *kino tree*, or brown gum tree. A native of Australia, cultivated in the Calcutta Garden. *E. resinifera* has leaves with very minute and numerous little dots, ovate lanceolate, with long tapering points narrowed to the base, with a vein next the margin. The flowers are umbellate, on a compressed peduncle rather longer than the petiole. The lid is conical, taper, leathery, twice as long as the capsule. The bark is so extremely astringent as to yield a gum not inferior to Kino, and sold as such. The bark of this and other species is so hard as to cause them to be called Iron-Bark Trees by the colonists. The Blue Gum-Tree and some others have the singular property of throwing it off in white or gray longitudinal strips or ribands, which, hanging down from the branches, have a singular effect in the woods. In many species the leaves are so variable in their form and other characters at different ages of the tree, or in different situations, that it is a matter of difficulty to know how they are to be botanically distinguished from each other; and in fact the subject of the distinction of species has hardly yet been taken up, no botanist feeling competent to undertake the task without some personal acquaintance with the plants in a native state. The leaves, instead of presenting one of their surfaces to the sky and the other to the earth, as is the case with the trees of Europe, are often arranged with their faces vertical, so that each side is equally exposed to the light. An astringent juice flows from this tree, named Botany Bay *kino*. Ainslie quotes *Dum-dul-ook-wain* as the Bazar name of this kino, but the term properly applies to the "Dragon's blood." It is infusible, occurs in fragments of variable size and form, often covered with brownish powder, brittle, thin, translucent and ruby coloured, fracture glassy and chocolate coloured, of variable depths of tint, destitute of odour. Taste

austere and somewhat bitter, powder red-brown; water dissolves about two-thirds, alcohol three-fourths, ether one-twentieth only. But there are different statements made by writers on this subject. Mr. White, who has witnessed the collection in Australia, says a single tree will yield 500 lbs. of this kino in one year by incisions practised on the bark. The medical uses of this article correspond exactly with those of *kino*, as already described. The bark and leaves are aromatic, but their essential oil has not been separated.—*O'Shaughnessy, page* 336. Its bark is a powerful tanning substance, and a single tree will often yield 60 gallons of an astringent resinous like substance from incisions in its bark; sold in the bazars of India as a kind of kino.—*Simmonds.*

(3497) EUCALYPTUS ROBUSTA, contains large cavities in its stem between the annual concentric circles of wood, filled with a most beautiful red or rich vermilion-coloured gum, which flows out as soon as the saw affords an opening.—*Eng. Cyc.*

(3498) EUCHARIDIUM. ONAGRACEÆ.—This is a small plant bearing a purple flower, and will thrive in a good garden soil.—*Riddell.*

(3499) EUGENIA, a genus of Dicotyledonous Polypetalous Plants of the natural order *Myrtaceae*, so named in honour of Prince Eugene of Savoy, who was a patron of botany and horticulture. The genus, as at present constituted, contains nearly 200 species, though numbers have been removed to the genera *Nelitris, Jossinia, Myrcia, Sizygium, Caryophyllus*, and *Jambosa*, in which are now contained the Clove-Tree, the Rose-Apple, and Jamoon of India, formerly included in *Eugenia*. This genus is confined to the hot and tropical parts of the world, as Brazil, the West India Islands, and Sierra Leone, and extends from the Moluccas and Ceylon to Silhet and the foot of the Himalayas in Asia. *Eugenia* is characterised by having the tube of the calyx of a roundish form, and the limb divided into four parts; the petals equal in number, and inserted on the calyx. The stamens are numerous. The ovary 2-3-celled, with several ovules in each. Seeds 1 or 2 roundish, and large, with the cotyledous and radicle united into one mass. In habit and inflorescence the species resemble many myrtles. Like the family to which they belong, some of the species of *Eugenia* secrete a warm volatile oil in their herbaceous parts; abound in tannin; yield good wood: and a few have fruit which is edible, though not very agreeable, from being impregnated with the aroma of the oil.—*Eng. Cyc.* Dr. Wight gives, in Icones,

(3500) EUGENIA. JAMBO FRUIT. A small black plum is often seen in Burmese bazars which is produced by a species of eugenia. According to Burman geography there is a eugenia tree on the great island or continent which we inhabit, that is twelve hundred miles high, one hundred and eighty-six in circumference, with five principal branches each six hundred miles long. From this tree, the island derives its name *Sambu-deba*, Eugenia Island.

(3501) EUGENIA ACRIS.

Sung, HIND.

A small tree; grows in Bombay, the leaves have a pleasant smell when bruised.—*Riddell.*

(3502) EUGENIA CARYOPHILIFOLIA. *Myrtaceae*, Icon. 553.

Nawel wood, ENG.	Naradidi Virksha, CAN.
Naredoo kurra, TEL.	Chota jamb, BENG.
Nawel marum, TAM.	Nareda Chettoo, TEL.

This is Ainslie's Calyptranthes Caryophyllifolia and his favorable account of the timber is such, as its appearance would lead one to expect. —*Wight.* It is a native of various parts of India growing luxuriantly in almost every soil and situation. Flowering time the hot season; bears a round berry, black when ripe, the size of a pea. The wood is whitish very strong, close grained hard and durable.—*Rohde, M.S.S.*

(3503) EUGENIA CARYOPHYLLATA.—*Syn.* CARYOPHYLLUS AROMATICUS. The cloves of commerce are the unopened flowers, the flower buds of the Clove-tree, *Caryophyllus aromaticus* (*Eugenia caryophpllata*), which was originally a native of the Moluccas, but is now cultivated in several parts of the East and West Indies. The tree may be propagated either from layers or seed. Layers will root in five or six months if kept moist. A strong dark loam, a gravelly,

sand, or clayey soil, but one not retentive of moisture, seems that best suited for its successful culture. It does not thrive well near the sea, nor in the higher mountains, the spray of the sea and the cold being found injurious. The plants at first require the shade of other trees, such as the mango, cocoa-nut, &c. Although generally a hardy plant, it suffers from excessive drought. They should be planted about twenty feet apart. In its native country the tree begins to yield fruit in the sixth year, but a crop can seldom be looked for in other quarters under eight years. It is very long lived, sometimes attaining the age of 130 years. There appears, according to Mr. Crawfurd, to be five varieties of the clove, viz—the ordinary cultivated clove; a kind called the female clove by the natives, which has a pale stem; the kiri or loory clove; the royal clove, which is very scarce, and the wild clove. The three first are equally valuable as species, the female clove being considered fittest for the distillation of essential oil. The wild clove, having scarcely any aromatic flavor, is valueless. The produce which may be expected from the tree seems to be uncertain; it may, however, be averaged at five or six pounds. A clove tree, well weeded and taken care of, will produce from five to twenty pounds. On the other hand, a tree that is neglected will not give above two or three pounds. At intervals of from three to six years they usually produce one extraordinary crop, but then a year now and then intervenes, when they yield none at all; in other they will afford a double harvest. The clove tree was originally confined to the five principal Molucca islands, and chiefly to Machean. From these it was conveyed to Amboyna, a very short time only before the arrival of the Portuguese. By them the cultivation was strictly restricted to Amboyna, every effort being made to extirpate the plant elsewhere. It has now, however, spread to Java, Singapore, and the Straits' Settlements, Ceylon, the Mauritius and Seychelles, Bourbon, Zanzibar, Cayenne, Dominica, Martinique, St. Kitts, St. Vincent, and Trinidad. The clove is remarkable for its limited geographical distribution. It is only in its native localities, the five small islets on the western coast of the large island of Gilolo, that it is easily grown, and attains the highest perfection. There, it bears in its seventh or eighth year, and lives to the age of 130 or 150. Rumphius informs us, that shortly before the arrival of the Portuguese it had been carried to and reared in Amboyna, where, however, it does not bear until its fifteenth year, and where the average duration of its life does not exceed 75 years. He informs us further that large islands are not favourable to its growth—that it succeeds indifferently even in such islands as Gilolo and Ceram, and that the natives of Celebes and Java who had attempted to grow it in their own countries had obtained plants which bore no fruit. Europeans, however, have succeeded somewhat better. The clove has been long transferred by them from the Moluccas to Sumatra,—to the islands in the Straits of Malacca,—to Bourbon,—to Zanzibar, on the eastern coast of Africa, and to Cayenne. In some of these places the culture has virtually failed, even where that of the nutmeg has succeeded, and everywhere the produce is of inferior quality to that even of Amboyna. A suitable soil seems to be as indispensable, as a suitable climate. The soil of the Molucca Islands is volcanic, which is not the case with any of the countries to which the tree has been transferred, except the Island of Bourbon, and here the suitable climate seems to be wanting. The clove appears, from Pigafetta's statement, to have been private property, and entirely free in culture and trade; Malays, Javanese, Chinese, Macassars, and Arabs, all competing for it in an open market. The annual quantity produced, according to him, in the five islands, seems to have been from 1500 to 2000 bahars; and the bahar is an Arabian weight, computed in the Moluccas at about 590 pounds. The companions of Magellan themselves loaded two ships with cloves at a single island, Tidor, after a stay, from their arrival to their departure, of no more than forty-four days. The Portuguese made their first appearance in the parent country of cloves in the year 1512: and having been expelled by the Dutch in 1605, they had the principal share of the clove trade for ninety-three years,—a period of rapine, violence, and bigotry. Their main object was the exclusive monopoly of spices, by the expulsion of all rivals. Their successors pursued the same object in a manner still more rigorous. They extirpated the clove trees in their native islands, and endeavoured to limit their growth to the five Amboyna islands, in which the clove is an exotic. Periodical expeditions for the extirpation of young plants that might spontaneously have sprung up, or been propagated by birds, formed part of this system. The clove monopoly still exists, but in a very tottering condition. The periodical exterminating expeditions have been merely nominal during the present century; and for the last thirty years, although the monopoly be persevered in, in the five Amboyna islands, where the parks, as they are called, are the property of the government, the culture and trade are legitimate everywhere else.—*Crawfurd Dictionary page* 104. The clove tree may be seen in a few gardens on the Tenasserim Coast, and cloves are abundant in the bazars. At the Madras Exhibition of 1855, *Cloves* were forwarded from Travancore, Tinnevelly, Canara, and Cochin. The plumpest and heaviest were from General Cullen's Gardens near Oodagherry, 1800 feet above the sea, these had a strong aromatic odour, and were of a dark brown colour; they were quite entire, and when pressed with the nail, the oil exuded.

The specimens from S. Warrier, Dewan of Cochin, and those from Tinnevelly District were almost equally good.—*M. E. J. R.* "The clove of Batavia is very dry, of a grey colour and appears to have been covered with plaster or lime (perhaps with talc). The clove of St. Lucea is of a whitish-yellow colour, and resembles the Cayenne clove with which it is frequently mixed. Cloves contain according to the analyses of Trommsdorf, volatile oil, 18: almost tasteless resin, 6; tannin, 13; difficulty-soluble extractive with tannin, 4; gum, 13; woody fibre, 28; and water, 18. The volatile oil is obtained from cloves by repeated distillation. The yield on an average is said to be from seventeen to twenty-two per cent. Cloves contain scarcely any starch. The quality and value of cloves are not unfrequently impaired like some other spices, by the abstraction of the essential oil. Cloves which have been thus deprived of their active properties, are distinguished by being light, shrivelled, not yielding oil when pressed upon, possessing but little aroma or taste, and by the frequent absence of the flower-bud. This fraud used to be extensively practised in Holland, the drawn cloves for more effectual concealment being mixed with others of good quality and even in some instances the trouble being taken to restore as nearly as possible to the exhausted cloves their original appearance by rubbing them over with some common oil. The volatile oil itself as imported into Britain from India has been found to be adulterated. Mr. McCulloch on the authority of Milburn states that the oil imported from India contains nearly half its weight of an insipid expressed oil which is discovered by dropping a little into spirits of wine and on shaking it the genuine oil mixes with the spirit and the insipid separating the fraud is detected. Cloves readily imbibe moisture whereby their weight becomes greatly increased; a fact of which dishonest dealers have not failed to avail themselves. Cloves are but seldom sold in powder, and hence the liability to adulteration is greatly lessened; they are however occasionally met with in that state. Clove-stalks although very inferior, contain some of the active properties of cloves and as already noticed are occasionally used by distillers for procuring the essential oil of cloves. We have reason to believe that in some cases the stalks are ground up and mixed with the powder of genuine cloves; this sophistication can be readily detected in a most satisfactory manner. The cloves-stalks present a structure somewhat similar to that of cloves themselves: that is they consist of cellular tissue hollowed out here and there into receptacles for the essential oil but in addition the stalks are provided with an epidermis or coating of the stellate cells which are of such frequent occurrence in different kinds of bark.—*Wood and its adulterations, page* 414.

(3504) EUGENIA JAMBOLANA.

Rose apple wood, ENG. | Burra jamoo and Race jamoo, HIND.
Pedda neroodoo and Sanna neroodoo, TEL. | Peroo naga Sinee naga, and Keatty naga marum, TAM.

This wood is said to be brittle and bad, but is described by Ainslie as fit for house building purposes.—*Wight.* In Burmah the bark is used as a mordant for blue and black dyes.—*Mason.* It grows to be a very large tree common everywhere both wild and cultivated, every soil and situation suiting it equally well, flowering time the beginning of the hot season, seed ripens in July and August. The wood is hard, close grained and durable. The bark is strongly astringent, and dyes excellent durable browns of various shades according to strength of decoction. The fruit is eaten when ripe by man and birds. They have a subacid astringent taste. There is a variety of the fruit in the Northern and mountainous parts of the Eastern Coast of superior quality and as large as a pigeon's egg.—*Rohde M.S.S.*

(3505) EUGENIA JAMBOS. Lin.

Jumboonawel pullum, TAM. | Jambo, CYNG.
Ghoolabijam, DUK. | Goolab-jamun, PERS.
Jembooneredei pundoo, TEL | Rose Apple, ENG.
Jamb, HIND. and MAL. | Raja Jemboo, SANS.

This tree bears a light whitish yellow fruit, pear shaped, with smooth skin, having a rose flavor: it is commonly cultivated in gardens on the coast. Hyderabad is the only part of the Deccan where it is known to flourish; many attempts have been made without success to rear it elsewhere. It is easily propagated by seed, and grows luxuriantly in a good garden soil. The red coloured species having the same flavor, is called the Jambo Malacca. E. Jambos, Syn. Jambosa vulgaris. The fruit of Eugenia Jambos is not much esteemed, and has got its English name from smelling like a rose.—*Ainslie, p.* 228. In Tenasserim, the rose apple described as "tasting like the smell of a rose," is cultivated to a small extent in European gardens.—*Mason.*

(3506) EUGENIA MALACCENSIS. Linn. JAMBOSA MALACCA.

Jamboo Malaca pullum, TAM. | Namball paio, MAL.

The tree which bears this fruit was first brought to India from Malacca. It is of the class Icosandria and order Monogynia. The produce somewhat resembles a pear in shape, is pleasant to the taste, and is reckoned very wholesome.—*Ainslie, page* 225. This tree thrives luxuriantly at Mergui, and bears some resemblance in taste to a juicy apple, but it is a very indifferent fruit.—*Mason.*

(3507) EUGENIA MICHELII is a Brazilian species, cultivated in Martinique where it is called Cerisier de Cayenne, as it yields a small edible fruit.—*Eng. Cyc.*

(3508) EUGENIA PIMENTA, the Allspice

Pimento, or Bayberry-Tree, is a native of South America and the West India Islands, especially Jamaica, and from being cultivated there is often called Jamaica Pepper. The tree is very handsome, often 30 feet high, and much resembles the Clove-Tree in the form and appearance of its leaves, as well as in habit. The trunk is smooth, and much branched towards the top. The older branches are round, the younger compressed, and the twigs as well as the flower-stalks pubescent; the leaves are petiolate, oblong or oval, smooth, and marked with pellucid dots, forming a dense evergreen foliage; the flower-stalks are both axillary and terminal, and are divided into 3-forked panicles; the flowers are small, without show, and conformable in structure to the character of the genus. The berry is spherical and crowned with the persistent calyx; when ripe, smooth, shining, and of a dark purple colour; usually 1-celled, occasionally 2-celled, containing large roundish seeds. The *Pimenta* is cultivated with great care in Jamaica, and abounds especially on the hills on the north side of the island. The trees are formed into regular walks, and begin to bear when three years old, but are not in perfection until they have been planted seven years. They thrive best in rocky lands, or a rich soil having a gravelly bottom. Mr. Bryan Edwards says that a single tree has been known to yield 150lbs. of the raw fruit, or 100lbs. of the dried spice; but the crop is uncertain, and plenteous perhaps only once in five years. The tree has been introduced into and flourishes in the southern parts of India. The berries, being the valuable part of the tree, require care in gathering as well as drying; the processes for which are described by Browne in his 'History of Jamaica,' page 248. They must be picked when they have arrived at full growth, but before they begin to ripen; they are dried in the sun, on raised boarded floors, and frequently turned during the first and second day; they are then put into sheets, often winnowed, and exposed to the sun until sufficiently dried, which is known by the colour and the rattling of the seeds in the berries. Browne says, "Such of the berries as come to full maturity do, like many other seeds, lose that aromatic warmth for which they are esteemed, and acquire a taste perfectly like that of Juniper Berries, which renders them a very agreeable food for the birds, the most industrious planters of these trees." The leaves and bark participate in the warm aromatic properties for which the berries are celebrated, and which have received their name of Allspice from their fragrant odour being thought to resemble that of a mixture of cinnamon, cloves, and nutmeg. Their taste being warm and aromatic makes them useful as a spice in cookery, and a stimulant in medicine.—*Eng. Cyc.* See ALLSPICE.

(3509) EUGENIA PULCHELLA. 1 Khwaytha-byai. Very plentiful in the Pegu and Toungh00 districts. 2. *E. myrtifolia*, 2 Thabaijeen. 3. *vulgaris*, 3 Thabyaitha-phan. 4. *ternifolia* and *jambolana*, 4 Thabyewtha-byai. Burm. also occur, but less plentifully than the first-mentioned species. They all afford excellent close-grained strong timber, but subject to the attack of white ants. Wood, red-colored, strong and adapted for house-building.—*McClelland.*

(3510) EULOPHIA (from εὖ, and λόφος, a crest), a genus of Plants belonging to the natural order *Orchidaceæ*. It has an open spreading perianth; the sepals and petals ascending, nearly equal, either quite distinct, or united with the more or less lengthened base of the column; the lip corned or shortly spurred, sessile, with the veins crested, bearded, or quite smooth, usually 3-lobed, sometimes undivided; the column half-terete, edged; the anther terminal, opercular; the pollen masses 2, waxy, 2-lobed, or hollowed out at the back, with a short linear caudicula, and a transverse gland. The species are terrestrial plants, with pseudo-bulbous rhizomata, long membranous plaited leaves, and radical many-flowered scapes. Most of the rhizomata and roots of the species of the family *Orchidaceæ* yield starch in a peculiar form. The roots of the species of *Orchis* are used in Europe under the name of Salep as an article of diet, and the same use is made of the rhizomata of a species of *Eulophia* in the East Indies. Although specimens of the plant were brought from Cashmere by Dr. Royle, they were not in a state of preservation to be identified. (Lindley, *Flora Medica.*)—*Eng. Cyc.*

(3511) EUONYMUS TINGENS. The bark in the inside is of a fine yellow colour similar to that of Rhamnus. It is used to mark the *Tika* on the forehead of the Hindus, and is considered by the natives to be useful in diseases of the eye (*Royle.*)—*O'Shaughnessy, page* 272.

(3512) EUPATORIUM, a genus of Plants belonging to the natural order *Compositæ*, the tribe *Eupatoriaceæ*, the sub-tribe *Eupatoriæ*, and the division *Adnostyle*. It has 3-100-flowered heads, a flat naked receptacle, the scales of the involucre in one or two or more rows, equal or unequal, loosely or closely imbricated, the throat of the corolla hardly dilated, the anthers inclosed, the arms of the style exerted, cylindrical, obtuse; the pappus in one row, hairy, rough.—*Eng. Cyc.*

(3513) EUPATORIUM AYAPANA.

Aya-pana, BEN.

Has subsessile, opposite, lanceolate, triple-nerved, acuminate, nearly entire, smooth leaves. It is originally a native of South America, on the right bank of the river Amazonas, whence it has been introduced into the East Indies. It has a stem shrubby at the base, branched, and smooth; the heads are pedicellate, and contain about 20 flo-

rets. An infusion of this plant is used in Brazil as a diuretic and diaphoretic. It has also been employed as an antidote against the bites of venomous serpents and insects. A quantity of the bruised leaves is laid upon the scarified wound, and the fresh juice is administered from time to time to the patient. The reputation of this plant for the bites of poisonous serpents, like that of many others, is probably undeserved. Other species of *Eupatorium* possess medicinal properties: *E. aromaticum* and *E. odoratum* have very fragrant roots; *E. perfoliatum* and *E. rotundifolium* have been employed in renal diseases and consumption. The *E. Guaco* of older botanists is now referred to the genus *Mikania*. (Burnett, *Outlines of Botany*; Lindley, *Flora Medica*; Lewis, *History of Materia Medica*.—*Eng. Cyc.* Odour slightly aromatic, agreeable, and balmy. Taste aromatic, astringent, and bitter. By Cadet de Gassicourt's analysis the stems and dried leaves appear to yield brown aromatic extract, volatile oil, gallic and benzoic acids. The infusion is very agreeable, resembling that of the coarser varieties of tea. The plant has had immense celebrity, and has been used in fever, cholera, tetanus, snake bites, and other most dangerous cases. All the romance about its extraordinary virtues are now however exploded; and we know it only as an agreeable and useful diaphoretic and gentle tonic.—*O'Shaughnessy*, *p.* 422.

(3514) EUPATORIUM PERFOLIATUM, or *bone-set*, is possessed of greater bitterness and less aroma, than E. Ayapana, and is stated to be employed with much success as an antiperiodic in the intermittent fevers of the United States of America.—*O'Shaughnessy*, *p.* 422-23.

(3515) EUPHORBIA, a genus of Exogenous Plants, giving its name to an extensive and important natural order. It has very small monandrous naked male flowers, crowded round an equally naked female one, in the inside of an involucre looking like a calyx, and formerly mistaken for that organ. The species have either a common leafy appearance, with the involucres proceeding from among large foliaceous bracts, or they are nearly leafless, with their stem excessively succulent, so as to resemble *Cacti*. Those with the former character are natives of most parts of the world, and are the only kinds found in Europe; succulent species chiefly appear in the hottest and driest countries. Barren uncultivated places in the plains of Hindustan, and the arid regions of Asia and the north of Africa are their favourite stations; in the Canaries, on volcanic soil, *E. Canariensis* and *E. laphylla* form great bushes with arms like candelabras. From *Cacti*, which some of these plants much resemble, they are readily known by their spines, when they have any, not growing in clusters, and by their emitting, when punctured, an abundant discharge of milky juice. This, in a concrete state, forms what is called the gum-resin, or rather resin, called *Euphorbium*, an acrid, corrosive most dangerous drug, principally furnished by *E. officinarum*, *E. antiquorum*, and *E. Canariensis*. The same properties exist in the herbaceous leafy species, diffused in some, concentrated in others. —*Eng. Cyc.* *E. peplus*, is purgative and emetic, in dose of 24 gr. *E. gerardiana*, *E. pithyusa*, *E xyloatica*, same effect, dose 15 to 24 gr.—*O'Shaughnessy*, *p.* 565.

(3516) EUPHORBIA AGRIA, (affinis species) grows in the mountains of Cashmere, where it is officinal. The root of this plant is sometimes as thick as an arm, knotty, with boughs, and is blackish, whence the Cashmerians call it the black Hirbee (Euphorbia) and consider it the strongest of all other species (white, yellow, etc.) A man who had taken such a root out of the ground not having observed the rule to have the wind, behind him, got a swollen face, from the powerful vapors.—*Honigberger*, *page* 274.

(3517) EUPHORBIA ANTIQUORUM. True Euphorbia.

Thuar, Hind.

E. antiquorum is common on barren and uncultivated lands all over India and Arabia Felix. It has a shrubby leafless succulent stem. The branches are spreading, triangular or quadrangular, the angles sinuated, and armed with double spines at the protuberances. The peduncles are solitary or in pairs, 3-flowered. There are only 5 stamens. The bark of the root when bruised in water is taken as a purgative. Some writers consider that this plant yields the drug *Euphorbium*, a resinous substance possessing acrid irritant properties. In all probability however this substance is chiefly obtained from *E. officinarum*. The Arabs make up violent diuretic pills by rubbing over the juice of *E. antiquorum* with flour, yet their camels will eat the branches when cooked. The juice of *E. heptagona*, *E. virosa*, and *E. cereiformis*, African species, furnishes the Ethiopians, and *E. continifolia*, the wild Brazilian, with a mortal poison for their arrows. The juice of the leaves of *E. nereifolia* is prescribed by the native practitioners of India internally as a purge and deobstruent, and externally, mixed with Margosa oil, in such cases of contracted limb as are induced by rheumatic affections. The leaves have no doubt a diuretic quality. Of the leafy Euphorbias great numbers are found to possess a milk with purgative or emetic qualities. The roots of some of the species are emetic. According to Deslongchamps the powdered root of *E. Gerardiana* is emetic in doses of 18 or 20 grains. The root of *E. Ipecacuanha* is said by Barton to be equal to the true Ipecacuanha—in some respects superior. *E. Pithyusa* is esteemed in the Mediterranean. *E. thymifolia* is somewhat aromatic and astrin-

gent, and is prescribed in India in the diarrhœa of children, and as a vermifuge. In the same way is employed *E. hypericifolia*, a plant of tropical America, which is astringent and somewhat narcotic. Nevertheless, *E. balsamifera* has no such qualities, and is eaten when cooked, *E. Mauritanica* is also employed as a condiment; but its acridity is unpleasant. It is said to be used in adulterating scammony. The sap of *E. phosphorea* shines with a phosphorescent light in a warm night in the ancient forests of Brazil. (Lindley, *Vegetable Kingdom.*)—*Eng. Cyc.* According to Dr. O'Shaughnessy, no Euphorbium resin is obtained from this species in India.—*O'Shaughnessy, page* 564. It occurs abundantly and other writers say that an immense quantity of gum resin, might be collected from it. The dried stalks are the cheapest of firewoods.—*Irvine.*

(3518) EUPHORBIA BOJERII. BOJER'S EUPHORBIA. This large scarlet-flowered species of euphorbia from Madagascar is very common in gardens in Tenasserim.—*Mason.*

(3519) EUPHORBIA CASHMEREANA TSOK, Tsuk—this root is of a dark brown colour, about an inch thick and is officinal in Cashmere.—*Honigberger. p.* 274

(3520) EUPHORBIA CYPARISSIAS. Syn. Tithymalus Cyparissias. Τιφυμαλος. Diosc. iv. 165. Europe. Root excessively acrid. Des Longchamps considers the bark of the root a good emetic in doses of 12 to 18 grains. —*O'Shaughnessy.*

(3521) EUPHORBIA CUTTIMUNDOO. This species and its product was discovered in the Northern Circars, and brought to public notice by Mr. Walter Elliot. See CUTTIMUNDOO.

(3522) EUPHORBIA EPITHYMOIDES, v. Euphorbia verrucosa.—*Honigberger, p.* 274.

(3523) EUPHORBIA HELIOSCOPIA, vegetates in the gardens of Cashmere. The juice is very acrid and irritating. The seeds of this plant are officinal, and combined with toasted pepper are recommended in Cholera.—*Honigberger, p.* 274.

(3524) EUPHORBIA IPECACHUANA. Action of root exactly like that of Ipecachuana, but more violent. It only requires to be given in proportionally small doses to be a perfect substitute for the best ipecachuan.—*O'Shaughnessy, page* 565.

(3525) EUPHORBIA LATHYRIS, Spurge. A common weed in cottage gardens, where it is called Caper, yields from its seeds an oil of the most violent purgative nature. If it were less dangerous it might be substituted for Tiglium oil. Fee states that with as much of this oil as could be sold for a franc ninety adults might be purged.—*Eng. Cyc.* The seed of this Euphorbium contains yellow fixed oil, stearine, acrid brown oil, crystalline matter, brown resin, an extractive colouring matter, and vegetable albumen. —*O'Shaughnessy, page* 565.

(3526) EUPHORBIA LIGULARIA, Bengal, Roxb. ii. p. 465.

Munsa sij, BENG.

A plant sacred to Munsa, the goddess of Serpents. The root of the tree mixed with black pepper is employed for the cure of snake bites, both internally and externally.—*O'Shaughnessy, page* 564.

(3527) EUPHORBIA LIGULATA. This large columnar *Euphorbia* is common all along the Soane, and is used everywhere for fencing. The *E. Neriifolia*; and the *E. Tirucalli* had been very rarely seen since leaving Calcutta.—*Hooker, Him. Jour. Vol.* 1. *page* 46

(3528) EUPHORBIA LITCHI. This fruit tree, introduced into India from China, attains a height of 25 to 30 feet but does not ripen its fruit at Madras.—*Hort. Gard.* 18.

(3529) EUPHORBIA LONGIFOLIA, its yellow root is long and smooth from about half an inch to an inch in diameter and is called the yellow Hirbee. This species is used at Lahore as well as in Cashmere. The Cashmerean Surgeons apply it in fistulous sores, etc.—*Honigberger, page* 275.

(3530) EUPHORBIA NERIIFOLIA, OLEANDER LEAVED EUPHORBIA. Roxb. ii. p. 467. E. Nivulia, Hamilton.

Patteoon, DUK.	Ela-Kullie, TAM.
Pattakarie, SANS.	Sij, HIND.

Branches round, otherwise like last species, juice used by the natives as a purgative, externally as a stimulant in rheumatism and contracted limbs; leaves diuretic.—*O'Shaughnessy, page* 565. Grows all over the rocky parts of the Deccan. It has a whitish dead appearance except during the rains, and forms a capital fence round fields, &c.—*Riddell.* Abundant over all the Hills within some miles of Ajmeer.—*Irvine.*

(3531) EUPHORBIA OFFICINARUM. Arabia, and Africa. Mr. Pereira considers the Mogadore Euphorbium resin to be produced by this species, which has a bright crimson flour.—*O'Shaughnessy, page* 564.

(3532) EUPHORBIA PILULIFERA. UMAWM PATCHEH-ARISE, T.—An abundant weed to be found every where; used but seldom, mixed with others as greens.

(3533) EUPHORBIA THYMIFOLIA. All over India. Thyme-leaved Euphorbia.

Shwet keerooi, BENG.	Dudhi, HIND.
Racta vinda chada, SANS.	

A little annual plant, flowers white and red,

juice of stalks and flowers a violent purgative, fresh plant applied to wounds by the Arabs, leaves and seeds given by the Tamools in worm cases, and in the bowel affections of children.—*O'Shaughnessy, p.* 565. Euphorbia thymifolia vegetates at Lahore, but is seldom used. The natives call this plant the greater milky one, on account of its erect stalks and milky juice. The former creep along the ground. The juice of the stalk and flowers is said to possess violent purgative qualities. The leaves I used both of this and of the abovementioned, were not very acrid. A very common weed every where in the plains.—*Dr. Honigberger, page* 275.

(3534) EUPHORBIA TIRUCALLI. Milk hedge, *Roxb. Fl. Ind.* ii. *page* 370.

Lunka sij, BENG.	Sendh, HIN.
Milk-hedge, ENG.	Kulli, TAM.—*O'Shaugh.*

Euphorbia Tirucalli has erect naked round branches, which are succulent, polished, and abounding in milky juice. The leaves are small, linear, fleshy, sessile, and at the ends of the twigs. The flowers are crowded, sub-sessile, terminal, and axillary; the lobes of the involucre are five in number, roundish, smooth, and peltate; the tube woolly on the inside. The capsule is villous. The milk when introduced into the eye produces severe inflammation and even blindness. It is used medicinally in India.—*Eng. Cyc.* This plant is much used for making hedges, and from its continual green appearance is well adapted for the purpose. It grows best either upon a bank, or wall of large stones laid loosely for the purpose, having a good cover of earth upon it. Any cuttings will grow, and the plant if by itself will attain the height of twenty feet or more. The wood makes the best charcoal for gunpowder. A parasite of a yellow thread-like appearance, and leafless, (the Cassytha filiformis) is very destructive to it, and will totally destroy a tree or a whole hedge in a short time, if not removed.—*Riddell.* Wood light colored, the root of old shrubs is understood to be well adapted for gun stocks, but plants of sufficient age are seldom met with.—*Madras Exhibition of* 1855. The milk mixed with flour, in doses of a drachm daily is, an Indian specific in syphilis. The inspissated milk is a violent emetic and purgative.—*O'Shaughnessy, page* 563.

(3535) EUPHORBIA TITHYMALOIDES. The Slipper Plant. This is thick deep-green leafed plant: it grows about three feet high, but if kept trimmed may be used for a border to a flower parterre, for which purpose it is admirably adapted. It suffers nothing by cutting, and if occasionally watered is always green. It grows well from slips; bears a small pink flower, and can be kept at any height. It is sometimes called buckthorn.—*Riddell.*

(3536) EUPHORBIA TORTILIS. Rottl. Tirooghoocullie.

Tirooghoocully, TAM.	Jemoodoo, TEL.
Peelie sayad DUK.	Vajratoonda, SANS.
Azfur sukkoom, ARAB.	

The milky juice of this plant, which has got its Tamul name from its branches being as it were scolloped and twisted, is very similar in its appearance and nature to that of the Euphorbia antiquorum, and is a very powerful cathartic and deobstruent: it is prescribed in small doses in conjunction with Palmira jaggery. In its undulated state it acts as a vesicatory but when mixed with a certain portion of castor oil it forms a useful embrocation in cases of Palsy and chronic Rheumatism. The flowers of this jungle plant Dr. Ainslie had never seen. The plant itself would appear to differ from the Euphorbia antiquorum chiefly in the shape of its branches which in place of being three sided and distinct, are contorted, undulating and, as it were, scolloped, are of a yellow green colour, and contain much more milky juice.—*Ain's Mat. Med. p.* 120.

(3537) EUPHORBIA TRIBULOIDES, has a stem about two inches high and one inch broad, ovate, fleshy, quadrangular, having two opposite, stalked, ovate spathulate leaves growing from its base. The prickles are in pairs, white, clustered on the margin of the angles. It is said to be a sudorific.—*Eng. Cyc.*

(3538) EUPHORBIA VARIEGATA, will be raised from seed in any common garden soil.—*Riddell.*

(3539) EUPHORBIACEÆ, SPURGEWORTS, a natural order of Exogenous Plants with definite suspended anatropal ovules, scattered flowers, and tricoccous fruit. The genera consist of trees, shrubs, or herbaceous plants, often abounding in acrid milk. The leaves are mostly opposite or alternate, simple, rarely compound, often with stipules. The flowers are axillary or terminal, arranged in various ways, sometimes inclosed within an involucre resembling a calyx; flowers monœcious and dicœcious. The calyx inferior, with various glandular or scaly internal America, not above an eighth having been found in tropical Africa, including the islands; a sixth is about the proportion in India. A good many species inhabit the Cape, where, and in the north of Africa, they often assume a succulent habit; and there are about 120 species from Europe, including the basin of the Mediterranean, of which 16 are found in Great Britain, and 7 in Sweden. A large number of these plants are poisonous. The poisonous principle resides chiefly in their milky secretion. The hairs of some are stinging. The bark of many is aromatic; and the flowers of some tonic. Many are used in medicine, such as *Croton, Cascarilla*, and *Euphorbia*. The stimulating poisonous principle however appears to be volatile since the action

of heat is sufficient to dispel it. Thus the starchy root of the Manihot, or Cassava, which when raw is a violent poison, becomes a wholesome nutritious food when roasted. Some yield a fixed oil from their seeds, as the species of *Elaeococca*. For further particulars respecting the important and various properties of the species of this order, see Pedilanthus, Croton, Buxus, Cascarilla, Jatropha, Ricinus, and Euphorbia. The order contains 191 genera, and 2800 species.—*Eng. Cyc.*

(3540) EUPHORBIUM.

Furfioon, Akal-nafzah, Gholak, kala, ARAB.	Sayud-ka dood, Nara shij. HIND.
Nara-shij, BENG.	Euphorbium, LAT.
Dalookgaleh-keery, CING.	Vajrakshira. Vajrakantaka. SANS.
Sayud-ka dood, DUK.	Shadraykullie pall, TAM.
Euphorbe. FR.	Bonta-jeemmoodoo paloo TEL.
Euphorbien gummi, GER.	

The produce of a perennial plant, a native of Africa, and of many parts of India, &c. It is a concrete gum-resin; is inodorous; when first chewed has little taste, but it soon gives an acrid burning impression to the tongue, palate, and throat, which is very permanent and almost insupportable. It is met with in small, hollow, forked pieces, often mixed with seed, and other impurities. *Thomson's Chemistry.—Faulkner.*

(3541) EUPHRASIA (from εὐφρασια, delight) a genus of Plants belonging to the natural order *Scrophulariaceae* or *Ecrophularineae*. It has a campanulate 4-cleft calyx; the upper lip of the corolla galeate, emarginate, the lower larger, spreading, with the middle lobe emarginate; 4 stamens, fertile, the lower cells of the upper anthers with a long spur; the capsules oblong-ovate, compressed, emarginate, with entire valves; the seeds few.—*Eng. Cyc.*

(3542) EUPHRASIA OFFICINALIS. Euphrasy. Eye-bright, has ovate or cordate-ovate nearly sessily serrate leaves, the corolla glabrous, the lobes of the lower lip emarginate, of the upper lip patent sinuate-dentate, the anthers unequally mucronate, hairy. It is from one to four inches high, and is a native of the heaths and pastures of Europe, the Himalaya mountains, Cashmere, and all the north of Asia. It is common in Great Britain. This species is particularly subject to variation. The leaves are ovate, or cordate-ovate, or cordate-triangular, with the teeth acute or obtuse, ascending or spreading. The capsule also varies much in shape. There is scarcely a character permanent except the pubescence of the corolla. This elegant little plant has a slightly bitter and aromatic flavour, and has been employed much in medicine, particularly in disease of the eye. Its use in these complaints seems to have originated in its bright appearance, and when the doctrine of signs and seals prevailed this was supposed to indicate its value in brightening the eyes. Although it has lately fallen into disuse its astringent effect is undoubtedly of value in certain diseases of the eye, and will explain the fact that Professor Kramichfeld has related of its being useful in catarrhal affections of the eye. The expressed juice and distilled water of this plant have been the forms in which it have been employed.—*Eng. Cyc.* Eye-bright is a pretty plant, slightly bitter and aromatic, once celebrated as an application to weak eyes, but now seldom or never employed.—*O'Shaughnessy, p.* 478.

(3543) EURYALE, (after one of the Gorgons, in allusion to the threatening armed appearance of the plant), a genus of Plants belonging to the natural order *Nymphoeaceae*. It has a calyx of 4 sepals inserted in the torus, and adhering to it; 16-28 petals; numerous stamens; 16-20 carpels; the fruit half-inferior, arising from the sepals; petals and stamens adhering half-way up. There is but one species of this genus, *E. ferox*, which is an elegant aquatic, covered all over with prickles, with large peltate orbicular leaves, and bluish-purple or violet flowers, about the size of those of the yellow water-lily. It is a native of the East Indies in the Gumtoe and Gogra, also in the province of Kianang in China. This plant presents a very singular appearance. Its petioles and calyces are hispid with stiff prickles. The leaves are about a foot in diameter. The root or root-stock contains starch, which may be separated as food, or the roof may be eaten, as is done by the inhabitants of the districts where it grows. In cultivation, this plant must be kept in water in a hotbed or stove. It will produce seeds if the pollen of the anthers, when it is in full bloom, be shaken on the stigmas. It can only be propagated by means of its seeds.—*Eng. Cyc.*

(3544) EURYALE FEROX. An Indian water-lily with a small red flower covered everywhere with prickles, and so closely allied to *Victoria regia* as to be scarcely generically distinguishable from it. It grows in the eastern Sunderbunds, and also in Kashmir. The discoverer of Victoria called the latter "*Euryale Amazonica.*" These interesting plants are growing side by side in the new Victoria house at Kew. The Chinese species has been erroneously considered different from the Indian one. The fruit of *Euryale ferox*, is round, soft, pulpy, and the size of a small orange; contains from eight to fifteen round black seeds as large as peas, which are full of flour, and are eaten roasted in India and China, in which latter country the plant is said to have been in cultivation for upwards of 3000 years.—*Hooker Himalayan Journ. Vol. ii. p.* 255.

(3545) EURYCLES AMBOINENSIS. A fragrant white flowering bulb of the amaryllis tribe, and of the genus eurycles, is not uncommon in native gardens of Tenasserim.—*Mason.*

(3551) EVOLVULUS EMARGINATUS.—Lin.

Yelichavy keeray, TAM. | Shamburdie, SANS.
Yellakachevie koora, TEL.

This is the green of a plant of the class Pentandria and order Tetragynia.—*Ainslie's Mat. Med. page* 258.

(3552) EXACUM. *Sibth. Prod.* N. 135 Tetrandria Monogynia. Dr. Wight gives the following species, Exacum bicolor, 1321; Courtallense, 1323; *hyssopifolium*, 600; pedunculare, 336; Perrottetii, 1322; petiolare, 1324; pumilum, 1324; sessile, 1324; Wightianum, 840; and Zeylanicum, 1322.

(3553) EXACUM BICOLOR, Nat. Ord. Gentianeæ, Country kreat, *Eng.* The plant grows in Cuttack, at Mangalore and on the Neilgherries and has long been used as a bitter tonic.—*Ind. Ar: No.* 6. It grows, rare, on the Neilgherries, below Kotagherry, and abundant a mile below Nedawattum, where it flowers during the autumnal months. This species enamels the swards of the Western Ghauts with its beautiful blossoms, has the same bitter stomachic principles for which the Gentiana lutea is so much employed, and it is believed may be used with advantage in lieu of Gentian, for medicinal purposes. It is known in Mangalore as country creat, and sold there at 1 anna 6 pie per lb. The infusion of *E. bicolor*, is a mild pure bitter.

(3554) EXACUM TETRAGONUM, Nat. Ord. Gentianæ Ooda Cheretta *Hind.* purple *Chiretta.* Koochuri *Bengalies.* A most elegant plant, used as a tonic bitter.

(3555) EXCÆCARIA, a genus of Plants belonging to the natural order *Euphorbiaceæ.* It has monœcious or dioecious amentaceous flowers; the sterile flowers nothing but staminiferous bracts; the stamens 7-9, united into about three parcels, all connected at the base; the fertile flowers with the calyx 3-fid or absent; the style 3-parted; the capsule 3-coccous.—*English Cyc.* Wight figures Exæcaria Agallocha, 1865; crenulata, 1865; and oppositifolia, 1865.

(3556) EXŒCARIA AGALLOCHA. Aloe wood? Arbor excæcans, *Rumph.* Amb. ii. t. 79, 80. East Indies.

Ugoorpo, Sundarbunds. | Bone hayaga, BURM.
Bing.

Wood knotty, grey or blackish, smooth, and resinous.—*O'Shaughnessy, page* 563. *E. Agallocha* is a small crooked stunted tree, with alternate leaves about the extremities of the branches, stalked, ovate, or cordate, but usually acute at the base, smooth on both sides, remotely and slightly serrate, pointed with two glands at the base, and about two inches long; the petioles about an inch long, smooth, channelled; the stipules small, fine-pointed. The trunk of this plant abounds in a virulently acrid milk, which acts as a powerful poison. Roxburgh says that wood-cutters who accidentally injure this tree have inflammations and ulcerations on those parts of the body where the milk touches. Rumphius calls this tree 'Arbor excæcans,' and says that the Dutch sailors, who were sent ashore at Amboyna to cut down timber, became furiously mad from the pain produced by the juice of this tree getting into their eyes, and that some of them lost their sight altogether. This tree is common in various parts of the continent of India, and in the Indian Islands, especially near the coast. Its specific name appears to have been given it on the supposition that it was one of the plants that yielded the *Agallochum*, or Aloes-wood, but this is not the case, and this wood is yielded by a different family of plants.—*Eng. Cyc.* This is plentiful in the Rangoon and Tounghoo districts. The wood is white colored, adapted to every purpose of house-building.—*McClelland.*

(3557) EXOCETUS, a genus of Fishes belonging to the Abdominal *Malacopterygii*, forming part of the family *Esocidoe.* The distinguishing characters are—pectoral fins nearly equal to the body in length; head flattened above and on the sides; the lower part of the body furnished with a longitudinal series of carinated scales on each side; dorsal fin placed above the anal; eyes large; jaws furnished with small pointed teeth.—*Eng. Cyc.*

(3558) EXILE TREE. Thevetia neriifolia.

F

(3559) [illegible] genus of Plants belonging to the natural order *Leguminosæ.* It has a tubular 5-cleft or 5-toothed calx, with the two superior teeth shortest. The style is villous at the apex. The legume is large and coriaceous, lined with short hairs, and containing several large flat seeds. The leaves are almost without tendrils, and the stem is erect. The flowers are white or [illegible].—*Eng. Cyc.*

(3560) FABA VULGARIS, the Common Bean, has thick leaves with 2-5 broad oval mucronate leaflets. It has semi-sagittate oval stipules, and the teeth of the calyx are almost linear. This plant is much cultivated, and subject to considerable variety. Its seeds differ [illegible] sometimes round and comparatively small, at other times large and flat. The flowers are mostly white, with a black or blue milky spot in the middle of the two lateral petals called wings. The Common Bean is said to be found wild in Persia, no

far from the Caspian Sea, but it is one of those plants, which, having from time immemorial been cultivated by man, may have anywhere been introduced by his agency. It does not occur wild in the countries of Europe, where it grows most luxuriously under the care of man.—*Eng. Cyc.*

(3561) FABACEÆ, *Leguminous Plants*, a name proposed by Dudley in his 'Vegetable Kingdom' for the natural order *Leguminosæ*.—*Eng. Cyc.*

(3562) FAGHURRA JABRONG a spice of Assam and Himalayas.

(3563) FAGOPYRUM, a genus of Plants belonging to the natural order *Polygonaceæ*. It has a 5-parted perianth, 8 stamens, 3 styles, a 1-seeded trigonous nut, a central embryo, and large foliaceous contorto-plicate cotyledons There is but one British species of this plant, the *F. esculentum*. This is the *Polygonum Fagopyrum* of Smith, and known as the common Buck-Wheat. It has an erect stem without prickles, the flowers in cymose panicles, 8 stamens, leaves cordate, sagittate, acute, a triquetrous acute nut, with entire angles. This is a valuable plant, as it grows on the worst and poorest soils, and is often sown as food for game. Though now admitted into the British Flora, there can be no doubt that it was originally a native of Persia and other Asiatic countries. It was introduced into Europe by the Crusaders; and hence in many parts of France, where it is commonly grown, is called Saracen Corn; and so much is it esteemed in Belgium, that M. Bory St-Vincent says he was shown the tomb of the person who is reported to have first brought it into that country. (Babington, *Manual of British Botany*; Burnett, *Outlines of Botany*.—*Eng. Cyc.*

(3564) FAGRÆA FRAGRANS. This fagræa, in Tenasserim, yields a very hard and excellent timber, which Mr. O'Riley says the teredo will not attack. The Burmese regard it as too good for the laity, and say it ought to be confined to sacerdotal purposes. At Tavoy, it is used principally for the posts of Buddhist edifices —*Mason*. Dr. Wight figures. Fagræa Coromandelina, 1316; Malabarica, 1317; and Zeylanica, 1317;

(3565) FALCONIDÆ, Leach's name for a family of Raptorial Birds, or birds of prey (Raptores of Illiger). In this family the destructive power is considered by all zoologists to be most perfectly developed; and we find in the birds composing it natural instruments for striking trussing, and dissecting their prey, combined with a power of flight and strength of limbs equivalent to the necessities of the case, whether the prey be aerial, that is, whether it be the habit of the raptorial bird in question to strike down its quarry while the latter is in the act of flight, or whether the prey be terrestrial, or, in other words, captured on the ground.—*Eng. Cyc.* See BIRDS OF ASIA.

(3566 FALSA, *Grewia Asiatica*.

(3567) FANAM, a small silver coin, the 1-12th of a rupee formerly current in the Carnatic: no longer coined.

(3568) FAN PALMS, the Chamærops humilis Linn: used for this purpose grows in considerable abundance on the shores of the Mediterranean. The leaves of many of the palms of southern Asia, the Corypha and Date palms, are similarly employed.

(3569) FANS of China are principally exported to the United States; a few go to India and South America. Those sent abroad are made of palm leaf and paper; feather and silken ones are not so often shipped Fire-screens are included under this head as well as fans; these are lackered. In 1836-7, 171,143 fans and five-screens were shipped to America, at $1½ per thousand, and 2,200 feather fans to 40 cents each. According to the old duty, 100 fans paid 1½ mace duty. The greatest part of the fans sent abroad are those which do not fold up.—*Morrison*.

(3570) FARINACEOUS FOODS, those sold in London and their composition, etc.*

Gardiner's Alimentary Preparation.—Consists entirely of rice, reduced to the state of an extremely fine powder which crepitates, under pressure, in the same manner as do most of the arrowroots.

Leath's Alimentary Farina, or Homœopathic Farinaceous Food.—Consists principally of Wheat flour, slightly baked, and sweetened with sugar, together with Potato-flour, and a very small quantity of Indian-corn meal and tapioca.

Semolina.—Consists of the gluten of wheat, with a certain proportion of the starch, part of this having been removed. Semolina resembles in appearance sago but the little granules of which it is composed in place of being round as in sago are angular. When moistened the water is rendered perceptibly opaque and milky by the starch still present and the fragments swell up and become soft and glutinous. Semolina is not a proprietary article, it is kept by most corn chandlers and many grocers and oilmen.

Prince Arthur's Farinaceous Food—Consists entirely of Wheat Flour slightly baked.

Prince of Wales' Food—Consists entirely of potato Flour.

Hard's Farinaceous Food.—Consists entirely of wheat-Flour baked.

Maidman's Nutritious Farina—Consists of Potato flour artificially coloured of a pink or rosy hue the colouring matter probably being Rose Pink.

Bradense Farinaceous Food—Consists of wheat-flour baked.

Jones's Patent Flour—Consists of wheat-flour with Tartaric Acid and Carbonate of soda.

Soojee—Consists of Wheat Flour sweetened with sugar. Baxter's Compounded [illegible] consists of Wheat Flour sweetened with sugar. [illegible]'s Improved Farinaceous Food consists principally of Bean or Pea-Flour, most probably the former, with a little Tuca, Arrow-Root, some Potato-Flour, and a very little Maranta Arrow-Root.

Vitaroborant.—Consists of a mixture sweetened with sugar of the Red or Egyptian Lentil and Wheat-Flour, the latter in considerable amount. Vitaroborant bears considerable resemblance to Du Barry's Revalenta and is sold at 2s. per pound,—*Food and its adulterations*, *p.* 250.

(3571) FARFUGIUM GRANDE. Mr. Fortune says at Ningpo, in the garden of an old Chinese gentleman there, he met with a beautiful new herbaceous plant, having rich blotched or variegated leaves which has since been named as above by Dr. Lindley. It was growing in a neat flower-pot, and was evidently much prized by its possessor, and well it might for it was the most striking looking plant in his garden. He informed Mr. Fortune that he had received it from Peking the year before, and that at present it was very rare in Ningpo, but he thought his visitor might be able to procure a plant or two from a nursery-man in the town, to whom he had given a few roots. He lost no time in paying a visit to the nursery indicated and secured the prize. It has reached England in safety, and will shortly be a great ornament to the houses and gardens there.—*A. Res. among the Chinese p.* 420.

(3572) FEATHERS, (Bed.)

Bedveern, Pluimen, Dut.	Par, Guz Hind.
Plumes, Plumes a lit, Fr.	Piume, It.
Federn, Bettfedern, Ger.	Plumas, Sp.

Are procured from common poultry; but the most esteemed, however, are those of the goose, which are best when plucked from the living animal. They are used for beds, pillows, &c.—*Faulkner*.

(3573) FEATHERS. The preparation of the feathers of various birds for ornamental purposes forms the art of the *plumassier*, the French term for the artisan who works on them and combines them into their various forms, according as they are wanted for military use, or for purposes of the toilette. The feathers most esteemed in Europe are those of the ostrich, which are accordingly imported from the African shores in considerable quantities. The west of Europe is chiefly supplied from the northern margin of the Great Desert. Those plucked from the living animal are far more beautiful, as well as more durable, than those taken from the animal some time after death. But the feathers obtained from recently killed birds have the same qualities as the living ones, and are far superior to the cast or dropped feathers. The plumage of the male bird, as is generally the case in all varieties of the feathered race, is very superior to that of the female, the fine drooping plumes on the back and near the tail being of the purest white, while those of the female are never free from a tinge of grey near the tip. In preparing the feathers for use, they are first tied together in bundles, plunged into tepid soap-and-water, and rubbed with the hand to free them from grease. After remaining in it for a few minutes, they are washed several times in pure water, as hot as the hand can bear, to rid them of the soap. Then they are bleached by being placed for a quarter of an hour in boiling water, holding in solution Spanish-white, the solution being frequently agitated during the time, and the feathers washed in pure water on their removal. The next process is to pass the feathers quickly through a bath of cold water tinted with indigo, and the final one consists in sulphuring them in the same way as straw hats are done, and then hanging them up to dry. The ribs of the feathers are scraped to render them pliant, and the filaments are curled by drawing the edge of a blunt knife over them. Feathers are made to take a variety of beautiful colours, and of these rose colour is given with safflower and lemon-juice, and deeper shades of red by a boiling bath of Brazil wood, and subsequently a bath of cudbear. Indigo supplies the blues, and turmeric the yellows, alum being the usual mordant. Various shades are obtained by mixtures of the above dyes in different proportions. Besides the ornamental purposes to which feathers are applied, there are highly useful ones, of which we all reap the benefit in the comfortable beds they supply, and in the facility with which their quills are converted into organs of communication. For bed feathers, those of the goose are employed, being dried in the air, in the sun, or in an oven, and also beaten many times. The down of the eider duck, a bird which is only found in northern countries, is remarkable for its lightness, and is very valuable for making quilts; but this down should never be employed for sleeping on, as it thereby loses its elasticity. Goose feathers unite all the qualities required in beds, namely, softness, elasticity, lightness, and warmth. After long use it becomes necessary to purify the feathers which have been used for beds, but this cannot be done by washing, as with wool or cotton. Sometimes they are put into large metal cylinder, the double end of which receives the fire, and then agitated with sticks and beaten in order to be employed again; this operation, however, dries the feathers very much. A much better mode of purification consists in keeping the feathers moving in rotation, during a convenient time, in a cylinder with double partitions, between which steam is introduced. The feathers are exposed during several instants

to the action of the steam of water and are then dried by simple exposure to the air.—*Tomlinson.* Commercially is celebrated for its feathers. They are either prepared singly for head-dresses, or made into tippets, boas, and muffs, some of them are exceedingly beautiful and apparently not inferior in quality to those imported into Great Britain from Africa.—*Mr. Taylor.* The Down of the young Adjutant Crane (Ciconia Argala) and of other cranes, are made into Ladies' Boas and Victorines. The Adjutant is very rarely found in Southern India, but a kindred species the Ciconia alba, (Jerdon) is pretty common. Of this the under tail coverts are collected and sold in considerable quantity. Many are procured at Trichoor in Malabar.—*M. E. J. R.* In Madras, of all the dealers in bird's feathers, Hoossain Saib is the only person now remaining: he lives in Anguppah Naik's street, Black Town, and carries on this trade on an extensive scale:—he has nearly 100 sets, each composed of 4 or 5 shikarees and one cook—most of these people are koravahs (basket makers) who live in and about Madras. Each set has its head man who is responsible for the others. These sets are sent out once a year, each receiving from 20 to 100 Rupees together with a certain number of nets, a knife &c.—they traverse various countries between Bombay, Delhi, Benares, Calcutta and all over the Deccan, collecting the feathers of the birds (king-fishers) and return after 6 or 8 months to Madras (each set bringing from 1000 to 6000 feathers) i. e. according to the amount they receive; they deliver the feathers to the Merchant who settles their accounts, at once, rating them at 14 Rupees per hundred and they then return to their houses and do not go out for the next 6 months. The Merchant subsequently watches for an opportunity to dispose of the feathers at Madras to the Birmese and, if he fails here, ships them off to Penang, Singapore and Malacca, and sometimes direct to China, where they are much required and sold at 10 or 13 dollars per cent. The whole of the shikarees have their families who receive monthly allowances in the absence of their husbands, brothers, fathers &c. They are trustworthy people, because the merchant trusts to their simple agreement and pays them any sum they require.—*Madras Central Committee for Exhibition of* 1851.

(3574) FELIDÆ, or FELINA, a Family of the Cat kind, of the order *Carnivora*, in which the organs of destruction reach their highest development. They are, among the quadrupeds, what the *Falconidæ* are among the Birds. Sometimes this family is made to include the Dogs, Hyænas, Wolves, and smaller *Carnivora*. We shall confine ourselves here to the members of the tribe *Felina* of Dr. J. E. Gray, comprising the Cats, Lions, Tigers, Leopards, and Lynxes. The principal instruments of the destructive energy of these animals are the teeth and claws. The dental formula in these animals is the following:

$$\text{Incisors, } \frac{6}{6}; \text{ canines, } \frac{1-1}{1-1}; \text{ molars, } \frac{4-4}{3-3} = 30.$$

It will be advantageous to be put in possession of M. Temminck's well-considered and digested monograph of the genus *Felis*, divided into two sections, according to their geographical distribution.

Section 1.

This comprises the *Felidæ* of the Old Continent and its archipelagos.

Species.

Felis Leo, including the three varieties of Barbary, Senegal, and Persia.

Felis Tigris, the Royal Tiger.

Felis jubata, the Hunting Leopard.

Felis Pardus, the Panther. Of this M. Temminck gives the following character:—When adult, less than the Leopard. Tail as long as the body and the head, its extremity when turned back reaching to the tip of the nose; colour of the fur deep-yellowish fulvous, its internal parts marked with rose-like spots of the same hue as the ground-colour of the fur; the numerous spots closely approximated; the rose-like spots from 12 to 14 lines at the utmost in diameter; caudal vertebræ 28.—N. B. The number of caudal vertebræ assigned to the Leopard by M. Temminck is 22. It would appear that there is no correct figure of the true Panther. The Black Tiger, *Felis melas*, Riman Kumbang of Sir Stamford Raffles, is considered as only a dark variety of the Leopard.

Felis macrocelis, the Rimau-Dahan.

Felis cervaria, the Lynx.

Felis Catus.

Felis maniculata.

Felis minuta, identical with the *F. Javanensis* of Horsfield's 'Zoological Researches in Java,' and therefore not to be adopted.

Felis Leo, var. *Goojrattensis*, Smee; *F. Leo*, Linn, Morocco, Nubia, Ushantee, Mozambique,	Lion.
Felis Tigris, Linn. Goa, Baroda, Bengal, ...	Tiger.
Felis Pardus, Linn. Western Africa, South Africa, Ceylon, India, Malacca, ...	Leopard.
Felis jubata, Sch. Nubia, South Africa, India, ...	Cheetah.
Felis macrocelis. Java, ...	Riman-Dihan.
Felis viverrina, Bennett. Bengal, ...	Wagati.
Felis Chaus, Guldenstedt. Egypt, ...	Marsh Cat.
Felis Caracal, Schreber. Gambia, Bombay, Nubia, ...	Caracal.

Eng. Cyc.

(3575) FELSPAR, a Mineral which occurs in very part of the earth, and is one of the consti- uents of granite. It occurs crystalline and mas- ive. The primary form of the crystal is an ob- que rhombic prism. Colour white, [illegible] ed, of different shades. Trans[illegible] hat, or opaque. Lustre vitreous, [illegible] ity 2·5 to 2·6. Hardness, 6·0. [illegible] h-white. Cleavage parallel to the terminal lane and oblique diagonal.—*Eng. Cyc.*

(3576) FENNEL FLOWER. NIGELLA SATIVA. Lin.

arin Serigum, TAM.	Nulla zilakara, TEL.
olunjan, ARAB.	Calonjira, HIND.
oonecz, ARAB.	Mangvi, SANS.
eadanch, PERS.	

This aromatic seed is used by the Native Practioners of Southern India, in cases of indigestion d in certain bowel complaints, it is also prescribed as an external application, when mixed th gingelie oil, in eruptions of the skin. The tives have a notion that, when put amongst their en, it keeps away insects.—*Ainslie's Mat. Med.* 15. In Tenasserim, the seeds of this plant, hich were formerly used for pepper, are valued the inhabitants for their carminative proper- s, but the plant is rarely seen in cultivation. he Hebrew word, which in Isaiah is rendered *ches* designates this plant; but not in Ezekiel here the original word for fitches signifies spelt, species of wheat.—*Mason*

(3577) FENNEL FLOWER OIL. NIGELLA TIVA.

Carun Seeragum, TAM.	Kulanjee and Siah danah,
Nulla Gilikarra TEL.	HIND.

The black aromatic seeds of the nigella sativa ld by expression a dark colored fragrant oil. -*Madras Exn. Ju. Rep.*

(3578) FENNEL SEED, SWEET. ANETHUM FŒNICULUM, Lin.

zeeanuj, ARAB.	Adas JAV.
wadooreo, CYNG.	Badeeyan, PERS.
nf, DUK.	Madhurika SANS.
nouil, FR.	Perun-Siragum, TAM.
urrialee, Maytri, Guz, & HIND.	Pedda-gillakara, TEL.

The fragrant, warm, aromatic seeds of the eet fennel, which are much used by native ctitioners as a carminative and stomachic. e plant is cultivated in Bengal, in some parts the Bombay Presidency and in great abun- nce in many parts of India. The Natives use as we do, as a carminative and stomachic: by ropeans as well as Natives, it is apt to be ufounded with Anise seed, which is very scarce the southern parts of the Peninsula, and the khanie name for both is the same.—*Ainslie, t Med. p.* 16.

(3579) FENUGREEK. TRIGONELLA FŒNUM GRŒCUM,

Vendium, TAM.	Methee, HIND.
Menthiloo, TEL.	

(3580) FENUGREEK SEED.

Holbeth, ARAB.	Methee, Methee, Guz. Hind.
Methesha, PERS.	Menthi, PERS.
Menta-Sagra, Methi, Guz.	Methee, Port.
Oolowa, CYNG.	Methee, Rus.
Methee, DUK.	Methee, SPA.
Fenugrek, FR.	Methee, TAL.

These seed have rather an unpleasant odour, with an unctuous farinaceous taste, accompanied with a degree of bitterness. They are much used by native practitioners in dysenteric complaints; and also as an ingredient in curries. The plant is a native of the South of Europe, and is cultivated in Asia-minor, and India.—*Faulkner.*

(3581) FERNS, the common name for a group of Cryptogamous Plants. [FILICES; DANÆACEÆ; LYCOPODIACEÆ; POLYPODIACEÆ; MARSILEACEÆ; OPHIOGLOSSACEÆ.]—*Eng. Cyc.* The rhizome of *Pteris esculenta* is used as food in Australia, and that of *Marattia alata* in the Sandwich Islands. The trunks of the *Alsophila*, or tree fern, of the western side of Van Diemen's Land, and of the common tree fern, *Cibotium Billardieri* (the *Dicksonia antarctica*, of Labillardiere), contain the edible pith or bread-fruit eaten by the natives. Many other species of ferns are esculent. Typha bread is prepared in Scinde from the pollen of the flowers of the *Typha elephantina*, and in New Zealand from another species of bulrush (*Typha utilis*). "It must not be supposed, as some have believed, that the fern root, wherever it grows, is fit for food On the contrary, it is only that found in rich loose soils which contains fecula in sufficient quantity for this purpose: in poorer ground the root contains proportionally more fibre. We were now encamped on an alluvial flat in the valley of the river, thirty or forty feet below the general level of the plain; and I observed that, even in this favourable spot, a great deal of discrimination was used in selecting the best roots, which was discoverable by their being crisp enough to break easily when bent: those which would not stand this test being thrown aside. Here a quantity sufficient for several days was procured, and was packed in baskets, to last till another spot equally favourable could be reached."—*Simmonds.* Mr. Royle informs us that many of these articles are still used in medicine in India. The rhizomes, or dried leaves of *acrostichum*, are sold under the altered name, *Iskoolikundriqon*. Those of Polypodium are called *bulookunboon*. The Asplenium *radiatum*, *morpunkhee*, or peacock's fan, is employed by the natives probably as an anthelmintic. The *Adiantum capillus veneris*, or Venus' hair, is indigenous in the Himalayas, where it is called *zhuer-ul-jin*, or fairy's hair. *Moolaithee* and *hungraj* are also applied to several Indian. European article it is given as an expectorant. In Europe it is the basis of the celebrated *Syrop de Capillaire*.—*O'Shaughnessy, page* 977.

Botrychium virginicum,—Is a large succulent fern which grows plentifully in the Jaldhaka Pass in the Sikkim Himalayas; it is boiled and eaten, both there and in New Zealand. Indeed ferns are more commonly used for food than is generally supposed. In Calcutta, the Hindoos boil the young tops of a *Polypodium* with their shrimp curries; and both in Sikkim and Nepal the watery tubers of an *Aspidium* are abundantly eaten. So also the pulp of one tree-fern affords food, but only in times of scarcity, as does that of another species in New Zealand (*Cyathea medullaris*); the pith of all is composed of a coarse sago, that is to say, of cellular tissue with starch granules.—*Hooker Him. Jour.* p. 292. Ferns are among the most curious objects in the vegetable kingdom, and numerous species are indigenous in the Tenasserim Provinces.

Polypodium giganteum,—A tree fern, is very rare but is occasionally seen in the southern Provinces, resembling a small palm. Griffith found the same species in Assam. The natives have but one name for both the cycas and tree fern.

Lygodium scandens. Ophiglossum scandens,—Climbing ferns. One of the most elegant climbers on the Tenasserim Coast is a terrestrial species of fern, easily recognized by its habit of running over other plants, and by the fringed margin of its leaflets, from which it is sometimes called "fringed fern." An allied species is found in the United States.

Polypodium quercifolium.—Oak-leaved polypod. In some parts of the forests of Tenasserim the trunks of almost every tenth tree have a great abundance of a large species of polypod growing upon them. The barren fronds are cordate, and stemless; but the fertile ones stand on long slightly winged stems, and are gashed like the leaves of an English oak.

Polypodium pertusum,—Pitted polypod. In Tenasserim, this fern is often found in company with the preceding species; and may be easily recognised by its creeping habit, and by the margins of the upper parts of its fronds being rolled together when in fructification.

Polypodium,—Reed fern. This is a large terrestial fern with hollow stems like a reed, which are often used by the natives of Tenasserim instead of quills for pens.

Pteris amplexicaulis,—Stipe-clasping brake. A large brake is common at Tavoy with pinnate fronds, whose leaflets have two lobes at the base which clasp their stripe.

Pteris graminifolia,—Grass fern. The trunk of forest trees in Tenasserim are often clothed with the green drapery of the grass fern, which grows upon them precisely like bunches of long grass. It belongs to the same genus as the common brake.

Davallia,—Davallia. An elegant fern of the genus davallia, characterized by the fructifications being "in roundish separate spots, near the margin," is very plentiful in the neighbourhood of Maulmain.

Hemionitis cordifolia,—Male fern. Near the sea shore, in Tenasserim, a species of male fern with cordate fronds is sometimes seen.

Lomaria scandens,—Scandent lomaria. The low lands near the mouths of rivers and nullahs in Tenasserim are often fantastically dressed with a species of lomaria which creeps up to the tops of the tallest trees.

Tænis blechnoides?—Tapeworm fern. The tapeworm fern, so called from the resemblance of the line of sori to a tape worm, is not infrequent in Tenasserim.

Adiantum,—maidenhair. A small handsome fern is seen in Tenasserim, in the crevices of old ruins and walls every where, of the same genus and nearly resembling the English maidenhair—"the prettiest of all ferns."

Lycopodium,—club moss. The green woods of the Tenasserim southern provinces are often carpeted with the club moss, or ground pine, of which we have one or two handsome species.

Salvinia cucullata,—salvinia. A curious little floating plant, related to the ferns, of the genus salvinia, is often seen on the surface of old tanks and stagnate waters in Tenasserim.—*Mason.*

(3582) FERONIA, the name of a genus of Plants belonging to the natural order *Aurantiaceae*. The flowers are often polygamous. The petals are usually 5 in number, occasionally 4 or 6, spreading. The calyx is flat and 5-toothed. Stamens 10; filaments dilated and united at the base; anthers linear-oblong, tetragonal. The ovary is seated on the elevated disc, 5 or occasionally 6-celled; ovules numerous in each cell. It has scarcely any style and an oblong stigma. The fruit is inclosed in a hard rind, 5-celled and many seeded, which seeds are immersed in a fleshy pulp. The leaves are pinnated with from 5 to 7 leaflets nearly or quite sessile, very slightly crenulated, with pellucid dots along the margin, inconspicuously dotted elsewhere: the racemes are axillary, terminal, and few-flowered.—*Engl. Cyc.*

(3583) FERONIA ELEPHANTUM. Wood apple Capitha, As. Res. vol. iv. p. 283.

Koit, HIND.	Bilvurthiththa maru, CAN.
Veela maram, Vellanga, TAM.	Vellaga betlen, TEL.
	Cavita Vrikshe, CAN.

F. Elephantum is the Elephant-Apple or Wood-Apple of the Coromandel coast, where it is very generally eaten. The branches of this tree are armed with small spines. The leaflets which vary in number from 5 to 7, are small obovate and smooth; when very young they are

lin, and when bruised have a most fragrant mell resembling anise. The native practitioners f India consider them stomachic and carminative. fter a certain age however, the leaves become ough and almost coriaceous. The fruit is highly ed extremely acid before it arrives at maturity, n when ripe, it contains a dark brown agreeble subacid pulp. In appearance the fruit is rge, spheroidal, rugged, and often parted externally; the seeds are in five parcels, and are flat nd woolly, adhering to the branched placentæ y means of long cords. A transparent, oily uid exudes from the trunk of this tree when an cision is made into it, which is used by painters r mixing their colours. A clear white gum ay also be obtained from the tree very much sembling gum-arabic. The wood is likewise luable on account of its durability, whiteness, d hardness.—*Eng. Cyc.* It is a large tree nd in most parts of India. Both leaves and wers have a strong odour of anise. The young ves are used by native practitioners as a genstomachic stimulant in the bowel complaints children. A large quantity of gum (*karil ka ed*) is procured from this tree. It very much sembles gum Arabic in its chemical and sensie properties. The babul tree also furnishes uch of the gum found in the Bazars. The nim, ngo, cassia auriculata, cotton tree, and several hers, yield this principle, and the products of are mixed for sale by the native druggists, as m arabic.—*O'Shaughnessy, page* 333.

(3584) FERRIOLA BUXIFOLIA.

Croombala, Eng. | Hoombully marum. Tam.

This plant grows among the Circar mountains be a small tree but in the low countries it is ly a shrub. The berries of this tree are unirsally eaten when ripe, and are very well tast-. The wood is dark colored, remarkably hard d durable; it is employed for such uses when size will admit, as require the most durable avy wood.—*Rhode, M.S.S.* Its fruit is pleasant the taste and is well known over all the lower ovinces of India. It is a small red fruit conning one seed.—*Ainslie, p.* 224.

(3585) FERULA, a genus of Plants belongto the natural order *Umbelliferæ*, whose spes often yield a powerful stimulating gum resin ployed in medicine. It differs from *Pastinaca* [illegible] *Peucedanum* by its fruit having several vittæ, ach channel, and from *Opoponax*, which it erwise resembles, in the margin of the fruit ng thin and flat, not thickened and convex. e fruit is in appearance extremely similar to t of a parsnip; it is compressed from the k till it is extremely flat, and it thins away at edge. There are [illegible] filiform nal ridges, and the [illegible] are distinct, olete, or lost in the [illegible]. In each channel e are three or more vittæ, and on the commare four, or a great many. The flowers are always yellow, and the stem solid, its cavity being filled with a spongy substance, in which fibres are vaguely dispersed. The drugs called Sagapenum and Assafœtida were supposed to be produced by species of this genus, but by which in particular it was not known with certainty. Dr. Falconer has shewn that Assafœtida at least is produced by another genus, which he calls *Narthex*.—*Eng. Cyc.*

(3585) FERULA ASSAFŒTIDA, is found in only two districts of Persia, namely, the fields and mountains of Herat, the capital of Khorassan, and the range of mountains in the province of Lar (Laristan), extending from the river Curus far as the town of Congoon, along the coast of the Persian Gulf. Kæmpfer states that even here the plants do not always yield the drug; that it is only those of the desert near Herat and of the mountains round Disgunn in Laristan that furnish it; and he figures a plant, with a naked simple stem, clothed with leafless sheaths, umbels without involucre, a coarse woody root rising above the ground, and pinnated leaves with pinnatifid segments and oblong obtuse lobes. This plant is the *Ferula Assafœtida* of Linnæus and De Candolle; what is supposed to be it has since been met with in Beloochistan, and Lieutenant Burnes saw what he calls *Assafœtida* growing in great luxuriance in the mountains of Hindoo-Koosh at an elevation of 7000 feet. He states that it is an annual, and grows to the height of 8 or 10 feet, when it withers and decays. The milk which it exudes is first white, and then turns yellow and hardens, in which state it is put in hair bags and exported. Sheep browse upon the tender shoots, which are believed to be highly nutritious. ('Travels,' ii. 243.) It is however by no means certain that this was true Assafœtida. Indeed if it was, as Lieutenant Burnes states, an annual, it must have been some other plant; for Kæmpfer expressly describes the root of Hingiseh, or Assafœtida as "ad plures annos restibilem, magnam, ponderosam, nudam," and in fact it is from wounds in this root that the gum-resin flows. It is probable that Assafœtida is yielded by different plants. Professor Royle obtained seeds of two kinds from the bazar of India; and it appears from a communication made to Mr. Macneil from a medical gentlemen at Sooneeana in Beloochistan, that in that province a kind of *Ferula* called Hoosbee yields a similar product, which however is not collected. The F. *Assafœtida* is said to arrive at as great an age as man himself, and in consequence its roots sometimes attain a considerable size. It is from wounds in this part that the drug is obtained. The roots are not wounded before they are four years old, the greater their age the better the quality of their produce. There were four operations each year when Kæmpfer visited the country; the first in the middle of April, the second at the latter end of May, the third ten

days later, and the fourth in the beginning of July. The gatherers on the first occasion only cleared the hard sandy or stony soil away from the root to the depth of a span or so, pulling off the leaves, replacing the earth about the roots, and then heaping the leaves on them, pressing them down with a stone. On the subsequent occasions they slice the roots transversely, beginning a little below the top, and collecting the juice that flows from the wounds. After every operation they cover the root with the old leaves to screen it from the sun. After the last gathering the screens are thrown away and the roots are left to perish. Dr. Falconer believes his Narthex Assafœtida to be identical with Kæmpfer's plant.—*Eng. Cyc.*

(3587) FERULA FERULAGO. *Syn.* F. galbanifera, (Nees and Ebermaier.) Coasts of the Mediterranean, the Caucasus, &c. yields copiously a secretion which dries into a gum resin, supposed to be galbanum. Although *F. ferulago* has been taken for the plant which furnishes galbanum, Professor Don states that this drug is really yielded by quite a different genus, called by him *Galbanum officinale.*—*Eng. Cyc.*

(3588) FERULA HOOSHEE. Beloochistan. Resembles the asafœtida in size and appearance, and yields a gum like the opoponax of the European shops, (*Mrs. M'Neil's letter*, 1833.) Professor Royle alludes to this also as resembling opoponax.—*O'Shaughnessy, page* 364.

(3589) FERULA ORIENTALIS, Feshook, *F. ammonifera.* Fee. Has also been quoted as the source of gum ammoniacum; and it appears that such a substance is really produced, either by that plant or a nearly allied species, in the Empire of Morocco.—*Eng. Cyc.* It grows in Asia Minor, Greece, and Morocco.—*O'Sh. p.* 364.

(3590) FERULA PERSICA. *Syn* F. Sagapenum. Fee, vol. ii. p. 201.

Sugbeenj, Arab. | Kundel, Hind.
Sugafioon, Pers. & Greek.

Persica, a perennial species with a glaucous stem and suprade-compound leaves with linear cut segments, has been reported to yield assafœtida. Dr. Hope entertained this opinion, from which Nees and Ebermaier do not dissent. Treviranus found it yielding a substance extremely like assafœtida in the botanic garden of Breslau; and the same thing has often occurred in the Apothecaries' Garden at Chelsea. Nevertheless, Fee suspects, after Willdenow, that it is rather the origin of sagapenum. Olivier believed it to produce gum ammoniacum: but according to Professor Don that drug is yielded by his *Dorema ammoniacum.*—*Eng. Cyc.* A native of Persia, stem about two feet high. According to some authorities it produces Sagapenum. Nees von Esenbeck and Lindley consider it as one of many plants from which asafœtida is procured.—*O'Shaughnessy, page* 363. *Sagapenum*, is found in masses formed of soft, adhesive fragments the size of the thumb or more, somewhat transparent, reddish yellow externally, pale within, of waxy or brittle consistence, often mixed with impurities and seeds. Its odour resembles that of garlic and asafœtida, its taste is hot, nauseous, and rather bitter. It is sometimes adulterated with bdellium, gundabirosa, and other similar gum resins or turpentines. Sagapenum is totally soluble in weak spirit. It softens under the fingers, becomes tenaceous, and melts at a low temperature. It is collected in the same manner as asafœtida; in the Bengal bazars small quantities are procurable at the rate of four rupees the lb. The medical uses of Sagapenum are the same as those of asafœtida, but it is considered less energetic, and is but little employed.—*O'Shaughnessy, pp.* 363-64.

(3591) FIBRES AND FIBROUS PLANTS. Botanists have for some time arranged all plants into a few large divisions, from characters derived from their internal structure: thus, some being composed of cells only, are called *Cellular*; others are called *Vascular*, because, in addition to cells, they also contain vessels usually accompanied by woody tissue. The cellular tissue being developed in every direction, is sometimes called the *horizontal* system, while the vascular growing vertically, is distinguished as the *longitudinal* system. It is in this direction that the fibres of which we have to treat are placed in the plant. The development and arrangement of these two systems produce three distinct forms of growth and of internal structure. *Acrogens*, or summit growers, are so called from the growth of the stem taking place by the junction of the bases of the leaves at the top of the stem, as in Tree Ferns. Under this—used as a general term—cellular plants, such as Mosses, &c., are included; but none of them yield fibre, either for cordage or for textile purposes, though it is possible that some of the ferns contain fibre enough to form pulp for paper-makers. *Endogens*, or inside growers, are so called because the bundles of vessels and fibres proceed from the bases of the leaves into the cellular centre of the stem, and are thence pushed outwards by the new growths, so that the outside of such stems, as of Palms, is harder than the inside. These plants have no regular bark which can be stripped off, and their leaves have the veins running parallel to each other. It is these leaves which abound in fibre, which may be separated by simple pressure and washing, as in the Pine-apple, Agave or American aloe, Plantain, and many others. In Palms, the structure of the leaves is too dense for the fibres to be separated so easily. *Exogens*, or outside growers, are so called from additions to their stems being made on the outside of the growth of former years, as seen in

the rings of wood on a transverse section of the trunk of any of the ordinary trees of Europe. There is also a distinct bark of which the outer part is composed of cellular, but the inner contains the woody tissue. From this the fibres are separated for various economic purposes, usually by stripping off the bark and then steeping it in water, as with Flax and Hemp, Jute and Sunn. The leaves of Exogens have a reticulated or net-like, instead of a parallel venation. The above characters, taken from the parts of vegetation, are found to be accompanied by others equally characteristic, in the parts of fructification. Thus the spores of Acrogens, in germinating, are unaccompanied by anything like a leaf: the Endogens have a single seed-leaf, as may be seen in Wheat and other Cereals, as the Rice; while Exogens, in sprouting, display two of these seed-leaves, as in Peas and Beans. From these peculiarities other names are given to the above divisions, but which it is needless for our purposes to notice.—*Royle, Fib. Plants, page* 28. Dr. Hunter mentions that under the head of Endogenous plants yielding fibres may be classed the

Palms.	Musa or Plantain.
Aloes and Agaves.	Pandanus or screw pine.
Yucca or Adam's Needle.	Rushes.
Sanseviera, or Marool.	Grasses.
Fourcroya, or gigantic Aloe.	Sedges, &c.
Ananassa or Pine Apple.	

The Exogenous fibrous plants embrace those yielding Cotton and silk cotton, Flax and its substitutes, viz.:

Calotropis, or yercum.	Bendee, or Abelmoschus.
Sylophora asthmatica.	Toothee, or Abutilon.
Cryptostegia grandiflora, or Palay.	Barks of Trees, including varieties of Ficus.
Sæmia extensa, or Ootrum.	Bauhinia.
Hemp—Cannabis sativa, and its substitutes.	Grewia.
Jute, Corchorus olitorius.	Dalbergia.
Sunn or Junapum, Crotolaria juncea.	Isora.
Ambaree, or Hibiscus cannabinus.	Butea.
	Vernonia, &c.
	M. E. of 18.. *Juries Report.*

Preparation of the fibre of Endogens.—Though both the stem and the leaves of Endogens abound in fibre, it is from the latter chiefly that this is separated for practical purposes. The fibres of some plants are not separated from the rest of the vegetable matter, but the stems and leaves are simply dried and twisted, as in the case of some Grasses, Sedges, Rushes, and even the leaves of Palms. The leaves of others are simply beaten with a stone on a flat board or on another stone, and afterwards the rest of the vegetable matter washed away. Occasionally such fleshy leaves have been passed between rollers, as those of a sugar-mill, and with the consequent saving of both time and labour, also with diminution of cost. Very frequently, however, these leaves are steeped in water until fermentation takes place, when the labour of separating the fibre is much diminished. But this often

FIBRES AND FIBROUS PLANTS.

takes place with great loss of strength as well as of the beautiful white colour, for which most of these endogenous fibres are particularly distinguished. Dr. Hunter, who has paid much attention to the separation of this class of fibres, has observed that the ordinary modes of separating the fibres of plants in India, that is, steeping them in water, are exceedingly faulty. Every day's steeping of a vegetable substance in water takes from its strength, and communicates a tinge to the fibres, which can only be removed by the subsequent application of some chemical agent, such as lime, the alkalies or chlorine, which in some cases, no doubt, diminishes their strength. He observes that in most parts of India the fermentation which takes place in plants heaped together or steeped in water proceeds so rapidly, that it is extremely difficult to prevent the accession of putrefactive decomposition. This, he says, commences, in succulent plants, when immersed in water, in twenty or twenty-two hours, during warm weather. The sooner, therefore, that the decomposing parts of a plant—that is, the mucilaginous, saccharine, and other constituents of the sap and pulp—are removed, the whiter are the fibres, and they retain more of their original strength. The fibres cleaned within a day or two after the plant or leaf had been cut, were found to be white, strong, and silky. On wetting the same repeatedly and exposing them to the dew, it has been found that their strength is impaired. Those fibres that were steeped in water for a few days acquired somewhat of the color of English tow. Those steeped for three weeks became quite rotten, brown, and brittle. Dr. Hunter has further ascertained by experiment that the partial drying of the leaves or bark of plants in the sun, as recommended and practised by the natives, does more harm than good, as it makes the process of cleaning more tedious, and is apt to tinge the fibres. Such as have been thoroughly dried in the sun before being cleaned, give brittle and often brown-coloured fibres, unless there be naturally very little moisture to be dried up. The only way he found of preparing fibres by rotting, is that followed by the natives in a few localities near large rivers, where the leaves of the Agave, from their outside hardness, are sometimes buried under wet sand below the level of the water in the river.—*Royle's Fibrous Plants.*

General Observations on the fibre of Endogens.—The veins of this class are parallel, and not reticulated; also, arranged longitudinally, as are likewise the woody fibres; and all so regularly, that if these leaves were to grow together round the central flower-stalk, they would form rings of woody and vascular tissue, much as we see in Exogens or, indeed, in the different species of Musa or Plantain, in which the rings seen on the transverse section of the so-called stem, are actually formed by the encircling of the flower-and fruit-stalk or core by the sheath-

ing foot-stalks of the leaves. Hence, to separate such fibres, simply scraping with a piece of wood, or beating between two stones, is sufficient. Therefore, passing them between rollers, such as those of the common cotton *churka* of India, if enlarged, or those of a sugar-mill, would not only be efficient, but economical. Whether these rollers should be plain or grooved must be ascertained by experiment, and will depend, in some measure, upon the external hardness of the leaves, or their more or less fleshy nature; as this might soon fill up the grooves. Motion might be given to such cylinders, either by the Archimedean screw, cog-wheels, or by bands, moved by hand, or by bullock-or horse-power as practised in the cotton-cleaning machines and sugar-mills of different parts of India. Careful washing of the separated fibres is essential, in order to get rid of the adhering mucilaginous or other matter and the cellular texture, but the boiling in an alkaline ley may probably be dispensed with, as it does not seem to be practised in all places. But steeping in water, followed by fermentation and decomposition, is followed in some of these localities, and no doubt facilitates the separation of the fibre, at the expense, sometimes, of its strength, as well as of its colour. Careful drying cannot be omitted, as, if packed up in a moist state, fermentation followed by complete destruction would ensue. The characteristic of these fibres generally, is that they are white in colour, of different degrees of fineness, and most of them capable of bearing a considerable strain, but liable to break at knots. They are, therefore, not suited to all the purposes of cordage, but admirably so to many, from strength and lightness, as well exemplified in the case of Manilla Hemp. There is, however, an unreasonable prejudice against white cordage, though its true nature can be better ascertained than when soaked with tar. From the experiments of Du Hamel and others, it appears that this substance, unless carefully washed, promotes the decomposition of vegetable fibre; and though it is undoubtedly useful at the surface when ropes are exposed to wet, there does not seem any advantage in its covering the interior. Many compositions could, no doubt, be devised, for covering the exterior, which would be efficacious in excluding wet. These fibres, though well known to the natives of the countries where the plants are indigenous, have not attracted from others the attention which they deserve, especially as they are produced in abundance, and necessarily very cheaply, as most grow in a wild state, or form the refuse of cultivation that has already paid its expenses. Almost all, moreover, are produced on the sea-coast, or in moist climates traversed by navigable rivers, and therefore could cost little for carriage. All would be valuable as affording employment for the people, and materials useful to them for a variety of purposes, if not for exportation. Both Grasses and Sedges abound as well on the banks of the Indus as of the Ganges, and might be turned to useful account. The Pine-apple abounds in Assam and the Tenasserim provinces; and on the islands near Singapore nearly 2000 acres are covered with it, according to Mr. Logan, 'Journ. of the Indian Archipelago,' vol. ii, p. 528, who recommends their cultivation for the manufacture of Pina cloth. The Moorva and the True Aloes, as well as some of the so-called "Silk-grasses" of South America, and the inner fibres of the Plantain resemble each other in fineness of fibre, and therefore of fitness for the manufacture of similar textile fabrics, which are esteemed, at least, by the people of the East, and worn by them. All may, moreover, be twisted into fine twine or cord, and the refuse form excellent materials for paper-making. The Pita or Agave, commonly called Aloe, as well as the Yucca, New Zealand Flax, Manilla Hemp and the outer fibres of other Plantains, are coarse in texture, and fitted for cordage, at least for ordinary purposes. But if we take the Manilla Hemp as an example, or the French experiments on the Pita, or its employment for naval purposes in South America, we may consider it as fitted, with ordinary precaution, for most of the purposes of cordage, as well as from its lightness for upper rigging. In the experiments made at Madras, the Agave fibre grown there certainly did not stand the trial to which it was subjected. But, the cause of this it is no easy to determine, whether owing to natural weakness of the fibre, or to the high temperature of the water in which the ropes were exposed producing fermentation and consequent decomposition. All of these, as well as the finer kinds are well fitted for paper-making, and therefore cannot fail to be always in demand. In cultivating any of these on account of their fibrous products, it is an important point to determine the proportion in which this is yielded by the several plants. In this, as might be expected, there is considerable discrepancy in the statements of different observers—some mentioning a few ounces, where others find pounds of fibre. By some, from one seventh to one tenth part of fibre has been obtained, but this will depend upon the greater or less dryness of the leaves operated upon. In the experiments upon New Zealand Flax, it was calculated that 16 cwt., or 1792 lb. of fibre might be obtained per acre. Dr. Roxburgh obtained two crops of 1613 lb., or 3226 lb., per acre of the Moorva fibre. In one statement respecting plantain fibre, it is mentioned that 600 lb. of fibre may easily be obtained per-acre in addition to the fruit, but of [illegible] upon four or five pounds per plant, [illegible] plants to the acre, calculate that from [illegible] to 2550 lb., or about a ton an acre might easily be obtained. Others, counting upon the

suckers which are successively produced, calculate upon much higher returns, which, with good cultivation and manuring, may, no doubt, be realised. But as there is danger in over-crowding, from the want of ventilation, and weakness of fibre from the thinness and delicacy of the plants which would be produced in a crowded plantation, it is safer to leave to practical experience, to ascertain the degree to which a plantation may be safely and profitably crowded. The expenses of producing fibrous materal in suitable localities, and with appropriate means and machinery, ought not to exceed from £9 to £10; and even from India, some of these fibrous productions can be landed in England for from £13 4*s*. to £16,8*s*. per ton according to difference of quality. While we have been informed by competent judges that most of the fibres, but especially the Plantain and Pine-apple fibre, are worth about £30 to £35 per ton, if sent in sufficient quantities and in a proper state. The difference in value, therefore, would easily repay any extra trouble in preparing the fibres in a careful manner, especially if we consider how cheaply Jute is grown and prepared, as has been shown in the foregoing pages. Mr. Dickson (*v*. p. 133) is of opinion that, though many of the white fibres, are fit only for rope- and twine-makers, others are suited for textile purposes, as, for instance, the Pine-apple fibre; even "for the spinning of yarn for the fine cambric manufactures in Ireland."

On the Fibres of Exogenous Plants.—We have already noted the great differences in point of internal structure, between what botanists call Endogenous and Exogenous growth, a distinction which we have shown to be useful even for practical purposes. Exogenous plants may in general be at once known even by their leaves, of which the venation is reticulated or net-like, and not parallel as among the Endogens; and therefore the fibres, united to each other in meshes, cannot be separated from the leaves for economical purposes, but must be obtained from other parts of these plants, where the said fibres lie nearly parallel to each other, as, for instance, in the bark. The peculiar structure of Exogens may also be seen on making a transverse section of the stems or branches, for instance, of the trees of European climates. There we may see rings of wood and layers of bark. But in annual stems, we see in the centre a circle of white cellular tissue called pith, and round it a layer of wood-like matter, which in some plants is called *boon*, *ergalone*. This is surrounded by layers of cellular tissue, which, examined longitudinally, form a tubular sheath, inclosing the other parts. It is in some plants composed of long tough elongated cells or fibres, which are sometimes called *bast*, and is covered externally by a delicate skin or cuticle. It is these bast fibres which are separated from the Flax and Hemp

plants, and familiarly known by these names. If we proceed to examine the transverse section of an Exogenous branch or tree, we see a number of rings, proportioned to its age. In the centre we observe the pith, which is usually small when compared with the bulk of wood. There may also be observed a number of lines, usually lighter coloured, radiating from the centre towards the circumference. These are called medullary rays, and formed of cellular tissue like the pith. This is surrounded by a longitudinal canal, which is called the medullary sheath, and contains spiral vessels. Outside of this are the rings of wood, formed of vessels and of woody tissue; those near the centre, called the heartwood, are denser and more highly coloured than those which are more external. Of these, the youngest are known by the name of sap-wood, and are those most recently formed, as all additions of wood are on the outside of the growth of previous years, in these trees. On the outside of the layers of wood, we find the part called bark, but composed also of a series of layers; of these the oldest are on the outside, and may in some trees be seen splitting and scaling off in a withered and dead state. The new layer of bark will, however, be found in the inside of all, and next to the young wood. The structure of this part can be best examined in the bark of a young shoot. It will be found to be composed of two layers of cells, which receive different names from botanists, having the delicate epidermis or cuticle on the outside; but in the inside of all, the layer consists of tough, elongated cells and vessels, and is called *liber* or *bast*. This part is very conspicuous in the Lime tree of Europe, which, by the stripping off of its bark, yields the bast of which Russia mats are made. In the East, species of Grewia, of Hibiscus, and of Mulberry, are equally remarkable for their bast. Besides the above characteristics in the leaves, wood, and bark of Exogens, we may likewise observe distinctions in their seeds and flowers, by which they may also be readily distinguished. Thus, the seeds of Exogens contain two seed-lobes, which, in sprouting, become the two seed-leaves, as seen in the germinating of Peas, Beans, Cucumbers, &c.: while in Endogens only a single seed-leaf is seen, as in the sprouting of Wheat and Barley, Rice, or the Date tree. In the flowers, also, distinctive characters may be observed; but we shall direct attention only to those of the Exogens, in which we may see the flowers composed of stamens and pistils, surrounded on the outside by floral envelopes. In some, these floral envelopes consist of two distinct kinds—the outer usually green and the inner variously coloured; both consisting sometimes of several pieces more or less united, as seen in the Flax plant, the Jute, the Hibiscus and Cotton plant, the Sunn, and many other fibre yielding plants. Or, these

two layers may be composed of the several pieces of each, or of the sepals and petals, united together into a single piece, as seen in the Convolvulus, the Jessamine, and Vinca. The last contains tenacious fibre, is allied to the old genus Asclepias, which abounds in plants yielding strong fibre, as the *Asclepias gigantea, &c.* Some plants have only a single floral covering, which may be green or otherwise coloured, as may be seen in the Hemp, the Nettle, China grass, and other fibre-yielding plants. Plants belonging to this division of the Vegetable Kingdom are the best known on account of their fibres. Of these many are remarkable for their strength and useful properties. Having lately had occasion to report on some Indian fibres, Dr. Royle was anxious to ascertain the comparative strength of several of those fibres, which were upon the whole, but little known. He therefore had equal weights and equal lengths of several of these fibres taken, their ends tied and fixed in a vice, and then the number of pounds ascertained with which each broke. In these experiments,

Petersburgh clean Hemp	broke with	160 lb.
A fibre from Travancore, called Wuckoo	„	175
Yercum fibre	„	190
Jubbulpore Hemp	„	190
China grass, from China	„	250
Rheea fibre or China grass, from Assam	„	320
Wild Rheea, also from Assam	„	345

Hemp from Kote Kangra, in the Himalayas, bore 400 lbs. without breaking.

Though many Indian fibres are possessed of all the good qualities required of such substances, objections are made to most of them. To some, that they are coarse; to others, that they are not strong enough, or that they break at knots; also, that they are incapable of fine subdivision on the hackle, or that they do not spin well, or have little twisting property on the spindle; but the greatest of all objections probably is that modifications of machinery are sometimes required for new fibres. With regard to the alleged coarseness, and that they are not capable of fine subdivision; this is, in most cases, merely a question, of preparation, which might be carried to a greater extent in India or in England, before attempting to spin them. Dr. Royle gave several of these fibres to Mr. Dickson, of Deptford, and he returned them in a few days, in a state in which he was scarcely able to recognise them, from their soft and silky, hair-like appearance; and he has little doubt but that the progress of experiment will show that this change can be effected at a comparatively small cost. With respect to their breaking at knots, this appears to be the case only with the white fibres, of which we have just treated, and which in this respect are like New Zealand Flax and Manilla Hemp. Some of the same objections were made against the Jute, when first introduced; and many years elapsed before it came to be used as it now is, and considered indispensable to the manufactures

of some localities. For instance, about 15,000 tons are annually employed in Dundee alone. Jute is certainly characterised by fineness, silkiness and facility of spinning; but it is less strong than many other Indian fibres, which are possessed of similar properties with greater strength as we hope to be able to show among the Mallow and other nearly allied tribes of plants. Among the Nettles, we hope to be able to prove that the combination of strength with fineness and capability of being spun, is as great in the Rheea fibre from Assam as in the China grass from China. When, at the end of 1854, he was endeavouring to prove that many of these fibres were fit for all the purposes of rope-making, he was equally told that they were weak, or would not twist, or not take tar. He has since had some of them made into every variety of cordage, from fine whipcord to a five inch rope, and finds that, in all cases, many exceed Russian Hemp in strength, and are therefore more than efficient substitutes. Though some practical men have stated that these Indian fibres do not subdivide, and will not spin, others are of a contrary opinion; and he refers to the statements of Mr. Dickson, published in the 'Journal of the Society of Arts.' In the then expected deficiency of Russian Hemp and Flax and looking to the sources whence consumers might obtain substitutes for them, he observes "From the experiments I have made on all kinds of fibre, I fearlessly assert that they can have a cheaper and better supply of fine and coarse fibre from India, for rope-makers and fine spinners, than it is possible for them to get from any other country, and the samples in the Society's rooms are a proof" (referring to his own and the East India House specimens then displayed there). "Dr Royle gave a very correct account of the superiority in the strength of the Himalayan Hemp compared with that of Russia; but that is not the only advantage to be gained by the importers and consumers of Hemp" "I have made the Himalayan Hemp so soft, fine, and white, that it will not only take the place of Petersburgh Flax—now £60 per ton, the best of which can only make 40s. warp yarn—but it can be used in place of Dutch Flax, at £80 per ton; and I speak from twenty years' practical knowledge, when I say it is capable of being spun into 60s. warp yarn." "The Rheea fibre, or Assam grass, when so prepared by the machines and liquid, is a finer, and consequently, more valuable fibre. It is equal in strength and fineness to China grass, at £100 per ton." "The Yercum, which very much resembles Belgian Flax, is also well calculated for prime warp yarns, and worth £10[illegible] per ton." The Wuckoo nar, Mr. Dickson places next this in another statement. "The Neilgherry Nettle is a most extraordinary plant; it is almost all fine fibre, and the tow is very much like the fine wool of sheep, and no doubt will be

largely used by wool-spinners." "The Madras Hemp, and Bombay and Sunn Hemps, will at all times command a market, when *properly cleaned out*, at £45 to £50 per ton, for twines or common purposes." In another published statement (Flax Works, Grove Street, Deptford, April, 1854), Mr. Dickson says of—"Madras Hemp, valued when imported at £24 per ton:

	cwt.	qr.	lb.
Madras Hemp, ...	2	3	3

Produced by the machines:

	cwt.	qr.	lb.
Clean, long fibre, good, valued at £45 per ton,	1	1	7½
Clean tow, valued at £30 per ton, ...	1	1	9
Waste, ...	0	0	14½
	2	3	3
Cost of Preparation, ...	6s.		1½d

"This Hemp, when prepared with the patent liquid, became soft, white, and so fine when hackled, as to bear the closest comparison with Flax at £80 per ton. It is better than any Russian Flax for fine spinning." Practical men alone can judge of practical questions, when they have made careful experiments on new products, and have laid aside all prejudices in favour of old ones. But Dr. Royle was surprised with the improved appearance and fineness of many of the coarse-looking Indian fibres; though he says he ought not to have been so, from what he had previously seen of some of these fibres. This more especially, as there is no rational reason why the varied soil and climate of India should not produce as finely divisible fibres as any produced in the short, but warm and dry summers of Russia. These fibres would, moreover, look as well in the market, if the natives of India would take the same trouble with their preparation as is done in Europe with Flax and Hemp. Natives of India do little justice to the products of their own country; for most of their fibres, like their cotton, come to market intermixed with much dust: some, moreover, almost in the state of bast, upon which freight and charges have to be paid before they can be used either for cordage or for textile purposes. Manufacturers, therefore, give a lower price for them than would be the case if they reached England in a clean and workable state. A considerable loss is likewise sustained, by what is very unusual, that is, the *extra* care bestowed on some of these fibres in different parts of India. Some are twisted into rope-like bundles; others are plaited into the form of Chinese pigtails, or tied together with knots at the ends. In this case, these ends must at once be cut off, and the fibres, thus much shortened, before they can be used. When twisted or plaited, boys and girls are obliged to be employed in untwisting and opening them out, in order to bring them to a state from which they have been needlessly removed. All that is necessary is that the fibres should be tied in convenient-sized bundles; and retained in the state in which they are removed from the plant, and that in which they must be when undergoing the different processes of preparation, that is, nearly parallel to each other. They may then be simply tied together near the thicker end, so as to form what are called *heads*: or they may be similarly tied in two or three places, if it is thought desirable to do so, with long fibres. Such fastenings can most easily be cut across with a knife, and with the least possible expenditure of time and labour; so as to expose the fibres in a state in which they can be immediately made use of. Besides this mode of tying up the bundles of fibres, which would, in fact, save much of the time and labour, now injuriously expended, it would be desirable if the native could be induced, generally, to pay more attention to the preparation of these fibres, especially in not macerating the plants longer than absolutely necessary for the purpose of separation. The benefits of such care would soon be apparent in the increased demand and improved prices for Indian fibres, not only in this country but in other parts of the world.—*Royle's Fib. Pl. page* 125. In sending Fibres to the English market, it would greatly facilitate their employment, if the natives of India would prepare them in a cleaner state, and have them made up in the manner to which manufacturers there are accustomed. Most of the Indian Fibres have been examined by practical men of skill, who consider them to be well adapted for many purposes, and have assigned to them such prices as appear to be sufficient to pay for their culture and export. The subject of Fibres has of late attracted considerable attention in India, as the Governor-General has issued instructions for the sending to England some of the stronger Fibres, both from the northern and the southern parts of the Empire. The Madras Government has also given directions for the investigation of the fibrous materials procurable in that Presidency, and has issued a Volume of great value. At Bombay a Company has been established for the collection of materials for paper-making, while individuals are paying attention to the preparation of Fibres. In Sindh and in the Punjab, the culture of Flax has been taken up and patronised by the Indian Government and the Court of Directors—*Dr. Royle in Fibrous Plants.* Only a few years have passed since hemp and flax were almost the sole vegetable fibres used in the manufactures of Great Britain for making cordage &c., but our knowledge of the fibre yielding plants has greatly augmented of late, and numerous Asiatic species may yet be added to the list. Amongst the plants of Eastern and Southern Asia most deserving of attention may be enumerated the following, which are the principal of the fibrous plants there:

Abelmoschus esculentus, ...	Vendee fibre.
Abelmoschus ficulneus, ...	
Abroma augusta, ...	
Abutilon indicum, ...	Tootee.

Abutilon polyandrum	
Abutilon tomentosum	
Acacia leucophlœa	Oody nar.—This tree is common near Cape Comorin. The fibres from the bark are used by the fishermen in making nets. A course kind of cordage is also made from it.
Acacia arabica	Karoovillum nar.
Agave americana	Pitu fibre or great Aloe.
Agave cantala	
Agave discantha	
Agave vivipara	Kathalay.
Agave yuccæfolia	
Ailantus malabaricus	Poroomarum.—Inner bark not much used.
Aletris nervosa	
Aloe indica, or vulgaris	Kuttally nar.
Aloe perfoliata	Aloe fibre
Ananassa sativa	Pine Apple fibre.
Andropogon schœnanthus	Camachy.
Andropogon muricatus	
Arenga saccharifera	
Antiaris saccidora	Arengee.
Areca vestiaria	
Artocarpus, several species	
Bauhinia racemosa	Malfhun.
Bauhinia diphylla	
Bauhinia Vahlii	Yepy tree bark.
Bauhinea tomentosa	Vellay Aatee nar.
Banhinea scandens	
Boehmeria; several species	
Bombax malabaricum	
Borassus flabelliformis	Palmyra fibre.
Bromelia, several species	
Broussonetia papyrifera	
Butea frondosa	
Butea superba	
Callicarpa cana	
Callicarpa lanata	Thondy nar.—Inner Bark. Not much used.
Calotropis gigantea, &c	Ak Mudar or Yercum
Calotropis Hamiltonii	
Calotropis procera	
Cannabis sativa	Hemp
Careya arborea	
Caryota urens	
Chamœrops or Hemp palm	
Chamœrops humilis	
Chamœrops Ritchiana	
Cordia obliqua	Pothooveroosen nar.—Moderate strength
Cocos nucifera	Cocoa.
Corchorus olitorius	Jute.
Corchorus capsularis	
Corchorus fusous	
Corypha, several species	
Crotalaria juncea	Under the name of Canamboo or Wuckoo, it is cultivated extensively in the Southern Travancore districts. It is not exported. Fishing nets are made from them, the best kinds are grown in the Northern district. Sunn (wuckoo nar.)
Crotalaria tenuifolia	
Cyperus textilis	Mat grass, or Coaray.
Cyperus tegetum	
Daphne Bholua	
Daphne Canabinus	
Daphne Gardneri	
Decaschistia crotonifolia	
Dœmia extensa	Ootrum ka bel.
Eriochlœna Candollii	
Eriodendron anfractuosum	
Eriophorum cannabinum	
Eriophorum Commosum	
Erythrina indica	
Ficus religiosa	Arasa nar.
Ficus racemosa	Atti nar.
Ficus indica	Aulamarum nar. Aallen nar.—Not much used.
Ficus oppositifolia	Bodda nar.
Ficus mysorensis	Kul aallum nar.—Not much used.
Fourcroya gigantea	Seemay Kathalay.
Grewia asiatica	Neilgherry nettle.
Gossypium indicum	Indian Cotton.
Gossypium acuminatum	Brazil Cotton.
Gossypium herbaceum	
Grewia asiatica	Beat.
Grewia tiliæfolia	
Grewia rotundifolia	Oonoo—Moderate strength.
Grewia didyma	
Grewia oppositifolia	
Guazuma tomentosa	
Guazuma ulmifolia	

Hibiscus cannabinus	Poolychny fibre.
Hibiscus fragrans	
Hibiscus sabdariffa	Roselle fibre.
Hibiscus striatus	
Hibiscus vesicarius	Wild ambora.
Hibiscus rosa chinensis	Shoe plant fibre.
Hibiscus vitifolia	
Hibiscus lampas	
Hibiscus macrophyllus	
Hibiscus manihot	
Isora corylifolia	Valumbrikai, Kywen nar.—This is the most valuable fibre in Travancore. The plant grows abundantly at the base of the hills. It is from the stem of this shrub that the natives produce fibre.
Juncus	
Lodoicea Seychellarum	
Linum usitatissimum	Flax
Maranta dichotoma	
Marsdenia Roylei	
Marsdenia tenacissima	
Mimosa Intsia	Eenjy nar.
Musa paradisiaca	Plantain fibre.
Musa sapientum	
Musa textilis	
Pandanus	
Pandanus odoratissimus	Fragrant Screw Pine.
Papyrus	
Pangres	
Paritium macrophyllum	
Paritium tiliaceum	
Raphis cochinchinensis	
Raphis flabelliformis	
Raphis	
Saccharum sara	Sara.
Saccharum munja	
Sanseviera zeylanica	Moorghee, or Marool.
Salmalia malabarica	Elavum parooty.
Sesbania aculeata	
Sesbania cannabina	
Sida asiatica	
Sida gravcolens	
Sida indica	
Sida rhomboidea	
Sida rhombifolia	
Sida tiliæfolia	
Sida periplocifolia	
Sida populifolia	Used for Cordage &c.
Strychnos potatorum	Katha vennaer.
Smilax ovalifolia	Krinkoddy nar.—Used for tying bundles &c.
Sterculia guttata	
Sterculia ornata	
Sterculia villosa	
Terminalia alata	Mooroothen nar.—Bark, very strong and lasts many years used for dragging timber, cordage &c. Common in the forests
Terminalia belerica	Umburathee nar.
Triumfetta lobata	Koorinja.
Tylophora asthmatica	
Typha elephantina	
Urena lobata	Bun—Ochra.
Urena sinuata	
Urtica, several species	
Vernonia anthelmintica	Coat seeragum.
Yucca angustifolia	
Yucca gloriosa	Pita or Adam's Needle.
Yucca aloifolia	

In the Tenasserim Provinces, as in other parts of India, cordage is made of coir, the outside shell of the cocoa-nut, but ropes are more frequently made from the bark of three different trees belonging to the genera hibiscus, paritium, and sterculia.—viz. Paritium macrophyllum and P. tiliaceum; Hibiscus macrophyllus, Sterculia guttata and Sterculia ornata.—*Mason*. Of the very extensive and varied fibrous substances in all parts of the Madras Presidency only a few are cultivated as articles of commerce, though Southern India is abundantly supplied with fibrous materials for every description of textile manufacture, from the coarsest packing cloth, to the finest cambric, lawn, or muslin. It would be impossible to say how far the cultivation of fibrous

plants might be carried, and what would be the demand for them in the Madras Presidency, if properly prepared for the market; but there is no doubt, that the usual careless and slovenly mode of preparing these materials, has hitherto tended greatly to interfere with their sale in the European market. A large and interesting class of Fibrous substances, which have hitherto attracted but little attention, is the Barks of Trees, many of which yield a strong and ready substitute for rope, and from the quantity of Tannin, which some of them contain, they resist moisture, and retain their strength for a long time. With a little care and the employment of simple machinery, excellent ropes, mats and baskets might be prepared from some of these substances, and they would probably find a ready sale for agricultural and commercial purposes. One of the most common of these barks is the *Bauhinia diphylla*, called Authee nar, Yepy, and Apa. This is a strong coarse brown bark of which the Natives make temporary ropes for securing thatch, matting or fences. The barks of several other Bauhinias are used for the same purposes The Ara nar is the bark of the Bauhinia parvifolia, of which matches for native guns are made. This class also includes the barks of the Banian, Ficus indica or Ala nar, Peepul, Ficus religiosa or Arasa nar, Ficus racemosa, Atti nar, Ficus oppositifolia, Bodda nar, Ficus (?) Cullethy nar. the bark of the Ficus tomentosa, the barks of several species of Acacia, as the Babool (*Acacia arabica,*) or karoovalum nar, the white Acacia, or Oday nar, (Acacia Leucophlea,) Velvaila nar, Wrightia tinctoria, and a number of other plants not yet identified. The trailing roots, twigs, tendrils, and drops of a number of plants are used for the same purposes.—*M. E. J. R.* 1855.

In *China* Mr. Fortune says that the staple summer crops are those which yield textile fibres. The plant well known by the name of jute in India, a species of Corchorus—which has been largely exported to Europe of late years from India, is grown here to a very large extent. In China this fibre is used in the manufacture of sacks and bags for holding rice and other grains. A gigantic species of hemp (Cannabis) growing from ten to fifteen feet in height is also a staple summer crop. This is chiefly used in making ropes and string of various sizes; such articles being in great demand for tracking the boats up rivers and in the canals of the country. Every one has heard of China grass-cloth—that beautiful fabric made in the Canton province and largely exported to Europe and America. The plant which is supposed to produce this (Urtica nivea) is also abundantly grown in the western part of this province and in the adjoining province of Kiangse. Fabrics of various degrees of fineness are made from this fibre and sold in these provinces, but none so fine as that made about Canton; it is also spun into thread for sewing purposes, and is found to be very strong and durable. There are two very distinct varieties of this plant common in Chekiang—one the cultivated, the other the wild. The cultivated variety has larger leaves than the other; on the upper side they are of a lighter green, and on the under they are much more downy. The stems also are lighter in colour, and the whole plant has a silky feel about it which the wild one wants. The wild variety grows plentifully on sloping banks, on city walls, and other old and ruinous buildings. It is not prized by the natives, who say its fibre is not so fine, and more broken and confused in its structure than the other kind. The cultivated kind yields three crops a year. The last great crop which I observed was that of a species of juncus, the stems of which are woven into beautiful mats, used by the natives for sleeping upon, for covering the floors of rooms, and for many other useful purposes. This is cultivated in water, somewhat like the rice-plant, and is therefore always planted in the lowest part of these valleys. At the time of my visit, in the beginning of July, the harvest of this crop had just commenced, and hundreds of the natives were busily employed in drying it. The river's banks, uncultivated land, the dry gravelly bed of the river, and every other available spot was taken up with this operation. At grey dawn of morning the sheaves or bundles were taken out of temporary sheds, erected for the purpose of keeping off the rain and dew, and shaken thinly over the surface of the ground. In the afternoon before the sun had sunk very low in the horizon it was gathered up again into sheaves, and placed under cover for the night. A watch was then set in each of the sheds; for however quiet and harmless the people in these parts are, there is no lack of thieves, who are very honest if they have no opportunity to steal. And so the process of winnowing went on day by day until the whole of the moisture was dried out of the reeds. They were then bound up firmly in round bundles, and either sold in the markets of the country, or taken to Ningpo and other towns where the manufacture of mats is carried on on a large scale. —*Fortune.* Hemp is cultivated in the provinces north of the Meiling, but the plant also grows in Fuhkien; the grasscloth made from it is not so much used for common dresses as cotton and silk. There are three plants which produce a fibre made into cloth known under this name, viz., the *Cannabis sativa* or hemp at Canton, the *Urtica nivea*, a species of nettle grown about Sucham, and the *Sida tiliæfolia* near Tientsinfu. —*Williams' Middle Kingdom, page* 108. Fibres of various kinds are largely imported into England, the quantity of foreign Flax and Hemp in three years having been as follows:—

	Flax Tons.	Hemp Tons.	Total Tons.
1851	59,709	64,671	124,380
1852	70,129	53,714	123,843
1853	95,169	63,142	158,311

The money value of the above was calculated at Rupees 2,72,04,700. When plants are grown to produce fibres, they ought to be sown thick, to induce them to grow tall and slender, and without branches, so that the straight stems may yield a greater length of fibre, and it may be laid down as a general rule that the softness or clearness of a fibre, forms a good criterion of its strength and vice versa. The best process to be followed in extracting the fibres of plants, is of importance to be known. It will have been seen that the method of cleaning fibres by rotting is not suited to warm-climates owing to the rapidity with which putrefaction sets in, and to the irregular periods at which the fermentive action commences, in different parts of the plant. While one part of a heap of leaves or stalks are beginning to ferment other parts are brown and stained with putridity, the central parts remaining fresh and unaltered. As a general rule, every days steeping of a fibre, takes from its strength, and imparts more or less color. Therefore, with plants having bark and woody fibres, of which much of the cordage of commerce is made,—the fibre can be purest extracted, by beating them, at first, well with a wooden mallet in order to loosen and allow the removal of the bark from the stalk, as it is generally on the inner surface of the bark that the fibres suitable for cordage usually occur. When the bark has been brought into a pulpy state, it should be well washed in clean water, to remove as much of the sap as possible, as this is the part, in which the putrifactive process first begins. The leaves, stalks, or barks of plants should be cut when in full vigour and in their bright green colour; when old, dried or decayed, they yield coarse and stiff fibre. Only so much should be cut at a time as can be cleaned within two days, and the plants when cut should not be exposed to the sun, as the sap dries up, and the process of cleaning them is made more tedious. The sooner the sap, pulp, and impurities can be removed from the fibre, the cleaner and stronger will it be. The process of rotting or steeping the fibres is objectionable in a warm climate, and is now being abandoned even in cold climates, as it discolors the fibres and takes from their strength. If a plant be well crushed or beaten soon after it is cut, it may be immersed in water, for a night, and a good deal of the injurious part of the sap will be removed. Beating, crushing, and scraping fibres, improves their quality, and the more a fresh fibre gets knocked about, provided it be not cut across or rendered too short in the staple, the softer and more pliant does it become. These remarks are particularly applicable to the coir fibre. All that is necessary with the Agave, Yucca, Fourcroya and Sanseviera is to beat or crush the pulp with a mallet, or crushing cylinder, or a brake, and then to scrape away the pulp and wash the fibres. In cleaning the fibres of pulpy

FIBRES AND FIBROUS PLANTS.

plants, the plants should first be bruised or crushed, and the juice which exudes may be kept to be converted into a coarse kind of vinegar required in another process. For this part of the process the common sugar mill of India, with two perpendicular rollers and a channel to convey the juice into some convenient vessel, answers well, and the cost does not exceed ten Rupees. Where this small sum cannot be afforded, and labour is abundant, the plant may be well beaten with wooden mallets, on planks, until all the pulp is loosened. When it has assumed a pulpy consistence, the plant should be seized at both ends and well twisted on itself in various directions, to squeeze out the sap. It should then be well washed in plenty of water, untwisted, and scraped on a board, in small handfuls at a time, with a blunt straight knife, on a long piece of hoop iron, fastened into a wooden handle. When all impurities are thus removed the fibres may be soaked for an hour or two in clean water and then hung up in the shade to dry, the latter being a point of much importance as exposure to the sun at first, is apt to discolor them. By this simple process, fibres, of great length, of a silky appearance and of a good colour, can readily be prepared. The scrapings must be well washed and set aside in the shade to dry as tow, for packing, or as a material, for making paper. This process is applicable to all fleshy or pulpy plants such as those known as Aloe plants, the Agave, and Yucca, Sanseviera and plantain. Prices have been offered in England, of Rs. 250 to Rs. 700. £25 to £75, for fibres cleaned in this manner, while only from £10 to £18 per ton was offered for fibres sent to England at the same time, but which had been cleaned by the ordinary rotting process.—*Dr. Hunter.*

Comparative strength of fibres. Hemp, Russian.—The difference in strength between the best and ordinary Russian Hemp is in the proportion of 5 to 4 and sometimes 6 to 4, and the strength of the best Russian Hemp to the best Sunn bears a proportion of 6 to 4.—*Royle, Fibrous plants, p.* 277. The Strength of fibres is of very great consequence. Dr. Royle remarks, (*Fibrous Plants*) that having lately had occasion to report on some Indian fibres, he was anxious to ascertain the comparative strength of several of those fibres, which were, upon the whole, but little known. He therefore had equal weights and equal lengths of several of these fibres taken, their ends tied and fixed in a vice, and then the number of pounds ascertained with which each broke. In these experiments,

Petersburgh clean Hemp, ...	broke with	160 lb.
A fibre from Travancore, called Wunkoo, ...	„	175
Yercum fibre, ...	„	190
Jubbulpore Hemp, ...	„	190

China grass, from China,... with 250 lb.
Rheea fibre or China grass, from Assam,... ... ... } " 320
Wild Rheea, also from Assam, " 343
Hemp from Kote Kangra, in the Himalayas, bore 400 lb. without breaking.

Rheea.—Dr. Roxburgh found the Rami or Calooe bore 240 lb. when Hemp bore 158 lb. and Sunn 150 lb., Messrs. Sharpe, in 1815, found a cord bore 252 lb., when Russian Hemp was only required to bear 82 lb., So in Dr. Royle's experiments with these fibres in an untwisted state, Petersburgh Hemp bore only 160 lb. when China-grass bore 250 lb., the Rheea 320 lb. and the Wild Rheea 343 lb., Mr. Henly had previously found the Kunkhoora or Rheea to bear about three times the weight of Russian Hemp.—*Royle's Fibrous Plants, p.* 372. In the year 1810 three bales of this Calooe fibre were sent to the India House, having been produced in the Botanic Garden at Calcutta. In December 1811, one of these bales was sent to Messrs. Sharpe, then of Mark Lane. On the 4th February 1812, they reported, that having brought the Calooe fibre to the state of Hemp for the use of cordage, a thread was spun, of the size of those spun in the King's Rope yards, which bore 252 lb., whereas the weight required to be borne in his Majesty's yards by Russian Hemp of the same size is only 28 lb.—*Royle's Fibrous Plants, p.* 347. Experiments on strength of Rope made from samples of Fibre of the growth of India, received from Dr. Royle, at Messrs Huddart's Rope manufactory, Limehouse, February 13, 1854.

Description and Name.	Size of Rope.	Number of Yarns in the strand. Length of Yarn in Rope.	Strength of Rope in lbs.	Strength of Rope per Inch, circumference squared.	Size of Rope at breaking.	Tar absorbed.	Amount of stretching.
	In.						
Wild Rheea, 1st experiment,	4¼	44	132	19,032	·814	4¼	1-7th	1 in 16
Do. 2d do.	4¼	44	132	21,025	·894	4¼	1-7th	1 in 16
Rheea Fibre, ..	4¼	44	132	20,486	·910	4¼	1-9th	1 in 16

It will be seen from the abstract, that amongst the thirteen samples of the 2 inch rope, the Deyrah Hemp stands the fifth in strength and the twelfth in elasticity. ('Journ. Agri-Hortic. Soc.' iii. p. 227.) Further details are given in other tables, at pp. 224-25 of the Journal. But Hemp of far greater strength is produced in these, which are probably the native hills of the plant. Mr. Williams, of Jubbulpore, gave to Dr. Royle in the year 1853, a sample of Hemp, which he stated had been forwarded to him by D. F. Macleod, Esq. as the produce of Kote Kangra, in the Sikh Himalayas. This Dr. Royle has, in his Lecture and Experiments as well as in communications with various individuals, called Kote Kangra Hemp. It is the fibre which is mentioned (at p. 133) as not breaking with a weight of 400 lb., when China-grass from Assam broke with 320 lb., and Petersburgh Hemp with only 160 lb. It has moreover, appeared to all the practical men who have since then examined it, as the strongest fibre with which they were acquainted.—*Royle's Fibrous Plants, p.* 331.

Abstract of Report of Proof of Moorgahvi, Arracan, Deyra, and Jetee Rope, compared with Europe, Manilla, New Zealand, Sunn, and Coir Rope, in the order of Strength and Elasticity.

No. of Sample.	STRENGTH. 2-Inch Rope. NAMES.	Weight at which broken.	STRENGTH. 1¾-Inch Rope. NAMES.	Weight at which broken.	ELASTICITY. 2-Inch Rope. NAMES.	Length stretched before breaking.	ELASTICITY. 1¾-Inch Rope. NAMES.	Length stretched before breaking.

From Royle's Fibrous Plants, page 269.

(3592) FICOIDEÆ. Drs. Royle and Ainslie mention no medicinal species in this order, but allude to the genus *Mesembryanthemum*, as a ready source of soda. Dr. Roxb. speaks of the order as of little consequence in a medicinal view; he mentions that all the species are rich in alkaline carbonates; but this is sufficiently explained by their usually frequenting the sea shore.—*O'Shaughnessy, page* 354.

(3593) FICUS, a large genus of Plants belonging to the natural order *Urticaceæ*, having the flowers, both males and females, mixed indiscriminately on the inside of a fleshy receptacle, which is so concave that its edges are drawn to-

gether into a narrow opening. This is illustrated by the common eatable Fig, the receptacle of *Ficus Carica*, which, although resembling a fruit as simple as a gooseberry, is in fact a collection of a large number of minute unisexual flowers growing to a succulent base; as its apex will be found the narrow opening where the edges of the receptacle are drawn together, and when its interior is laid bare the flowers are seen closely packed all over its surface, divided from each other by soft colourless bristle-like bracts or scales. What are called the seeds in the ripe fig are the pericarps, each of which contains a single seed. The calyx is variable in the number of its segments, sometimes having only 3, sometimes 7 or 8. The stamens are solitary in many species, 3 in others, and 5 in some. The pistil consists of a single ovary terminated by an awl-shaped style, ending in a 2-lobed stigma. The number of species of *Ficus* is very considerable, perhaps as great as that of any arborescent genus. They are all either tropical or inhabitants of warm countries. Some are small plants creeping upon the surface of rocks and walls, or clinging to the trunks of trees like ivy; others are among the largest trees of the forest. All travellers in the woods of South America speak of the noble aspect of the fig-trees (meaning species of *Ficus* not of the cultivated sort), of their gigantic dimensions, and of the thick delightful shade cast by their leafy heads. They are specially remarkable for throwing out roots from their branches, which, after they have reached the ground and established themselves there, increase rapidly in diameter, produce other branches, and thus contribute to extend an individual over a considerable space of ground. Frazer speaks thus of what he saw of their habits in the forests at Moreton Bay in Australia:—"I observed several species of *Ficus* upwards of 150 feet high, enclosing immense iron-bark trees, on which originally the seeds of these fig-trees had been deposited by birds. Here they had immediately vegetated, and thrown out their parastical and rapacious roots, which adhering close to the bark of the iron-tree had followed the course of its stem downwards to the earth, where, once arrived, their progress of growth is truly astonishing. The roots of the *Ficus* then increase rapidly in number, envelope the Iron-bark, and send out at the same time such gigantic branches that it is not unusual to see the original tree, at a height of 70 or 80 feet, peeping through the fig, as if itself were the parasite on the real intruder. In the singular angles or walls, as they are here termed, which are formed by the roots of these trees, and of which I observed many 16 feet high, there is room enough to dine half a dozen persons. The fruit is eagerly sought by Regent Birds (*Sericulus chrysocephalus*), blue pigeons, and Swamp Pheasants (*Cuculus Phasianus*), and the spreading and massy boughs support a number of superb parasitical plants." Reinwardt assures us ('Ueber den Charakter der Vegetation auf den Inseln des Indischen Archipels') that he observed on the island of Semao a large wood whose trunks all proceeded from one single stem of a *F. Benjamina*, all united with each other by their branches though the trunks were distinct. The well-known *F. Indica*, or Banyan-Tree, is another instance of this peculiar habit. The species abound in a milky juice containing caoutchouc, and there is every reason to believe that what of this substance comes from Java is exclusively procured by tapping different species of *Ficus*. The best known on the continent of India is yielded by *F. elastica*. Although the fruit of *F. Carica* and some others is eatable, yet the whole genus abounds in an acrid highly dangerous principle, diffused among the milky secretion. This is perceptible even in the common fig, whose milk produces a burning sensation on the tongue and throat; but when the fruit of that species is ripe, the acridity is destroyed by the chemical elements entering into new combinations. In some species it is so concentrated that they are among the most virulent of poisons. *F. toxicaria*, a Sumatra species, and *F. dæmona*, from Tanjore, derive their names from this circumstance, in which many more equally participate.—*Eng. Cyc.* Wight in Icones gives,

elastica,		

The genus *Ficus* is celebrated for one of the species yielding the Fig, one of the most early cultivated of fruits, and another yields the Caoutchouc of Assam, while the Bur and the Peepul are, in India, two of the most highly esteemed of trees. It is a genus numerous in species which abound in all parts of India. It is probable that the bark of some of the species, like that of the Mulberry, may be converted into half-stuff, as Mr. Ostandje states that the bark of one of the species is used for paper making in the Island of Ceylon.—*Royle, Fib. Plants*, p. 348.

(3594) FICUS AMPELOS.

Barenki, Tel.

A large tree, a native of mountainous countries chiefly. Trunk remarkably short, but very thick

and sometimes so completely ornamented with small very leafy branchlets, as to hide it entirely. The leaves are used to polish ivory, horn &c., The leaves of the Trophis aspera also called Warinka are used for the same purpose.—*Roxb. M.S.S.*

(3595) FICUS BENJAMINOIDES. Tenasserim Banyan. Few persons are aware that a species of ficus exists in the Tenasserim Provinces which has the habit of dropping roots from its branches that root in the ground, and become trunks as large as the parent tree, to an extent nearly equal to the famous banyan. It escapes notice because it developes itself in the greatest perfection near the mangrove swamps, and some who see it call it a mangrove; and it never grows spontaneously except on the banks of tide water streams. It is not found however, in the mangrove lands which are under water every tide, but above that belt where Heritiera trees, and their associates show themselves, on land that is inundated by the spring tides only. Specimens are seen farther toward the interior, as on the banks of the Gyaine, but on the low banks near the sea between Tavoy and Mergui, the trees often form labyrinths from which Mr. Mason, more than once has found it difficult to extricate himself. It is rather remarkable that the tree has never been introduced into the towns, where it would be quite an ornament to the sides of the public walks. In a few instances he has seen the tree planted on high ground, one at a village near the sea-coast west of Tavoy, where it appears to grow very well. A very nearly allied species, Wight says, is "much used as an avenue tree" in southern India. Perhaps our tree will be referred to the same species. *F. Benjamina;* but though much resembling it, there is still a difference that appears to be constant, and therefore specific. The *Benjamina* has the fruit smooth on short stems, while the Tenasserim tree has rough fruit and stemless. There is a difference too in the leaves, but it is only slight, and not alone sufficient to establish a species. Wight, in uniting *F. nitida* with *F. Benjamina*, characterizes the united species thus: "*Ficus Benjamina*, Leaves oval and obovate, obtuse, polished; fruit axilliary, paired, smooth." The Tenasserim tree may be thus characterized: *Ficus Benjaminoides*. Leaves oval, suddenly acuminate, smooth, polished above; fruit axilliary, paired, sessile, rough.—*Mason.*

(3596) FICUS CARICA. Linn. The common Fig. *Diœcia Triandria*, Linn. The fig has been employed in diet and in medicine from very early times. A small tree. Leaves cordate often palmately lobed, scabrous above, pubescent beneath. Flowers monœcious, numerous, stalked, and inclosed within a pear-shaped fleshy receptacle, which converges so as to leave only a small orifice at the apex, forming what is commonly called the fruit or Fig, with a few bracteal scales at its base. *Male.* Perianth 3-lobed. Stamens 3. *Female.* Perianth 5-parted. Ovary semi-adnate. Style single. Stigmas 2. Utricle single, covered with the persistent, somewhat fleshy, perianth, and sunk into the fleshy receptacle. Achænium lenticular, hard. Embryo curved, within fleshy albumen.—Native of Asia, long introduced into Europe. Nees von E. 97. St. and Ch. 154. Formerly, as in the present day, the process of caprification was practised, to assist the ripening of the fruit. This consists in puncturing the fruit with a sharp instrument covered with oil. The trunk and branches of the common as of other Fig trees abound in milky, usually acrid juice. This is found also in unripe Figs; but as they ripen, mucilaginous and saccharine matter is produced, the fig becomes soft, juicy, and of a delicate flavour in all favourable climates. When nearly ripe, they are dried in large quantities in the south of Europe, and are exported to this country. They form also an article of commerce in Asia, imported into India from Affghanistan and Persia.—*Royle.* In the Dekhan, this tree bears fruit almost the whole year round. There are two varieties, the white and the blue, cultivated in all the native gardens, the young trees producing the finest fruit. The Italians, as the fruit begins to ripen, prick each with a pin, putting a drop of sweet oil on the spot;—it is said that this causes an increase in the size of the fruit. The trees may be grown by layers and suckers at the commencement of the rains, and during the cold season. Cuttings strike easily in the course of six weeks. The finest fruit that Dr. Riddell has seen grown has been on young trees of two years old, near which dead animal matter had been buried. The trees should be pruned annually, and the best way is to cut down the old branches that have borne fruit, leaving one or two buds that promise to throw out healthy shoots. The fruit when ripening must be protected from birds, either by nets or bags.—*Riddell.* In Tenasserim though a stunted fig-tree or two may be seen in a few European gardens, the fruit rarely comes to perfection; although there are perhaps more indigenous trees in the jungles belonging to the fig genus, than to any other in the whole vegetable kingdom.—*Mason.*

(3597) FICUS CORDIFOLIA. Heart-leaved Fig. In Tenasserim this is the tree which usually supplies the place of the peepul in the public places, and in the neighborhood of religious edifices. "It approaches," says Roxburgh, "nearest to *F. religiosa*, of any species I know, yet it is easily distinguished from it by the leaves being narrower in proportion to the length, with much shorter points, and instead of the lobes forming a sinus at the base there is a small degree of projection at the insertion of the petiole. And in the second place by the fruit being perfectly round and not, as in *religiosa*, vertically compressed."—*Mason.*

(3598) FICUS ELASTICA, the Indian Caoutchouc-Tree, is now a common tree in the hothouses of Britain. It has large, shining, oval, pointed, thick leaves, small axillary eatable fruits, the size of an olive, and long pink or red terminal buds, composed of the stipules rolled together. This species inhabits the Pundua and the Juntipoor Mountains, which bound the province of Silhet on the north, where it grows to the size of a European sycamore, and is called Kastneer. It is chiefly found in the chasms of rocks and over the declivities of mountains among decomposed rocks and vegetable matter. It produces when wounded a great abundance of milk, which yields about one-third of its weight of caoutchouc. It grows with great rapidity; a tree is described as being 25 feet high, with the trunk a foot in diameter when only four years old. The juice of this valuable plant is used by the natives of Silhet to smear over the inside of baskets constructed of split rattan, which are thus rendered water-tight. Old trees yield a richer juice than young ones. The milk is extracted by incisions made across the bark down to the wood, at a distance of about a foot from each other, all round the trunk or branch up to the top of the tree, and the higher the more abundant is the fluid said to be. After one operation the tree requires a fortnight's rest, when it may be again repeated. When the juice is exposed to the air it separates spontaneously into a firm elastic substance, and a fetid whey coloured liquid. Fifty ounces of pure milky juice taken from the trees in August yielded exactly 15½ ounces of clean-washed caoutchouc. This substance is of the finest quality, and may be obtained in large quantities. It is perfectly soluble in the essential oil of Cajeput. (Roxb., 'Fl. Ind.,' iii. 545.)—*Eng. Cyc.* This India-rubber tree, (*Ficus elastica*) abounds in Assam, but the outer Himalaya at Punbabarree, is its western limit. It penetrates amongst the mountains, as far as the Teesta valley in Sikkim but is of small size.—*Hooker. Him. Jour. Vol.* I. *page* 102, *and* II. *p.* 13.

(3599) FICUS GLOMERATA.

Glomerous fig tree, ENG.	Attee marum, TAM.
Medee, TEL.	Rulla kith mara, CAN.
Gol seer, HIN.	Oombur, DUK.

A large tree with fruit like the common fig, grows in clusters along the branches, flavour insipid, but eaten by the poorer classes. This tree thrives best near a watercourse, or on the banks of rivers.—*Riddell.*

(3600) FICUS INDICA.

Banyan tree, ENG.	Bur ka jhar, HIN.
Ala marum, TAM.	Vata vriksha, SANS.
Ahlada mara, CAN.	Mari chettoo, TEL.

Ficus Indica, the Banyan-Tree, is a native of most parts of India, both on the islands and the mainland. Roxburgh states that it is found in its greatest perfection and beauty about the villages on the skirts of the Circar Mountains. The leaves are ovate, heart-shaped, 3-ribbed, and entire; when young, downy on both sides; when old, much smoother: they are from 5 to 6 inches long, and from 3 to 4 inches broad; at the top of the leafstalk on the under side is a broad, smooth, greasy-looking gland. The figs when ripe grow in pairs from the axils of the leaves, are downy, and about the size and colour of a middle-sized red cherry. The wood is light, white, porous, and of no value. The Brahmins use the leaves, pinned together as plates, to eat off; bird-lime is manufactured from the tenacious milky juice. If the seeds drop in the axils of the leaves of the Palmyra-Tree (*Borassus flabelliformis*), the roots grow downwards, embracing the trunk in their descent; by degrees they envelop every part except the top, whence in very old specimens the leaves and head of the Planyra are seen emerging from the trunk of the Banyan-Tree, as if they grew from it. The Hindoos regard such cases with reverence, and call them a holy marriage instituted by Providence. The Banyan-Tree, covering, with its trunks a sufficient space to shelter a regiment of cavalry, and used as a natural canopy for great public meetings, has been so often described by writers on India as to have become familiar to the reader. The branches spread to a great extent, dropping their roots here and there, which as soon as they reach the ground rapidly increase in size till they become as large as and similar to the parent trunk, by which means the quantity of ground they cover is almost incredible. Roxburgh says that he has seen such trees full 500 yards round the circumference of the branches, and 100 feet high, the principal trunk being more than 25 feet to the branches, and 8 or 9 feet in diameter. Gum lac is obtained from this tree in abundance. The white glutinous juice is applied to the mouth to relieve tooth-ache; it is also considered a valuable application to the soles of the feet when cracked and inflamed. The bark is supposed to be a powerful tonic by the Hindoos. An excellent account of such a tree will be found in the 'Oriental Annual' for 1834; and a graphic description of the mode of growth in Rumf.'s 'Herbarium Amboinense,' vol. iii. p. 126. See also 'Asiatic Researches,' vol. v. p. 310. It is called Vuta in Sanscrit, Bur or But in Bengali, Bagha in Cingalese, a glutinous juice is extracted by incision, from which bird-lime is prepared.—*Riddell.* The drops when well prepared by water seasoning, oiling &c. are valued for tent poles, spars of small vessels &c. The timber of the tree does not seem to be employed, but Mr. Rohde has used planks, sawn from large drops after they had been seasoned in water with advantage: for knife boards it is excellent. Bird-lime is pre-

par ed from the tenacious milky juice. The leaves are sewn together for plates to eat off.—*Rohde M.S.S.* Dr. O'Shaughnessy, states that the lac insect abounds on it, and the bark yields abundance of milky juice containing caoutchouc. —*O'Shaughnessy.*

(3601) FICUS INFECTORIA. The waved leaved fig tree.

Joovee, TEL.	Kallalin, TAM.
Jovee, HIND.	Bassari mara, CAN.

(3602) FICUS NITIDA, the Chinese banyan, is one of the most valuable trees for ornamental purposes met with in the south of China. It grows rapidly with but little care, its foliage is of a glossy green colour, and it soon affords an agreeable shade from the fierce rays of the sun, which renders it peculiarly valuable in a place like Hong-kong.—*Fortune's Tea Districts, page* 6. A fig-tree (*Ficus nitida*)—a kind of Banyan—is a great favourite with the priests, and is always found growing beside the temples, to which its dark green leaves and wide spreading branches afford an agreeable *shade* from the fierce rays of the sun.—*Fortune's Wanderings, page* 381.

(3603) FICUS RACEMOSA. COUNTRY-FIG. Linn.

Attie pullum, TAM.	Bodda wood, ENG.
Guller, DUK.	Boddah kurra, TEL.
Oodumburra, SANS.	

A large tree common throughout the country, the milky juice of this tree is considered a valuable external application in ring-worm.—*Riddell.* Attai-kai, *Tam.* Madipundoo, *Tel.* the fruit is used in various ways, dried, in curries, roasted and eaten, pickles are likewise made with them. —*Jaffrey.* This species of fig is of an inferior quality and is only eaten by the poor.—*Ainslie, page* 222.

(3604) FICUS RELIGIOSA. Poplar leaved fig tree.

Ray amun, TEL.	Bogaba, CYNG.

F. religiosa, the Pepul-tree, is a large tree, common in every part of India, especially near houses, where it is planted for the sake of its extensive dark grateful shade. It is held in superstitious veneration by the Hindoos, because their deity Vishnoo is fabled to have been born under its branches. The leaves are heart-shaped, long, pointed, wavy at the edge, not unlike those of some poplars; and as the footstalks are long and slender, the leaves actually tremble in the air like those of the Aspen-Tree (*Populus tremula*). Silk-worms prefer the leaves next to those of the Mulberry. The leaves are used for tanning leather by the Arabs, who call the tree Mudah or Vudah, and also Undi. *Zebid.* See 'Asiatic Researches,' iv. 309, for further information concerning this.—*Eng. Cyc.* This very large tree is preferable for avenues to the Banyan, as its shade is not so dense: the wood is not in general use.—*Rohde M.S.S.* It is generally planted about Hindoo temples. The roots are most destructive to buildings, for if once they establish themselves amongst the crevices, there is no getting rid of them.—*Riddell.* Pepul bark is deemed a good tonic; the lac insect also flourishes on this tree.—*O'Shaughnessy.* In Tenasserim, the F. religiosa, or aspen-leaved peepul, is quite an ornamental tree but very scarce. The peepul of the residents, but not of the Burmese who recognize the distinction, is an allied but different species of ficus. It is the most sacred of trees with the Buddhists, for it was under this tree that Gaudama slept, and dreamed that his bed was the vast earth, and the Himalaya mountains his pillow, while his left arm reached to the eastern ocean, his right to the western ocean, and his feet to the great south sea. This dream he interpreted to mean that he would soon become a Buddha; and it was while seated beneath the same tree, that his dream was verified—He vanquished the forces of Mara, the Indian Cupid, and became divine.—*Mason.*

(3604) FICUS SEPTICA AND F. TOXICARIA have an acrid and corrosive juice; *F. tinctoria* of the Society Isles gives a good yellow dye. The *Ficus elastica* of India (Sylhet and Assam especially) yields abundance of caoutchouc of the best quality. (*See p.* 560.)—*O'Shaughenssy, p.* 577.

(3605) FICUS SYCOMORUS, the Sycomore Fig, is a large tree found in Egypt, where it is planted extensively by the road-side, near villages, and on the sea-coast, for the sake of the shelter of its very widely-spreading branches. The Arabs call it Djummeiz. Forskahl states that its head is often forty yards in diameter. The leaves are broadly ovate, repand or somewhat angular, rather blunt, nearly smooth, heart-shaped at the base. The figs are not produced upon the young branches, but in clustered racemes upon the trunk and the old limbs. They are sweet and delicate, and eaten by the Egyptians. The timber appears to be of little value, for Forskahl excludes it from the lists of carpenters' wood, and places it among the trees which are used for firewood. It can hardly therefore have furnished the wood of which mummy-cases were made, as has been supposed. Professor Don, with greater reason conjectures that they were made from the timber of *Cordia myxa*. When old this tree becomes very gnarled and broken, as is shown in a plate in Salt's 'Abyssinia,' where it is figured under the name of Daroo-Tree, but it is so bare of foliage as to be hardly a picturesque object.—*Eng. Cyc.*

(3605) FICUS TSIELA. Roxb. *Moreæ*, Icon. 668.

Bichie wood, Eng.	Joovi Chetto, Tel.
Bichie maram, Tam.	

I presume, like all the other species of ficus, this is of very little value as timber, the people of Coimbatore know nothing of it.—*Wight.*

(3606) FICUS VIRENS.

Goovee manhoo. Tel.

The Natives use the wood for common purposes. It is well adapted for avenues, being a very ornamental tree constantly in leaf. There are many varieties, the smaller leafed seem to stand better than the banyan in exposed situations.—*Rohde, M.S.S.*

(3607) FIGS.

File, Dan.	Lime It.
Vylen, Dut.	Limas Port.
Lime, Fr.	Pili, Rus.
Feilen, Ger.	Limas, Sp.
Kanus Guz. Hind.	

An instrument of iron or forged steel, cut in little furrows, and used to smooth or give form to metals, wood and other hard substances.—*Faulkner.*

(3610) FILFIL BURREE.—Wild pepper, fruits of Vitex trifolia, agnus-castus and negundo.—*Irvine.*

(3611) FILLIGREE, a style of delicate wire-work, used for ornamenting gold and silver, introduced by the Italians, who call it *filigrana*, a word compounded of *filum* a thread or wire, and *granum* a grain or bead: this is in allusion to the early practice of ornamenting the wire-work with small beads. Wire used for this purpose is seldom drawn round, but flat or angular. The display of filligree work in the Great Exhibition was very wonderful for delicacy of workmanship and fantastic beauty. The chief exhibitors were from Sardinia, Turkey, the Ionian Islands and Malta.—*Tomlinson.*

(3612) FIREWORKS.

Feux de artifice, Fr.	Atishbazee, Guz. Hind.
Fenerwerke, Ger.	Pers.

Well-known devices, composed of explosive combustibles, generally of gunpowder, along with iron, steel, copper, zinc filings, resin, camphor, &c.—*Faulkner.*

(3613) FIREWORKS, in eastern countries form superb displays of pyrotechnic skill. They are of various forms, represent animate and inanimate things, such as trees, tigers, ships, elephants, men, sea-fights, eclipses of the sun and moon. They are imported from China: but are also manufactured in the principal cities of India.

(3614) FISH, (French, Poisson; German, Fisch), a name applied to all the species of a class of animals occupying the lowest station of the four great divisions of the section *Vertebrata*. A fish may be defined as a Vertebrate Animal, breathing through the medium of water by means of branchiæ, or gills, having one auricle and one ventricle to the heart, cold red blood, and extremities formed for swimming.—*Eng. Cyc.*

(3615) FISHERIES OF SOUTHERN AND EASTERN ASIA. The fishermen supplying the markets of Pinang and Singapore are principally natives of China. The fishing boats vary from one to three tons burden; they are of a slight make and calculated to ply at but short distances from the shore. They are pulled by oars and seldom carry sails. The nets are made of twine, tanned with bark of Mangrove. The bamboo fishing-stakes are clumsy contrivances. That they answer well enough in fine weather is more owing to the riches of the sea and their sheltered position, than to the ingenuity of the contrivance or the durability of the materials. In nautical skill, the Chinese fishermen of the Straits settlements are far behind the Malays. The fishmongers are also natives of China, but they form a class far superior to the fishermen. Their trade comprizes the branches,

Fresh Fish,	Shark's Fins,
Dried Fish,	Balachan,
Isinglass (Fish Maws),	Fish Manure, and
Fish Roes,	Tripang.
Red Fish and "Sardines."	

Fresh fish.—The fishermen dispose of their boat loads to the fishmongers who assort the different kinds in heaps, over which sea water is continually poured, and from these the daily customers are supplied. Although comparatively few kinds of Fishes appear on the tables of Europeans, the Malays and Chinese are less nice in their selection, and reject but very few kinds.

Dried fish.—The daily surplus of fishes is cured by the fishmongers. The process commences with a partial abrasion of the scales, after which the larger fishes are opened length-

wise and the intestines removed. Water is repeatedly poured over the fishes till blood and impurities have disappeared, when they are placed in casks in flat layers, between which is thrown a quantity of salt. In this state the fishes remain from 24 to 48 hours, when they are exposed to the sun, and frequently turned, till they are throughly dried. The smaller kinds are not opened nor are they all salted before drying in the sun. The little care bestowed upon the curing appears, however, to be sufficient for local consumption, and none of the settlements in the straits export dried fishes. The pikul of 133⅓ lbs sells from 3 to 7 Spanish Dollars valued at 4s. 6d. The katty being 1⅓ lb, of which 100 go to the picul.

Isinglass, Fish Maws, Fishsounds, or Air-Bladders, (*Paloppong ikan* or *ari ari ikan* of the Malays, *loo-pa* of the Chinese) appear to have formed an article of exportation from the islands of the Indian Archipelago as early as they became visited by the Chinese. When these people commenced to settle in the straits, they not only there collected what are called fishmaws but also from distant localities. Bombay, Ceylow, Madras, Bengal, Tenasserim and most of the Malayan Islands contribute to the annual supply, which is bought up by Chinese dealers at Penang, Malacca, and Singapore. By them the Maws are exported to China. The fact was noted by Mr. Crawfurd, but that the Fish maws are isinglass, appears to have been the discovery of an anonymous correspondent in Parbury's *Oriental Herald* for January 1839. The personal exertions of Mr. McClelland have been mainly instrumental in adding isinglass to the articles of exportation from India to the European Markets. Since 1842, Mr. W. T. Lewis, Assistant Resident Counsellor of Pinang, has made some very successful attempts to inprove the production of isinglass in Prince of Wales Island. But European Merchants there appear unwilling to engage in this novel branch of commerce, as the supply from want of proper care is uncertain, and procurable but in comparatively small quantities. These, however, are no objections to the Chinese dealers, as they are sure of a profitable and quick return of their outlay. The fishes from which isinglass is obtained at Pinang are,

Lates heptadactylus, (*Ikan siyakup.*)
Polynemus indicus, (*Ikan kurow.*)
Otolithus blanritus, (*Ikan salampae.*)
Otolithus ruber, (*Jarang gigi.*)
Otolithus [illegible], (*Jarang gigi.*)
Otolithus [illegible], (*Jarang gigi.*)
Johnius diacanthus, [illegible] (*Tabareh.*)
Lobotes erate, (*Ikan bata*[illegible])
Arius truncatus, (*Ikan saludu,*)
Arius arius, (*Ikan saludu.*)
Arius militaris, (*Ikan saludu.*)

The total Qantities and value of Fish maws imported into and exported from Prince of Wales Island, from 1832 to 1842,

Fish Roes, Red Fish, and *Sardines*. These are condiments and the species used in the preparation, are *Alausa toli*, (*Ikan trubok.*) *Engraulis Broeuii*, (*Bunga ayer or badak.*) *Dussumieria acuta* (*Tamban-bulat*) and *Clupeonia perforata*, (*Tamban-nepes or balub.*)

Shark's Fins.—The Chinese fishmongers of the Straits settlements obtain Shark's fins from the same localities which supply them with Fish maws. These fins are not exclusively selected from Sharks (Squali,) but equally from Rays (Raiæ). Quantities examined at Pinang were composed of Fins of the following Genera: *Stegostoma, Carcharias, Sphyrna, Pristis, Rhinobatus, Tryyon, and Myliobatis.* Of all fishes Sharks and Rays are the most valuable to Chinese. The flesh and entrails of all, not even the electric Rays (*Torpedinidæ*) excepted, are eaten either fresh or dried, the skin is used for polishing or converted into Shagreen; gelatine is obtained from the larger fins, glue from t e smaller. All, except the caudal fins, are cut at the root so as to leave as little flesh as possible. The root is dipped in wetted lime (Chunam) in the erroneous belief of preventing attacks of insects, and then the fins are dried in the sun. Those imported in the Straits Settlements are packed promiscuously in gunny bags, each containing from one half to one Pikul. According to the value in the Chinese market, the fishmongers assort the fins in two kinds, "white" and "black." The *white* consist exclusively of the dorsal fins, which are on both sides of a uniform light colour and reputed to yield more gelatine than the other fins. In China the lovers of gelatinous soups pay from 30 to 40 Spanish Dollars per Pikul of white fins. The pectoral, ventral and anal fins pass under the denomination of *black* fins. The colour, however, varies according to the species from buff to grey or brown, and most of them are of two different colours, the upper surface being dark, the lower light. The black fins, for obvious reasons the most numerous, are supposed to yield a comparatively small quantity of gelatina and sell in China from 15 to 20 Spanish Dollars per Pikul, Mr. W. T. Lewis has communicated the annexed table, shewing the quantity of Shark's fins imported into and exported during 10 years from Penang to China. The total quantities of Shark's Fins imported into and ex-

ported from Prince of Wales Island, from 1832 to 1842.

Balachan.—Is a condiment prepared from small fishes of all descriptions and shell fish. The ingredients are placed in a pit to undergo fermentation, and afterwards dried, pounded and preserved with spices. With the Malays, Siamese, Burmese and Cochin Chinese, Balachan has become a necessary of life, as it serves to season the daily food of these nations.

Fish Manure.—The smallest fishes, and all offal are employed in the spice plantations by the Chinese gardners and agriculturists of Penang, who consider the fluid in which fishes have been salted very useful manure in cocoanut plantations. In addition to the preceding, there are two animal productions of the eastern seas, which also are considered fishes by the Chinese. They are the dried *Holothurioideæ*, called *Tripang Seala* or *Beche de mar*, and *Cuttle Fishes*. Of both, large quantities are annually collected and dried for the market in China. The naked Cephalopods are not only eaten fresh, but one species, a Loligo, forms in its dried state a considerable article of traffic. The preparation consists in removing the inkbag without laying open the mantle. After all impurities have been removed by water, the mollusk is submitted to a slight pressure and ultimately exposed to the sun. Small bundles of one Katty's weight are tied up with slips of ratan, and enclosed in cases holding ten Katties and upwards. The Pikul sells at the rate of 14 to 16 Spanish Dallars.—*Beng. As. Soc. Jour. No.* 208. Along the Asiatic coasts, the high price obtained for the superior and well manufactured Isinglass affords inducements not to be expected elsewhere, but all the parts of Fish, as the Flesh, the Roe, and the Sounds can be turned to account, much of the Fish caught must be everywhere consumed for food, while considerable quantities are dried, and form articles of commerce, as do Shark-fins and Fish-maws. The sounds of many Indian Fishes might, like Sturgeons, yield Isinglass, while Fish-glue and Fish oil might be obtained from others. The natives of Asia are not unacquainted with the modes of preserving fish. The Roe appears among their articles of Materia Medica under the name of Butarookh, and Mr. Crawfurd informs us, that "the Roe of enormous size of a kind of Shad which frequents the great river of Siak in Sumatra, constitutes an article of commerce: while the Balachang of the Eastern Seas, consisting of small fish with prawns and shrimps, first fermented and then dried, gives rise to a considerable traffic, as no food is deemed palatable without it, and its use extends to every country from China to Bengal. In Java and Sumatra a preparation of small fish with red rice, having the appearance of anchovies, and the colour of red cabbage, is esteemed as a delicacy. So in India, the preparation called Tamarind Fish, is much prized as a relish, the acid of the Tamarind being made use of for preserving fish cut in transverse slices: the demand for dried fish exists in every part of Asia, and Isinglass is in request both in Europe and China. It might perhaps become an article of consumption even in India, as it is mentioned in their systems of Materia Medica by the name of ghurree-al-su-mak and sureshum mahee, that is Fish-glue, and is described as a good diet for patients in a decline. The Sele combines the advantages of fineness of flavour, with wholesomeness as food; while considerable in size, it is migratory in habit and enters the Bengal rivers in great shoals in the cold weather. Its swimming bladder is of value as an article of commerce, and its flesh, is esteemed as food in a fresh state; this would become still more valuable if it could be properly cured. In China, the consumption of salted provisions is very general, "and also," in consequence of the immense quantities of both sea and river fish which are daily caught, and the rapidly putrescent nature of that species of provision a considerable portion is cured with salt and dried in the sun, the haut gout which accompanies it being rather a recommendation to the taste of the Chinese. Indeed it is one of their most favorite as well as universal articles of food, and they even overcame their prejudice or indifference for whatever is foreign, on the occasion of salted Cod being introduced for two or three years in English ships, the somewhat decayed condition in which it reached China being said to have been anything but a drawback. This species of cargo, besides its disagreeable nature and the injurious effect which it might have on some delicate articles of shipment, was found during the voyage to breed a peculiar insect, which from the readiness with which it bored into the planks and timbers of a ship, was considered as dangerous, and accordingly the import was greatly discontinued. Sir A. Burnes represents "the mariner of Cutch in the present day as truly, adventurous putting to sea for a trifling reward, and stretching boldly across the ocean to Arabia, the Red Sea, and the Coasts of Zanzuebar in Africa. The Sea vessels of Gurachee sail to Muscat, Bombay, and the Malabar Coast, and the fishing-boats at the mouths of the Indus he describes as good sea-boats, sailing very quickly, and as numerous, because the fisheries there are extensive, and form a source of commerce on the South-Eastern part of the Peninsula of India. In Ceylon as also in China, the Pearl fisheries are of consider-

able value. Dr. Cantor states that at the mouths of the Ganges, the Fishermen have sea-going boats, which they build themselves, and that they are a superior description of Indian sailors, of much more industrious habits than the majority of the natives of India. Still further to the eastward, we see the Burmese and Siamese almost living in boats, and the Malays most formidable as Pirates in the Indian Seas. Mr. Crawfurd represents the Indian Islanders as expert fishermen, and that there is no art which they carry to such perfection as fishing, which the nature of their climate allows them to practise, with hardly any interruption, from one end of the year to the other; the fishing-boats proceeding to sea with the land-breeze at an early hour of the morning, and return with the sea-breeze a little after noon. The fisheries afford a most valuable branch of their commerce, as a great variety of their fish are dried in the sun, or salted and dried, and sent by the inhabitants of the coast in large quantities into the interior Islands, or transmitted to every part of the Archipelago. Dr. Cantor has particularly called attention to the importance of attending to, and encouraging the sea fishery, which is carried on to a very small extent, chiefly because the distance to Calcutta is too great to allow of the carriage of fish in a fresh state. The only class of fishermen who have sea built boats inhabit villages situated near the entrance of the Hoogly. Their chief and most profitable employment consists in attending, with their boats, on the shipping entering and leaving the river for which they receive 16 rupees per diem. Whenever this employment fails, they resort to work with their nets, which they drag during high water along the coasts of the Sunderbuns. Two or three times are generally speaking sufficient to load a boat with fishes and shell-fish (a truly prodigious quantity being brought up in a few hauls). The larger portion of the prize which is not consumed or otherwise disposed of on the spot, is then preserved. This process consists simply in dividing the fish, taking out the viscera, and spreading them in the sun till they become sufficiently dried. The Polynemus Illiah, or Saccolih, enters the mouths of the Ganges in shoals. The Kharrah, or Indian Mackerel, a species of Thynnus, is rather uncommon in this estuary, but it must be found in abundance off the Burmese coast, as from thence, great numbers in a dried state are annually imported into Bengal. The Cartilaginous fishes, Dr. C. states, abound in numbers and species, and are remarkable for their wide geographical distribution. The Sharks enter the rivers to a considerable distance from the sea. Shark skin, he says, is used by the native workmen for polishing wood and ivory; and Shark-fins we have seen are largely exported to China. Of the better known salt water fishes of a wider geographical distribution, such, for instance, as are valued as articles of food, at the three distant points, Calcutta, Madras and Bombay, the market of the first is the least rich in varieties in consequence of its greater distance from the sea. The abundance of the supply, however, makes up for what it wants in variety, and the great demand for fish affords a livelihood to great numbers of fishermen, who every night spread their nets in the river and in the salt-water lake. The Lates nobilis, different species of Polynemus, and the Mugil Corsula daily cover the tables of Europeans, who will more readily recognise these fishes under the names of the Begti or Cockup, Sudjeh, Tupsi (Mango fish), and the Indian Mullet. At the Sandheads, may be found some of those delicious fishes, which are more familiar to the residents of Madras and Bombay; for instance, the Indian Soles, the Roll-fish, and, above all, the Black and White Pomfrets, and the Bummoloh, which latter, in a dried state, is known by the name of the Bombay duck. Of these, the Indian Mullet is the most widely distributed, being common in the Straits of Malacca, the Bay of Bengal, the Persian Gulf, and the Red Sea, also at the Cape of Good Hope. "The bazars in Calcutta," Dr. Cantor remarks, "are always stocked with an ample supply of dry fish, which is consumed partly by the European and native shipping of that port and partly by the poorer classes of Bengal, and the Upper Provinces. Cargoes of this article are annualy imported by the Burmese and Arabs." These dried fishes consist chiefly of the Bummalos, the above named Siluroid Fish, which sells in Calcutta at the rate of four or five rupees a hundred, in Indian Mullet, the Sudjeh, the Begti, and the Kharrah or Indian Mackerel. The demand for dried fish exists all along the coasts of the Peninsula. At Bombay large quantities of the Bummalo, are consumed and exported. At the mouths of the Indus, the fishery is extensive and some Fish Sounds are there procured, perhaps Sounds of Polyneme, but they may also be those of other fish; as the specimens of Fishmaws are very different in form from the Isinglass sent from Bengal. Mr. McCleland, in his paper, calls attention to the very important subject of increasing the supply of fish in the interior of India. Wherever there are any large pieces of water for the purposes of irrigation, as in the Peninsula of India, these he conceives might support quantities of fish, if proper kinds were selected, and pains taken to destroy the injurious animals, in the season when the water is sufficiently low for the purpose. He also suggests that at the different sanitaria which have been established in the mountains, it would be desirable and easily practicable to form rivaria, which would at all times yield a supply of fish. This might, as he suggests, be done by damming up a portion of some of the valleys through which the mountain

streams pass. He also further recommends that the natives of India should turn their attention to the curing of fish in districts where they are abundant, and sending them to others where they are less so, and for consumption at seasons when fresh fish becomes scarce. "The cold season, from November to February, when most fishes are taken, in short. The fishermen not having the means of curing their fish, have nothing to stimulate them to any exertion, beyond what can be consumed when fresh. Had the fisherman the means of preserving the result of his labors, his chief market would commence when the fishing season ends, and his industry would then become a permanent benefit to himself and the county at large. Mr. Crawfurd, after stating that the Fisheries of the Indian islands form the most valuable branch of their commerce, and that a great variety of the fish caught, are dried in the sun, proceeds to observe, that "ordinary dried fish form no portion of the foreign exports of the Indian Islands, but three singular modifications of it do, Fish-maws, Shark-fins, and Tripang, all of which are sent to China in large quantity." The Tripang Swala, or Beche de Mar, often called Sea Slug, one of the tribe of Holothuria, is an unseemly looking molluscous animal, which constitutes, in quantity and value, one of the most considerable articles of the exports of the Indian Islands to China. There are fisheries of Tripang in every Island of the Indian Archipelago, from Sumatra to New Guinea, and upwards of not less than 8,000 cwt. are yearly sent to China from Macassar. The price ranging from 8 Spanish Dollars per picul to 20, and as high as 115, according to the quality. The same author states, that Shark-fins are exported to China from every maritime country, between the Arabian Gulf and the East Indian Islands. A picul of Shark-fins usually sells in China as high as 32 Spanish Dollars, or at £6. 1s. per cwt. which high price makes it evident, that they are only articles of luxury for the use of the rich. In the market of Macassar the ordinary price is about 15 Spanish Dollars, or £2 16s. 8½d. per cwt. Of the three substances mentioned by Mr. Crawfurd as exported from the Indian Islands, one only remains to be noticed, and this is Fish-maws. But of this he merely says that it is a favourite article of the strange luxury of the inhabitants of that country, often bringing as high as 75 Spanish Dollars per picul or £14. 3s. 6d. per cwt. in the market of Canton. Raw dried split fish are abundantly cured (without salt) in Tibet; they are caught in the Yaru and great lakes of Ramchoo, Dobtah, and Yarbru, and are chiefly carp, and allied fish, which attain a large size. It is one of the most remarkable facts in the Zoology of Asia, that no trout or salmon inhabits any of the rivers that débouche into the Indian Ocean (the so-called Himalayan trout is a species of carp). This widely distributed natural order of fish (*Salmonidæ*) is, however, found in the Oxus, and in all the rivers of Central Asia that flow north and west, and the *Salmo orientalis*, M'Clelland, ("Calcutta Journ. Nat. Hist." iii., page 283), was caught by Mr Griffith (Journals, p. 403) in the Banean river (north of the Hindo Koosh) which flows into the Oxus, and whose waters are separated by one narrow mountain ridge from those of the feeders of the Indus. The central Himalayan rivers often rise in Tibet from lakes full of fish, but have none (at least during the rains) in that rapid part of their course from 10,000 to 14,000 feet elevation: below that, fish abound, but I believe invariably of different species from those found at the sources of the same rivers. The nature of the tropical ocean into which all the Himalayan rivers débouche, is no doubt the proximate cause of the absence of *Salmoninæ*. Sir John Richardson (Fishes of China Seas, &c., "in Brit. Ass. Rep. &c.") says that no species of the order has been found in the Chinese or eastern Asiatic seas.—*Hooker Him. Jour.* vol. ii. *page* 183. There are assuredly no seas in the world more abundant in esculent fish than those of the Asiatic Archipelago, and a few of them are of excellent flavour. Fish constitutes the chief animal aliment of all the inhabitants, and everywhere of those of the sea-coast who are by profession fishermen. Among the best fisheries are those of the eastern coast of the Malay Peninsula, those of the entire Straits of Malacca, of the northern coast of Java, and of all the coasts of Borneo and Celebes, with those of the Philippine Islands. The taking of the mother-of-pearl oyster, the pearl-oyster in a few places, of the holothurion or tripang, and of the shell tortoise, form valuable branches of the Malayan fisheries.—*Crawfurd's Dictionary, page* 138. In China, the various modes of catching and rearing fish exhibit the contrivance and skill of the Chinese quite as much as their agricultural operations. According to the Repository, at least one tenth of the population derive their food from the water, and necessity leads them to invent and try many ingenious ways of securing the finny tribes. Nets are woven of hempen thread, and boiled in a solution of gambier, *Uncaria gambier*, to preserve them from rotting. The smacks which swarm along the coast go out in pairs, partly that the crews may afford mutual relief and protection, but chiefly to join in dragging the net fastened to their boats. In the shallows of rivers, rows of heavy boats are driven down, and nets secured to them, which are examined and changed at every tide. Those who attend these nets, moreover, attach scoops or drag-nets to their boats, so loaded that they will sink and gather the sole, ray, and other fish feeding near the bottom. Lifting nets, 20 feet square, are suspended from poles elevated and depressed by a hawser worked by a windlass on

shore; the nets are baited with the whites of eggs spread on the meshes. Cormorants are trained in great numbers in the eastern provinces to capture fish, and are sometimes under such good order that they will disperse at a given signal, and return with their prey without the precaution of a neck-ring. A single boatman can easily oversee twelve or fifteen of these birds, and although hundreds may be out upon the water, each one knows its own master. If one seize a fish too heavy for him alone, another comes to his assistance, and the two carry it aboard. The birds themselves are fed on bean-curd, and eels or fish. They lay eggs when three years old, which are often hatched under barn-yard hens, and the chickens fed with eel's blood and hash. They do not fish during the summer months. The price of a pair varies from $ 5 to $ 8. Mussels are caught in small cylindrical basket traps, attached to a single rope, and floated with the tide near the bottom.—*Williams' Middle Kingd., Vol.* II. *page* 110. The rearing of fish is an important pursuit, and the spawn is sometimes deposited in proper vessels, and placed in favorable positions for hatching. The bulletin Universel for 1239 asserts that in in some part of China, the spawn so taken is carefully placed in an empty egg-shell, and the whole closed: the egg is then replaced in the nest, and after the hen has sat a few days upon it, re-opened, and the spawn placed in vessels of water warmed by the sun, where it soon hatches.—*Williams' Middle Kingdom, p.* 270. Shell-fish and mollusks, both fresh and salt, are abundant in the Chinese market, but they have not been examined scientifically. Oysters of a good quality are common along the coast, and a species of Mactra, or sand calm, is fished up near Macao. The Pearl river affords two are three kinds of freshwater shell-fish, of the genus Mytilus, which are obtained by dredging. The prawns, shrimps, crabs, crawfish, and other kinds of crustacea met with, are not less abundant than palatable, one species of crawfish, as large, but not taking the place of the lobster called lang hai, or dragon crab, cuttle-fish of three or four kinds, and the large king-crab (Polyphemus), are all eaten by the natives, though not relished by others.—*Williams, p.* 272. The true cod has not been observed on the Chinese coast, but several species of Serrani (as Plectropoma susuki, Serranus shihpan, megachir &c.) generally called ship-pan by the natives and garoupa by foreigners, are common about Macao, and considered the most delicate flavoured of any in the markets. Another common and delicious fish is the Polynemus tetradactylus or bynni-carp, usually called salmon by foreigners, isinglass is prepared from its skin. The pomfret, or stang-u of the natives (Stromateus argenteus), is a good pan-fish, but not so delicate as the solefish, many species of which abound in the shallows of the Bogue. Two or three species of mackerel, the Sciœna lucida, an ophicephalus, the mullet, the white rice fish and a kind of shad, complete the list of good table fish found in the markets of Canton.—*Williams' Middle Kingdom, page* 169. Immense quantities of fish are daily caught in the river above the town. Their mode of catching them is ingenious and amusing. One day I was going up a considerable distance in a boat, and set out a little before low water, that I might have the full benefit of the flow of the tide, and get as far up as possible before it turned. On the side of the river, a few miles above Ning-po, I observed some hundreds of small boats anchored, each containing two or three men; and the tide turning just as I passed, the whole fleet was instantly in motion, rowing and sculling up the river with the greatest rapidity. As soon as the men reached a favourable part of the stream they cast out their nets and began to make a loud noise, splashing with their oars and sculls with the intention, I suppose, of driving the fish into the nets. After remaining in this spot for about a quarter of an hour, all the boats set off again, farther up, for the next station, when the crew commenced again in the same noisy manner, and so on for a long way up the river, as long as the tide was flowing; they then returned with the ebb loaded with fishes for the next morning's market. There is another mode of catching fish, which I have frequently seen in the northern provinces, even more curious than that which I have just noticed. Every one acquainted with Chinese history knows that the fish abound in all the rivers and lakes of the north: indeed every little pond swarms with them. I was greatly surprised when I first saw the fish catcher following his profession in these places. He is literally amphibious. He is to be seen perfectly naked, half-walking, half-swimming; now he raises his arms and hands above his head, and, bringing them down, strikes a sharp blow upon the water, making a loud and splashing noise. His feet are not idle; they warn him that a fish is at hand, and they are now feeling for him amongst the mud at the bottom of the pond. The next moment the fisherman has disappeared: he is now under water, and he remains so long that you think something has happened to him. There is, however, no cause of fear: a few seconds more and he appears, rubbing his face and eyes with one hand, and in the other triumphantly holding up the poor little fish which he has just captured. It is immediately placed safely in his basket, and the work goes on as before. The surface of the water is struck and splashed, as I have just described, in order to freighten the fish which are swimming amongst the feet of the Chinamen. Being freightened, they dive immediately to the bottom amongst the mud, where they are felt by the feet, and are soon taken by these expert divers. But the most singular of all the methods of catching fish in China is that of training and employing a large

species of cormorant for this purpose, generally called the fishing cormorant. These are certainly wonderful birds. I have frequently met with them on the canals and lakes in the interior, and, had I not seen with my own eyes their extraordinary docility, I should have had great difficulty in bringing my mind to believe what authors have said about them. The first time I saw them was on a canal a few miles from Ning-po. I was then on my way to a celebrated temple in that quarter, where I intended to remain for some time, in order to make collections of objects of natural history in the neighbourhood. When the birds came in sight, I immediately made my boatmen take in our sail, and we remained stationary for some time to observe their proceedings. There were two small boats, containing one man and about ten or twelve birds in each. The birds were standing perched on the sides of the little boat, and apparently had just arrived at the fishing ground, and were about to commence operations. They were now ordered out of the boats by their masters, and so well trained were they, that they went on the water immediately, scattered themselves over the canal, and began to look for fish. They have a beautiful sea-green eye, and, quick as lightening, they see and dive upon the finny tribe, which, once caught in the sharp-notched bill of the bird, never by any possibility can escape. The cormorant now rises to the surface with the fish in its bill, and the moment he is seen by the Chinaman he is called back to the boat. As docile as a dog, he swims after his master, and allows himself to be pulled into the San-pan, where he disgorges has prey, and again resumes his labours. And, what is more wonderful still, if one of the cormorants gets hold of a fish of large size, so large that he would have some difficulty in taking it to the boat, some of the others, seeing his dilemma, hasten to his assistance, and with their efforts united capture the animal and haul him off to the boat. Sometimes a bird seemed to get lazy or playful, and swam about without attending to his business; and then the Chinaman, with a long bamboo, which he also used for propelling the boat, struck the water near where the bird was, without, however, hurting him, calling out to him at the same time in an angry tone. Immediately, like the truant school boy who neglects his lessons and is found out, the cormorant gives up his play and resumes his labours. A small string is put round the neck of the bird, to prevent him from swallowing the fish which he catches; and great care is taken that this string is placed and fastened so that it will not slip farther down upon his neck and choke him, which otherwise it would be very apt to do. Since I first saw these birds on the Ningpo canal I have had opportunities of inspecting them and their operation in many other parts of China, more particularly in the country between the towns of Hang-chow-foo and Shanghae. I also saw great numbers of them on the river Min, near Foo-chow-foo. I was most anxious to get some living specimens, that I might take them home to England.—*Fortune's Wanderings, from page* 104 *to* 111. The Chinaman from whom I bought these birds has a large establishment for fishing and breeding the birds about thirty or forty miles from Shanghae, and between that town and Chapoo. They sell at a high price even amongst the Chinese themselves—I believe from six to eight dollars per pair, that is, from 30s. to 40s. As I was anxious to learn something of their food and habits, Mr. Medhurst, jun, interpreter to the British Consulate at Shanghae, kindly undertook to put some questions to the man who brought them, and sent me the following notes connected with this subject:—"The fish catching birds eat small fish, yellow eels and pulse jelly. At 5 P. M. every day each bird will eat six taels (eight ounces) of eels or fish, and a catty of pulse jelly. They lays eggs after three years, and in the fourth or fifth month. Hens are used to incubate the eggs. When about to lay, their faces turn red, and then a good hen must set upon them. The date must be clearly written upon the shells of the eggs laid, and they will hatch in twenty-five days. When hatched, take the young and put them upon cotton, spread upon some warm water, and feed them with eel's blood for five days. After five days they can be fed with eel's flesh chopped fine, and great care must be taken in watching them. When fishing, a straw tie must be put upon their necks, to prevent them from swallowing the fish when they catch them. In the eighth or ninth month of the year they will daily descend into the water at ten o'clock in the morning, and catch fish until five in the afternoon, when they will come on shore. They will continue to go on in this way until the third month, after which time they cannot fish until the eighth month comes round again. The male is easily known from the female, in being generally a larger bird, and in having a darker, and more glossy feather, but more particularly in the size of the head, the head of the male being large and that of the female small." Such are the habits of this extraordinary bird. As the months named in the note just quoted refer* to the Chinese calendar, it follows that these birds do not fish in the summer months, but commence in autumn, about October, and end about May—periods agreeing nearly with the eighth and third month of the Chinese year.—*Fortune's Wanderings, pages* 104 to 113.

(3616) FISHES OF EASTERN AND SOUTHERN ASIA, being Catalogue of Malayan Fishes. By Theodore Cantor, *Esq. M. D. Bengal Medical Service.*

[Localities printed in *Italics* signify those from whence the fishes were obtained; in ordinary type those previously given

by authors. The descriptions are drawn up from recently taken specimens.]

Subclass. TELEOSTEI. Order. ACANTHOPTERI. Fam. PERCOIDÆ.

Genus LATES, *Cuvier and Valenciennes*, 1828. Infraorbital and humeral bones, and preopercle strongly toothed, the latter with a spine at the angle; anterior dorsal fin higher but shorter than in *Perca* and *Labrax*; tongue smooth.

(3617) *Lates heptadactylus*, (Lacepede.)

SYN. Perca maxima, Sonnerat (MS. ?) Cuv. and Val. II. 96.
Holocentre heptadactyle, Lacepede, IV. 344 and 391.
Russell, CXXXI. Pandoomenoo.

Lates nobilis, Cuv. R. A. II. 134 (n).
Lates nobilis, Richardson: Report, 1845, 222.
Lates nobilis, Bleeker: Verh. Batav. Genoots. XXII. 16, 27.
Ikan Siyakup of the Malays.

Head and back brownish, or blackish pale green, sides silvery grey; scales with a brownish spot at the root, or edged with that colour; abdomen silvery; pectorals and ventrals pale yellow, the other fins brownish or blackish. Iris blackish golden; pupil cornelian red. D 7 or 8—1/11 or 12, C 18 or 17$\frac{3}{4}$, A 3/8 or 9, V 1/5, P. 17 or 18 Br. VII. (Russell: D 7—1/13, C 18, A 3/9, V 1/5, P 15. Buchan: D 7—1/12, C 18, A 3/11, V 1/5, P 17. Cuv. and Val: D 7 or 8—1/12, A 3/8 or 9.) Inhabits the *Sea and estuaries of Pinang, Malayan Peninsula, Singapore.* Bay of Bengal, estuaries of the Ganges, Indian Ocean, China Sea, Canton, Java, Madura. Total length, 5 feet. Those inhabiting brackish water are of a muddy flavour, and blackish or of much darker colours than those living in the sea. The species appears to be less numerous in the Straits of Malacca than in Bengal. Both in fresh and in dried state, it is highly valued as an article of food. It also yields isinglass, of which however, in the Straits, but little is collected, partly on account of the comparative scarcity of the fish, and partly owing to the thinness of the air-vessel. That of a large-sized fish when dried, weighs upwards of one ounce. At Pinang this kind sells at the rate of 25 to 30 Spanish Dollars pr. Pikul.

Genus APOGON, *Lacepede*, 1802. Scales large, deciduous; the two short dorsals widely separated; margin of the preopercle double, finely toothed; pyloric appendages few.

(3618) *Apogon pœcilopterus*, Kuhl. and Van Hasselt?

SYN. ? Apogon pœcilopterus, Cuv. and Val. II. 154.

Head above, back and upper half of the sides reddish brown; lower half and abdomen mother of pearl; crown and sides of the head minutely dotted with black; opercles silvery; on the tail, in the middle of the base of the caudal, a large rounded blackish spot; membrane between first, second and third spines black; rest hyaline, minutely dotted with brown; posterior dorsal, caudal and anal, pale yellowish, dotted with pale brown, ventrals pale yellowish; pectorals hyaline. Iris mother of pearl, upper half black. D 6—1/9, C 15$\frac{6}{7}$, A 2/8, V 1/5, P 13, Br. VII. Inhabits *Sea of Pinang, Singapore.* Total length, 4$\frac{7}{8}$ inch. The length of the head is $\frac{1}{3}$ of the total; the orbit borders on the profile, and occupies the second fourth of the head; the distance between the orbits across the forehead is $\frac{3}{4}$ of the horizontal diameter of the orbit, which is $\frac{1}{4}$ of the length of the head. The posterior margin of the preopercle is finely serrated nearly all round, except a small portion of the lower part; the opercle terminates in a broad triangular membranous point, in the upper margin of which appears a deep rounded incision. The vertical diameter at occiput is $\frac{2}{3}$, in front of the anterior dorsal a little less than the length of the head, at the root of the caudal it slightly exceeds $\frac{1}{3}$ of the head. The sides are covered by 11 longitudinal series of rounded, finely ciliated scales, each with 15 to 18 radiating lines at the base. The lateral line follows the outline of the back; it occupies the third upper series of scales, 23 or 24, on each of which appears a central, longitudinal tube, with one or two minute tubes on each side of its root. The scales of the series immediately above and below the lateral line present an indistinct longitudinal elevation. The first dorsal spine is $\frac{1}{4}$ of the second and third, the longest and strongest, each of which is 2$\frac{1}{2}$ of the length of the head; the sixth spine exceeds the first by one third; the spine of the posterior dorsal, the second anal and the ventrals are of equal length, $\frac{1}{3}$ of that of the head. In the inconstant character of colours, the present species differs from *A. pœcilopterus*, but both agree in their number of fin rays, and general resemblance to the Mediteranean species. (*A. rex mullorum*, Cuv. and Val. II. 143). It is to be regretted that the description of *A. pœcilopterus* is not sufficiently explicit for identification. At Pinang and Singapore single individuals of the present species are of uncertain occurrence.

(3619) *Apogon quadrifasciatus*, Cuv. and Val.

SYN. ? Mullus fasciatus, White; Voyage, 268, Fig. 1.
Apogon quadrifasciatus, Cuv. and Val. II. 153,
Apogon quadrifasciatus, Bleeker: Verh. Batav. Gen. XXII. 16, 28.

Crown of the head and back brownish black; sides and abdomen, mother of pearl; a broad black band from above the orbit to the root of the caudal; a second parallel from behind the orbit, first beneath the lateral line, but from near

the posterior part of the second dorsal it intersects the lateral line, continuing above it through the middle of the caudal fin; upper half of anterior dorsal, between 3d and 6th spine, more or less intense black; the other fins pale yellowish, or pale crimson; all except the pectorals with broad blackish margins. Iris silvery with large black spots. D 7—1/9, C 17$\frac{5}{6}$, A 2/8, V 1/5, P 16, Br. VII. Inhabits *Sea of Pinang, Singapore.* Pondicherry, Batavia. Total length, 4$\frac{1}{8}$ inch. In the young the two lateral black bands, and the blackish margins of the fins are very indistinct, or scarcely perceptible. All the species of the fins exhibit traces of transversal striæ. This species is not numerous at Pinang.

(3620) *Apogon fucatus*, Cantor.

Body and fins, except the pectorals, silvery carmine with rainbow reflections, cheeks, throat and abdomen paler; from the lower part of the orbit to the muzzle a gamboge oblique line; at the root of the caudal a large round black spot, surrounded by numerous minute brown dots, and a few similar on the scales of the posterior part of abdomen. Pupil circular, black with crimson reflection; iris golden gamboge, the upper fourth part ultramarine. D 6—1/9, C 18$\frac{4}{4}$, A 2/16, V 1/5, P 13, Br. VII. Inhabits *Sea of Pinang.* Total length, 2$\frac{6}{8}$ inch. The length of the head is contained about 3$\frac{1}{2}$ times in the total; its depth, which is little less than that of the body, equals its length; the eye is large, circular, the diameter slightly exceeding $\frac{1}{3}$ of the length of the head; the mouth small, little protractile; gape subvertical; the angle of the mouth a little in front of the anterior margin of the orbit; teeth excessively minute; margin of preopercle very finely toothed; lateral line following the outline of the back, nearly throughout oblique, becoming horizontal close to the root of the caudal. Examined under a lens, the spines of all the fins are transversely striated, as in the Genus *Chanda.* The spines of the anterior dorsal are very slender, as in *A. macropterus*, Kuhl and Van Hasselt, and scarcely arched. The lower part of the anterior margin of the second spine is armed with three blunt teeth, vertically situated. The second, third and fourth spine, are of nearly equal length; about one half of the vertical diameter of the body. The spine of the posterior dorsal fin equals in length the longest anterior, but the second branched ray, which slightly exceeds the first and third, is $\frac{2}{3}$ of the vertical diameter of the body. The distance between the last, double, ray of the posterior dorsal, and the root of the caudal equals the length of the head. The caudal is slightly forked: the length of the centre $\frac{1}{6}$ of the total. The basal extent of the anal is a little less than the length of the head; the second and third branched rays are the longest, equalling the corresponding rays of the posterior dorsal fin. The distance between the sixteenth double anal ray, and the root of the caudal is but about one half of that between the latter and the last ray of the posterior dorsal, or about $\frac{1}{3}$ of the length of the head. The first branched ray of the ventrals equals in length the second spine of the anterior dorsal. The length of the transparent pectorals is about $\frac{2}{3}$ of the vertical diameter of the body. This species is closely allied to *Apogon lineolatus*, Ehrenberg, the peculiar coloration is strikingly similar in both, but it differs from the latter, and the other species, in the greater number of anal rays, and in the toothed appearance of the second dorsal spine. A single specimen was observed at Pinang in July 1845. The fishermen asserted it to be of very rare occurrence. The very capacious stomach, occupying the whole length of the abdominal cavity, was expanded with minute shrimps; the intestinal canal is less than one third of the total length, and without cœcopyloric appendages. The rounded acoustic bones are, for the size of the fish, remarkably large.

Genus CHANDA,* *Buchan. Ham.* 1822. (*Ambassis,*† Cuv. and Val. 1828.—*Hamiltonia,*‡ Swainson, 1839.) Teeth sharp, scattered in both jaws, with some of the bones of the head distinctly indented on the edge; with prickles in some of the fins, and with bodies more or less diaphonous, and much compressed; the sides nearly perpendicular. *Notes.* * Not from χανδὸς, hians, as stated by mistake in *Nomenclator Zoologicus*, (Pisces, p. 15,) but from *Chanda*, the vernacular name, applied in Bengal to the Genus. (*Chandee*, Hind. Silver.) † MM. Cuvier and Valenciennes observe that the two first species of *Chanda*, described by Buchanan, belong to a different genus, and they have for that reason cancelled *Chanda.* ‡ Buchanan himself expressed doubts as to the propriety of placing his first species in that genus. Fam. *Zenidæ* (*Scombroidæ*, Bonap.) Swainson, *Fishes, &c.* Vol. II. p. 250. "*Hamiltonia ovata*, Sw., Ham. fig. 37, and *H. lata*, Sw., Ham. fig. 37." Both references are errata.

(3621) *Chanda dussumieri*, (Cuv. and Val.)

Syn. Ambassis dussumieri, Cuv. and Val. II. 181.
Ambassis dussumieri, Bleeker: Verh. Bat. Gen. XXII. 17, 30.

Crown of the head and the back pale greenish, minutely dotted with black, opercle bluish silvery; sides pale silvery with a narrow longitudinal shining silvery band from the opercle to the caudal fin; abdomen transparent with the silvery peritoneum shining through. Fin-membranes transparent; that connecting the 2d and 3d dorsal spine, minutely dotted with black and with a black margin; caudal in some with a blackish margin. Iris silvery; the upper fourth part black. D 7—1/9. C 17$\frac{5}{6}$, A 3/9, V 1/5, P 17, Br. VI. Inhabits *Sea of Pinang.* Malabar, Java, Madura. Total length: 3 inch. The vertical

diameter of the body is contained about 3½ times in the total length. This species appear to occur but rarely at Pinang. In three examined there was no external appearance of the horizontal spine in front of the first dorsal.

(3622) *Chanda nalua*, Buchan. Ham.

Syn. Chanda nalua, Buch. Ham. 107, Pl. 6, Fig. 36.
Ambassis nalua, Cuv. and Val. II. 182.
Ambassis nalua, Bleeker: Verh. Bat. Gen. XXII. 17, 29.

Crown of the head and back pale greenish, with a few indistinct blackish spots at the dorsal fins; sides pale silvery, with a narrow longitudinal shining silvery band from the opercle to the caudal fin; cheeks and opercles iridescent silvery, the latter with a blackish spot between the angle and the orbit, produced by numerous blackish dots; abdomen transparent, iridescent, with the silvery peritoneum shining through: fins pale citrine, the membrane of the anterior dorsal minutely dotted with black, particularly between the 2d and 3d spine, with a black margin. Iris silvery with a black spot beneath the upper margin of the orbit; pupil circular, black with crimson reflection. D 7—1/9, 10 or 11, C 17/7, A 3/9 or 10, V 1/5, P 15, Br. VI. Inhabits *Sea of Pinang*, Rivers of Lower Bengal, Batavia, Samarang, Surubaya, Bima, Sumbawa. Total length: 4⅛ inch. As observed by MM. Cuvier and Valenciennes this species differs from *Chanda gymnocephala* (Lacépede). Syn. *Sciæna safgha* Forskal?—*Lutjanus gymnocephalus*, Lacep.—*Centropomus ambassis*, Lacep.—*Ambassis commersonii*, Cuv. and Val. II. 17. Pl. 25) by its comparatively shorter head, blunter muzzle, and greater depth of the body. Besides, it may at once be distinguished by the extent of the membrane connecting the anterior to the posterior dorsal, which in the present species attaches itself to the lower third of the spine of the posterior dorsal, but does not as in *Chanda gymnocephala* descend nearly down to the level of the back. From the individuals described by Buchanan, those inhabiting the sea differ slightly in colours, and in having one, rarely two, branched rays less in the posterior dorsal and anal fins. The species is at all seasons of no rare occurrence at Pinang. It feeds on small *Crustacea*. The preceding species of *Apogon* and *Chanda* are of little value as articles of food. At Pinang they, as well as numerous other small fishes, the daily residue of the market, are used as manure.

Genus SERRANUS, *Cuv. and Val.* 1828. Dorsal fin single; preopercle serrated; opercle with two or three flat spines; teeth velvety, with a greater or smaller number of longer, pointed teeth; crown of the head, opercles, and cheeks covered with scales; muzzle and jaws with more or less perceptible scales, or aparently naked.

(3623, *Serranus hexagonatus*, (Forster).

Syn. Perca hexagonata, Forsrer.
Holocentrus hexagonatus, Bloch. Schneider.
Serranus hexagonatus, Cuv. and Val. II. 330.
Serranus stellans, Richardsor, Ann. Nat. Hist. March 1842.
Serranus hexagonatus. Richardson: Voy. Sulph. 82, Pl. 38, Fig. 1.

Ground colour of the head above, back and upper half of the sides pale reddish brown with numerous rounded, frequently confluent spots, all indistinct and of a shade but slightly darker than the ground colour; lower half of the sides diluted reddish brown, becoming whitish on the abdomen; fins reddish brown, darker than the body from their numerous indistinct spots, the largest of which along the back between the dorsal spines; upper margin of the dorsal membrane black; all the spines greyish brown. Iris reddish brown, with a narrow golden ring. D. 11/17, C 17-⅔, A 3/8, V 1/5, P. 17, Br. VII. Inhabits *Sea of Pinang* Isles of Borabora and Oualan, South Pacific. Total length: 7⅜ inch. The length of the head is 3¼ of the total; the vertical diameter at occiput is ⅔ of the length of the head; the greatest oblique diameter of the orbit is about 4½ of the length of the head; the margin of the preopercle is rounded, the ascending part strongly toothed, the three lowest teeth larger than the rest; of the three spines of the opercle the upper one is the smallest, and the centre one the largest, its length equalling ½ of the diameter of the eye; the membranous portion of the opercle is elongated to a sharp point. The upper maxillary teeth are preceded on each side by a single curved canine, inside of which appear several pointed teeth, conspicuously longer than all the rest. The lower maxillaries have two canines on each side of the symphysis. All the fins are rounded; the dorsal spines are rather slender and a little shorter than the soft rays; the second anal spine is longer and stronger than any of the other spines, its length equalling the extent of the base of the anal fin. The greatest vertical diameter of the body slightly exceeds ¼ of the total length. The stomach is moderate, coriaceous, particularly near the fundus; the appendicula cœcopylorica are of equal length, about ⅝ inch; the length of the intestinal canal is a little less than the total. This species, of which a single individual occurred at Pinang in 1845, agrees with the description of *Serranus stellans*, Richardson, which the author later referred to *S. hexagonatus*. In the Pinang specimen the dark spots disappeared shortly after death, leaving behind a uniform reddish brown colour.

(3624) *Serranus lanceolatus*, (Bloch.)

Syn. Holocentrus lanceolatus, Bloch. Pl. 242, Fig. 1.

Serranus lanceolatus. Bleeker: Verh. Batav. Gen. XXII. 9, 18, 35.
"Ikan Krapu" of the Malayas.

Ground-colour of the body and fins bright gamboge, with five broad vertical brown or black bands, of which the first from the orbit over the preopercle, the second from the crown of the head obliquely over the opercle to behind the pectoral fins, where it joins the third; in the obliquely oval space between these two bands some individuals have a large oval black spot; the third band, which occupies the space between the 2nd and 10th dorsal spine, becomes narrower on the body and continues jointly with the second band over the abdomen; the fourth band spans nearly the whole lower half of the dorsal rays, proceeds over the body and the anal, on the posterior part of which the ground colour is visible, with one or more black spots; the fifth band is in front of the caudal; all the fins with one or more series of large black spots, more or less confluent; the pectorals in some with three arched undulating black bands; jaws with large black spots. Pupil circular black; iris golden. In the young the ground colour is citrine or sulphur. D 11/16, C 17$\frac{4}{4}$, A 3/8, V 1/5, P 18, Br. VII. Inhabits *Sea of Pinang*, Bay of Bengal, Batavia, Samarang. Total length: 6$\frac{4}{8}$ inch. In three individuals examined the number of fin rays was the above stated; Russell and M.M. Cuvier and Valenciennes give the dorsal 11/14, and the latter give the anal 3/10.

(3625) *Serranus horridus*, Kuhl and Van Hasselt.

Syn. Serranus horridus, Cuv. and Val. II. 321.
Serranus horridus, Bleeker: Verh. Bat. Gen. XXII. 7, 19, 36.
"Ikan Krapu" of the Malays.

Crown of the head and back blackish brown; sides and abdomen brownish grey, largely marbled with blackish brown; spinous part of the dorsal yellowish pale brown, with a large basal brownish spot, between each pair of spines: the rest of the dorsal gamboge, the lower half with three or four oblique downward directed blackish bands, above which some large round black spots; caudal, anal and ventral fins gamboge, with large round, sometimes confluent, black spots; pectorals with a large black spot in the centre of the base, and three or four more or less interrupted arched black bands. Iris blackish brown with a golden ring. D 11/15 or 16, C 17$\frac{3}{3}$, A 3/8, V 1/5 P 17 or 19, Br. VII. Inhabits *Sea of Pinang*, *Singapore*, Java. Total length; 4 feet 3 inch. This species is closely allied to *Serranus geographicus*, Kuhl and Van Hasselt, which according to M.M. Cuvier and Valenciennes has one or two additional soft rays in the dorsal, and two in the anal fin. It attains to gigantic size. In one, the weight of which exceeded 130 lb., the stomach contained remains of *Stromateus*, *Sphyrna blochii*, and of a *Limulus*. Though not plentiful, it is not of uncommon occurrence at Pinang, where it is valued by the natives both in its fresh and dried state. In the adult the colour of the fins is greenish olive.

(3626) *Serranus altivelis*, Cuv. and Val.

Syn. Serranus altivelis, Cuv. and Val II. 314 Pl. 25.
Cromileptes altivelis, Swainson, Nat. Hist. of Fishes, II. 201.
Serranus altivelis, Richardson: Report 1845, 230.
Serranus altivelis, Bleeker, Verh. Batav. Gen. XXII. 18, 33.

Head and body brownish buff changing to white on the abdomen; fins lilac-grey; all parts with distant round black spots, edged with white; those of the body and dorsal fins larger than the rest; iris brownish buff with a narrow golden ring, the upper part with two ocelli. D 10/18, C 17$\frac{5}{5}$ A 3/10, V 1/5, P 17, Br. VII. Inhabits *Sea of Pinang*, Java, China Seas. Total length: 4$\frac{6}{8}$ inch. M.M. Cuvier and Valenciennes count 19 soft rays in the dorsal fin, but their figure represents 18; the latter is probably taken from a perserved specimen, and gives but an inadequate idea of the exquisitely delicate tints of the living fish. A single, probably young individual observed at Pinang in June 1845, farther differs from Pl. 25, *Hist. Nat. des Poiss.* in having the dorsal spines from the third of equal length, whereas in the plate, their length is represented as gradually increasing from the first to the tenth. The very capacious stomach was expanded with remains of *Crustacea*.

(3627) *Serranus bontoo*, Cuv.

Syn. Russell CXXVIII. Madinawa Bontoo.
Serranus bontoo, Cuvier R. A. II. 141,(3)
Serranus bontoo, Cuv. and Val. II. 334.
Serranus bontoo: Bleeker: Verh. Bat. Gen. XXII, 9.

Brownish grey, lighter on the abdomen; head and body with numerous round blackish spots; fin membranes brownish grey; the dorsal blackish at the base and upper half. Iris pale greenish olive with a narrow golden ring. D 11/17, C 17$\frac{5}{5}$, A 3/8, V 1/5, P 19, Br. VII. Inhabits *Sea of Pinang*, Madras, Vizagapatam, Java. Total length: 5 inch. A single individual with one soft anal ray less, but otherwise corresponding to the description and figure of Russell, was observed at Pinang in 1843. The lowest three teeth of the preopercle are larger than the rest. On each side of the intermaxillary bone appears a canine, stronger than the rest of the teeth. The black spots of the body become indistinct after death.

(3628) *Serranus coioides*, (Buchanan Hamilton).

Syn. Russell CXXVII, Bontoo.
Bola ? coioides. Buchanan Ham. 82. 369. An unfinished coloured sketch in the depulicate series of Buchanan's Drawings leaves no doubt of the species in question.
Serranus suillus, Cuv. and Val. II. 335.
Serranus suillus, Bleeker: Verh. Bat. Gen. XXII, 9.

Head, body and fins reddish ash-coloured, whitish on the abdomen, with numerous rust-coloured or orange round spots, those of the dorsal sometimes confluent, forming one or two longitudinal bands. Iris pale golden with one or two rusty spots. D 11/15, C 17⅔, A 3/8, V 1/5, P 18, Br. VII. Inhabits *Sea of Pinang*, *Singapore*, Coromandel, Bay of Bengal, Gangetic estuaries, Java. Total length: 1 foot 6 inch. This species grows to a gigantic size. Russell saw one 7 ft. in length, 5 in circumference, weighing more than 300 lb. Smaller individuals are highly valued as articles of food. It is not numerous at Pinang.

Genus GENYOROGE, *Cantor*. γωγὴ cheek; γένυ cleft. Substituted for *Diacope*, Cuvier 1187, preoccupied by *Diacope*, Hubner 1816, (*Lepidopt.*) (*Equivalent to* Diacope, *Cuvier*.) Canines among the velvety maxillary teeth; margin of preopercle toothed; opercle generally terminating in two or three flat points; margin of preopercle with a notch receiving a tuberosity of the interopercle.

(3629) *Genyoroge notata*, (Cuv. and Val.)

Syn. Russell XCVIII, Antika Doondiawah.
Diacope notata, Cuv. and Val. II. 422.
Mesoprion Russelli, Bleeker: Verh. Batav. Gen. XXII. 20, 41.

Head above crimson; cheeks golden, margin of preopercle pale carmine: of opercle vermilion; back reddish brown; sides pale golden with red reflections; abdomen yellowish white; from the orbit, above the lateral line, three obliquely ascending orange lines, of which the lowest reaches the middle of the base of the dorsal rays; beneath which a large black spot; beneath the lateral line three or four parallel similar lines, of which the uppermost divides the black spot; the rest nearly straight from the opercle towards the tail; fin membranes yellowish; apical third of dorsal spines and rays, and upper, lower and posterior margin of caudal fin crimson; anal and ventral fins gamboge. Iris golden. *Young.*—Head above and back brownish; cheeks, sides and abdomen, silvery white; stripes of the body brown; fine pale yellow, points of dorsal rays and posterior margin of caudal fin pale crimson. D 10/14, C 17¼, A 3/8, V 1/5, P 16, Br. VII. Inhabits *Sea of Pinang*, Indian Ocean, Bay of Bengal, Batavia. Total length: 9 inch. Russell gives 3/6 in the anal; M.M. Cuvier and Valenciennes 11/13 in the dorsal fin. Russell has observed the changes of colour produced by age. On each side of the throat appear three small oval fossets, of which the posterior is the largest. The species is not numerous at Pinang.

Genus MESOPRION, *Cuvier* 1829. Teeth on the palate and vomer; canines among the velvety maxillary teeth; the middle of each side of the head armed with teeth like those of a saw.

(3630) *Mesoprion Johnii*, (Bloch).

Syn. Camboto, Renard T. I. Pl. 31.
Anthias johnii, Bloch, IX. 97, Pl. 318.
Lutjanus johnii, Lacepede IV. 235.
Sparus tranquebaricus, Shaw IV. 471.

Mesoprion unimaculatus, Quoy and Gaim. Zool. de Freyc. 304, Pl. 5. fig. 3.
Mesoprion unimaculatus, Cuv. R. A. II. 143,(3).
Mesoprion johnii, Cuv. and Val. II. 443.
Mesoprion unimaculatus, Cuv. and Val. II. 441.
Mesoprion unimaculatus, Richardson: Report 1845, 229.
Mesoprion unimaculatus, Bleeker: Verh. Bat. Gen. XXII. 4, 20, 42.

Head above and back greyish green, opercles silvery with golden edges; sides silvery with numerous longitudinal blackish lines, produced by a central spot or line on each scale; beneath the middle of the base of the dorsal rays a large black spot, in front of which, in some, two or three blackish vertical bands, terminating a little below the lateral line; abdomen yellowish white or silvery; fins reddish yellow; upper margin of the membrane of the dorsal spines blackish; of that of the rays and posterior margin of the caudal fin pale carmine. Iris pale golden. D 10/14, C 17⅔, A 3/8, V 1/5, P. 16 or 17, Br. VII. Inhabits *Sea and estuaries of Pinang*, *Malayan Peninsula*, Indian Ocean, Bay of Bengal, Gangetic estuaries, island of Lantao (Canton River), China Seas, Celebes, Amboina, Batavia, Tagal, Samarag, Surubaya, Pasuruan. Total length: 10 inch. The intensity of the black lateral spot and lines differs individually, and such as habitually live in brackish muddy water, have a general blackish hue, and two or three vertical blackish bands in front of the constant lateral spot. Such was the individual first described by Bloch as *Anthias johnii*, which denomination therefore takes precedence. M.M. Cuvier and Valenciennes, indeed, question the specific difference between the latter, and *Mesoprion unimaculatus*, and point out the identity of *Coius catus*, Buch. Ham. and the present species. The first ventral ray is elongated, but it is frequently mutilated. In some, not in all individuals, the margin of the preopercle is so deeply indented, and the tuberosity of the in-

teropercle so conspicuous, that they might be considered species of *Genyoroge*, and as such they were considered by Kuhl. On each side of the throat appear three small oval fossets as in *G. notata*. At Pinang this species is numerous at all seasons. It is insipid; the natives however dry it.

(3631) *Mesoprion rangus*, Cuv and Val.

Syn. Russell XCIV. Rangoo.
Mesoprion rangus, Cuv. and Val. II. 481.
Mesoprion rangus, Cuv. R. A. II. 144,(3).

Head, body and fins cherry or indian-red, lighter on the sides and abdomen; the latter in some reddish white. Iris silvery carmine. *Young.*—Head and back purple; cheeks and sides pale indian-red; abdomen reddish white. D 10/13, 14 or 15, C 17$\frac{3}{3}$, A 3/8, V 1/5, P 16, Br. VII. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula*, Java, Coromandel. Total length: 1 foot 8 inches. In the upper jaw appear on each side of the muzzle two canines, of which the posterior are very large, slightly curved; on each side of the lower jaw are four similar, conical and equidistant. In the adult of this as in other species, the teeth of the margin of the preopercle become worn and indistinct. The very large, scaleless, subrhombic infraorbital bone, affords a distinguishing character. According to Russell this fish is not much esteemed. At Pinang and Singapore, where single individuals occur at all seasons, it is of excellent flavour, and considered a great acquisition to the table. At Malacca it is plentiful, and in our settlements in the Straits it is known under the denomination of the "red rock-cod."

(3632) *Mesoprion annularis*, Cuv. and Val.

Syn. Mesoprion anularis, Cuv. and Val. II. 484, III. 497.
Diacope annularis, Rüppell: Atlas, 74.
Diacope annularis, Rüppell, Neue Wirb. Fische. 91.
Quoy et Gaimard, Astrol: Pl. 5, fig. 4.
Mesoprion annularis, Richardson: Rep. 1845, 229.
Mesoprion annularis, Bleeker: Verh. Bat. Gen. XXII., 4, 22, 47.

Head above and back brown with crimson hue, paler on the cheeks and sides; abdomen silvery rose-coloured; in front of the root of the caudal fin, on each side, a large round black spot: both joined on the back, and both with a broad white margin, except on the back; dorsal spines crimson: the lower half of the rest of the dorsal fin reddish brown, the upper half crimson; the anterior half of the caudal fin reddish brown; posterior half pale crimson; the upper half of the anal silvery reddish brown, the rest black; pectorals pale rose-coloured. Iris golden with crimson hue. *Young.*—Colours generally paler and the black marks less distinct. D 11/13 or 14, C 17$\frac{3}{3}$, A 3/9, V 1/5, P 16 or 17, Br. VII. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula*, Indian Ocean, Massaua (Red Sea), Ceylon, China Seas, Batavia, Bantam, Cheribon, Samarang, Surubaya, Pasuruan, Patjitan, Celebes. Total length: 7 inches. The brown oblique lines of the body, described by M.M. Cuvier and Valenciennes, do not exist during life, but appear after death, as the original colours fade. The ascending margin of the preopercle is very minutely toothed, but the lower part is very strongly so; the latter is arched, but there is scarcely any notch where it joins the ascending straight part. This species is distinguished by the beauty of its colours no less than by the symmetry of its forms. It feeds upon *crustacea*. A few occur at times at Pinang.

(3633) *Mesoprion gembra*, (Bloch-Schneider.)

Syn. Alphestes sambra, and gembra, Bloch-Schneider. page 236 Pl. 51, fig. 2.
Mesoprion gembra, Cuv. and Val. II. 485.
Mesoprion gembra, R. A. II. 144, (3).

Upper part of the head and the back blackish brown: cheeks and sides silvery brownish grey; abdomen whitish: from occiput to the tail numerous (from 10 to 15) vertical brownish black bands, terminating near abdomen, with intervals narrower than the bands themselves: apical part of dorsal spines and margin of their membrane pale crimson; the membrane with a transversal series of brownish spots; upper third of the rest of the dorsal fin pale blackish, central third whitish, basal pale yellowish brown; anterior third of the caudal fin pale yellowish brown, central whitish, posterior blackish; lower third of anal blackish, the rest successively as the caudal; pectorals and ventrals whitish, the lower half of the two anterior ventral rays, and their connecting membrane pale crimson, a large brownish central spot between the 2d, 3d and 4th ventral ray. Iris pale golden, blackish near the orbit. *Young.*—Ground colour and black bands less distinct; between the dorsal rays some irregular series of brownish dots; posterior half of ventral fins blackish; no crimson on this nor the dorsal fin. D 10/13 or 14, C 17$\frac{3}{3}$, A 3/8, V 1/5 P 17, Br. VII. Inhabits *Rivulets of Pinang*, Tranquebar, according to Bloch. Total length; 5$\frac{2}{3}$ inch. The anterior ventral ray is elongated, bristle-like. In the peculiar distribution of colours this species much resembles a *Datnia* from the estuaries of the Ganges described and figured by Buchanan Hamilton as *Coius polota*, (pp. 25, 270, Pl. 38, fig. 31.) Referred by M.M. Temminck and Schlegel as a second species of their genus *Anoplus*. This latter name however is inadmissible, as it has been preoccupied by *Anoplus*, Schonherr, 1826, (*Coleopt.*) From Coius polita the present differs not only in the number of its branchiostegous and fin-rays, but also by its more elongated form. But two individuals were at different times ob-

served at Pinang: both were taken in rivulets, which however communicate with the sea.

(3634) *Mesoprion caroui*, Cuv. and Val

Syn. Mesoprion caroui, Cuv. and Val. II. 489. Russell CXXV. Karooi.

Head above and back reddish brown; cheeks and sides silvery brownish yellow; abdomen white; between the back and the lateral line a number of more or less distinct oblique brownish lines: from the posterior margin of the orbit a reddish light brown band to the tail; from the opercle four undulating reddish lines, converging towards the tail; fins brownish yellow. Iris brownish golden. D 11/12, C 17$\frac{5}{5}$, A 3/8 or 9, V 1/5, P 16, Br. VII. Inhabits *Sea of Pinang*, Madras, Vizagapatam. Total length, 4$\frac{3}{8}$ inch. Russell counted 9 anal rays: a single individual observed at Pinang had but 8. The margin of the preopercle is finely toothed, except at the angle where the teeth are stronger.

Genus NANDUS, *Cuv. and Val.* 1831. Mouth very protractile, with velvety teeth in both jaws, on the palate and vomer; margin of preopercle and interopercle finely toothed; spine of opercle very minute.

(3635) *Nandus marmoratus*, Cuv. and Val.

Syn. Coius nandus, Buchan. Ham. 96, 370, Pl. 30, Fig. 32.
Nandus marmoratus, Cuv. and Val. VII, 482, Pl. 207.
(*Icon.*) Bedula hamiltonii, Gray, Ill. Ind Zool. II. Pl. 88, Fig. 3.
Bedula nebulosus, Gray, *Ibid.* Fig. 2.
Coius nandus, McClelland, Calc. Jour. Nat. Hist. II. 574.

Head and body silvery or golden greenish olive, lighter on the sides; cheeks and abdomen silvery with rose-coloured or orange reflection; on the head and body large dark olive patches, edged with black dots, in some disposed like irregular vertical bands; on the cheeks two or three such, radiating from the orbit; in most a greenish black oval spot on the middle of the side of the tail; spines and fin-membranes transparent, minutely dotted with black, marbled with pale brownish lake and greenish olive; pectoral rays pale greenish olive, minutely dotted with black; rest of the rays pale brownish red with transversal greenish black bars. Iris golden greenish olive, minutely dotted with black, with a narrow golden circle round the pupil; upper orbital margin black. D 13/12, C 12$\frac{3}{3}$, A 3/7, V 1/5, P 16, Br. VI. Rarely: D 12/13 or 13/11 or 14/12, C 17 or 18$\frac{3}{3}$, A 3/8 or 9, P 17 or 18. Inhabits *Fresh water Malayan Peninsula*, Bengal (in ponds), Sutlej, Chenaub (at Ramnuggur). Total length, 6 inch. The length of the head is about $\frac{1}{3}$ of the total; the vertical diameter at occiput is 1$\frac{1}{3}$ of the length. The eye nearly borders the profile, the diameter is in the young 4$\frac{1}{2}$, in the adult $\frac{1}{5}$ of the length of the head; the distance from the muzzle is 1$\frac{1}{2}$ diameter from the flat membranous point of the opercle 2$\frac{1}{2}$ diameter. The openings of the nostrils are situated closely in front of the orbit. Between the centre of the supraorbital margin and the muzzle appear three distant fossæ; on the infraorbital bone two or three; beneath the symphysis of the lower jaw two pores, and behind them on each branch of the jaw two fossæ. The teeth are minute inwardly pointing, like those of a card; in the intermaxillaris they are placed 3 to 4 deep, but they become more crowded beneath the symphysis, where those of the innermost series are a little, yet perceptibly, longer than the rest. Such is also the case with those of the symphysis of the lower jaw, but on the branches they are placed in a single series, and are somewhat distant from each other. The vomer is raised into an acute angular crest, surmounted by a series of minute pointed teeth; the palatal, pharyngeal and those at the root of the flattened membranous tongue, are very minute velvety. The greatest vertical depth of the body, at the seventh dorsal spine, is $\frac{3}{4}$ of the length of the head. The lateral line consists of a series of minute tubes, bifid at each extremity; it follows on the upper fourth of the side the arch of the back towards the termination of the dorsal, where it is suddenly interrupted, but it reappears lower down, and proceeds straight in the middle of the tail to the caudal. This fish is as numerous in the Malayan Peninsula as in Bengal. It is of voracious habits, preying upon small *Cyprionidæ*, and, as observed by Buchanan, is very tenacious of life. The longitudinal mark of the scales, described and figured by Buchanan, does not exist in the living fish, but appears after death. Buchanan Hamilton has correctly described the teeth: "intermixed with these, in each jaw, are several sharp teeth of a larger size." Such is the case in Bengal and Malayan specimens. Those examined by M.M. Cuvier and Valenciennes appear to have been defective in this character, and they therefore express some doubt about the identity of the species. As yet however, no other species of *Nandus* has been discovered. They have corrected the error of Buchanan in counting seven, instead of six branchiostegous rays. The figure of *Bedula nebulosa*, *Ill. Ind. Zool.* appears to be intended to represent the present species, but whether the defect is attributable to the original specimen, or to the copyist, is impossible to ascertain. The figure of *Bedula hamiltonii*, is inferior to that of Buchanan Hamilton, and the colours are those of a specimen preserved in spirits of wine.

Genus THERAPON, *Cuv. and Val.* 1829. Preopercle toothed, opercle terminating in a strong spine; dorsal fin deeply emarginated between the spinous and soft part; the external series of teeth stronger than the rest, conical; teeth of the vomer apt to fall out; air vessel divided by a stricture in two compartments.

(3636) *Therapon trivittatus*, (Buchanan Ham.)

Syn. Russell CXXVI. Keelputa.
Coius trivittatus, Buchan. Ham. 92, 370.
Therapon puta, Cuv. and Val. III. 131, and 144, ("un therapon, le trivittatus.")

Icon. Pterapon trivittatus, Grey: Ill. Ind. Zool. II. Pl. 88, Fig. 1.
Pterapon trivittatus, (Syn. Therapon theraps) Richardson's Report, 1845, 238.
Pterapon puta, Bleeker: Verh. Batav. Gen. XXII. 23, 50.

Head above and back pale greyish green, sides silvery, abdomen white; from the first dorsal ray to the middle of the base of the soft part a brownish or black slightly downward arched band; a second from the nape of the neck towards the root of the upper margin of the caudal fin; a third, paler, from the opercle to the centre of the caudal; fin-membranes white, upper half of the membrane between the six anterior dorsal spines, and in some between the ninth and tenth, black; the upper margin of the soft dorsal with one or two black spots; caudal with a central horizontal blackish band, above and below which two, more or less distinct, oblique black bands; posterior half of anal, and anterior half of ventral fins pale ochre. Iris golden; pupil broad lanceolate with the apex forward. D 11/10, C $17\frac{1}{1}$, A 3/8, V 1/5. P 13, Br. VI. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula*, Bay of Bengal, estuaries of the Ganges, Batavia. Total length, 6 inch. This species is well marked by three or four teeth at the angle of the preopercle, conspicuously larger than the rest. Buchanan Hamilton describes *Coius trivittatus* (l. c. 93), as having "the four lower toothlets" (of the preopercle) "larger than the others." In his duplicate series of drawings is a correct representation of this species, marked in his handwriting as "*Holocentrus Katkaya.*" Buchanan's drawing is evidently the original of the figure in Hardwicke's Illustrations named *Pterapon trivittatus*. In the copy however, the distinguishing character is not represented, nor is Buchanan's name affixed to the specific. The incorrectness of the copy has caused Sir John Richardson to consider it as intended to represent *Therapon theraps*, Cuv. and Val., and he consequently placed, as a synonym of the latter, *Pterapon trivittatus*, "*Gray*," an entirely distinct species, first described by Buchanan Hamilton (Richardson: Report 1845, 238.) M. M. Cuvier and Valenciennes count 12/10 or 10—1/10 in the dorsal, and 3/9 in the ventral fins. In colours the young resemble the adult, but the distinctness of the lateral bands varies individually in all ages, and in some they are greenish, instead of black. The young have velvety teeth on the vomer, but they disappear with age. In the Straits of Malacca the species is numerous at all seasons.

(3637) *Therapon obscurus*, Cuv. and Val.

Syn. Therapon obscurus, Cuv. and Val. III. 135.
Therapon obscurus, Bleeker: Verh. Batav. Gen. XXII. 23, 51.

Pale blackish or bluish silvery, with two broad longitudinal white bands on the sides; abdomen white; dorsal and caudal fins coloured like *T. trivittatus*, lower half of the anal and ventral fins blackish; body and fins minutely dotted with black. Iris pale golden, black towards the orbit. *Young.*—Of a general darker colour than the adult. D 12/10 or 11, C $17\frac{8}{8}$, A 3/8, V 1/5, P 13 or 14, Br. VI. Inhabits *Sea of Pinang*, Indian Ocean, Batavia. Total length, $4\frac{2}{8}$ inch. This species may readily be distinguished from the preceding by its shorter, broader shape, by the uniformly toothed preopercle, and the smaller spine of the opercle. From *Therapon squalidus*, Cuv. and Val. it differs in having but 7 cœcopyloric appendages. It is of rare occurrence at Pinang. In the young of this species as well as of *T. trivittatus*, the suprascapular and humeral bones are not crenulated, but they become so in the adult.

Genus SILLAGO, *Cuvier*, 1817. Head elongated, slightly pointed; mouth small; velvety teeth in the jaws and in front of vomer; opercle terminating in a small point; six branchiostegous rays; two contiguous dorsal fins, of which the anterior with thin spines, the posterior is long and little elevated.

(3638) *Sillago Malabarica*, (Bloch.Schneider.)

Syn. Sciæna malabarica, Bl. Schn. Pl. 19.
Russell CXIII. Soring.
Sillago malabarica, Cuv. R. A. II. 149.
Sillago acuta, Cuv. and Val. III. 400.
Sillago actua, Bleeker: Verh. Batav. Gen. XXII. 25, 61, 4.
"Ikan Ubi" of the Malays of Pinang.

Head above pale reddish purple; cheeks pale orange; opercles bluish silvery: back pale greenish; sides pale reddish silvery, with a silvery longitudinal band beneath the lateral line; abdomen mother-of-pearl; membrane of dorsal fins with some minute obliqne black lines, particularly near the anterior margin of the spines and rays, where they in some form faint blackish vertical lines; the rest of the fins whitish or pale yellowish. Iris pale golden. D 10 or 11—1/21, C $17\frac{1}{7}$, A 1/23, V 1/5, P 15, Br. VI. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Bay of Bengal, estuaries of the Ganges, Macao. Bantem, Batavia, Tjilatijap, Samarang, Surabaya, Passuruan, Bangkallang, Makassar, Celebes, Sumbawa. Total length, 1 foot. The length given of the present species is the greatest observed, but M. Leschenault has seen single individuals upwards of three feet. Although this species occurs at Pinang in numbers at all seasons, it is never very plentiful.

(3639) *Sillago domina*, Cuv. and Val. which is very numerous at Pondicherry, Madras, and indeed as far north as the mouths of the Ganges, appears to be unknown at Pinang and Singapore.

Genus URANOSCOPUS, *Grónov.* 1754. Head large, depressed, rough; eyes and mouth vertical; lower part of preopercle crenate; shoulder with a strong spine; branchiostegous rays six; dorsal fins two, or both united into one; vent central.

(3640) *Uranoscopus cognatus*, Cantor. Head above and back pale brownish green, cheeks, sides and abdomen silvery, minutely dotted with black; jaws blackish; anterior dorsal fin black, near the base clouded whitish; posterior dorsal whitish, minutely dotted with black between the branches, and along the upper half of the rays; caudal bright gamboge; the membrane between the branched part of the rays white, and along the branches minutely dotted with black; anal and ventral fins white; pectorals white, minutely dotted with black, the apex of each ray scarlet. Iris pale golden green, blackish towards the orbit; pupil very minute, like a brilliant black point. D 3—1/15, C 12½, A 14, V 1/5, P 18, Br. VI. Inhabits *Sea of Pinang*. Total length, 5⅛ inch. Except in colours and in the number of fin-rays, this species so closely resembles *Uranoscopus scaber*, Linné, that it will be sufficient to point out the differences. The eyes are vertical, and the very small circular pupils are directed upwards, but the level of the orbit is somewhat sloping, the outer margin being lower than the inner; the orbit itself is oval, its greatest diameter, equalling the distance between the eyes across the vertex, is oblique slightly diverging forward from the medial line of the vertex. The length of the head from the lower jaw to the nape of the neck slightly exceeds ⅓ of the total, but measured to the apex of the opercle it slightly exceeds ¼ of the total length. The anterior process of the infraorbital bone covering the maxillary, terminates in an obliquely downward pointed spine, which is rugged or shagreened like the rest of the covering of the head. The lips have a series of close fleshy papillæ. The upper maxillary teeth are in two series, of which the outer is the more minute, those in the centre of the inner series are stronger than the rest; the lower jaw has on each side four or five long, distant, recurved teeth; on the symphysis they are closer, in two series, of which the inner contains the longer teeth. The four spines of the lower margin of the preopercle are placed by a central interval in two pairs: an anterior, and a posterior. Of the four indentations or shallow depressions of the ascending margin, the uppermost is the smallest. The lower part of the posterior margin of the opercle has a finely toothed appearance, produced by some oblique ridges terminating there. The strong vertical spine of the subopercle is on a level with the four spines of the preopercle. In front of the anterior of the latter is a small broad triangular spine. Between and beneath the angles of the lower jaw appear on each side three forward pointed spines, of which the superior, the longest, is directed obliquely downward, and touches the opposite one; the other two pairs are vertical, the posterior being the shorter. The scapular spines are small, but distinct; the humeral spine is very strong, triangular and longitudinally furrowed like a bayonet; its length is little less than ½ of the pectoral fin, or equal the upper margin of the opercle. The length of the pectorals equals ⅕ of the total; the inferior eight rays are thicker than the rest. The ventrals are less than ⅒ of the total. The anterior dorsal is triangular, its height less than ⅕ of the vertical diameter of the body, which is contained about 4½ times in the total length. The posterior dorsal commences with a short, thin spine, which so closely reclines towards the back, that it easily may escape observation; the first three rays are undivided, gradually increasing in length; the fourth is the longest, about ⅔ of the vertical diameter of the body; the fifth and sixth are shorter; the rest nearly equal about ½ of the length of the fourth ray. The rays of the anal fin are somewhat shorter, but not thicker than those of the posterior dorsal The precise shape of the fin could not be ascertained, as it happened to be somewhat mutilated in the only individual observed. The naked space behind the posterior dorsal and that behind the anal, is a little more than 1½ of the total length; the caudal is about ⅕. The space on the back between the lateral lines is covered with scales like those of the rest of the back, sides, and the posterior half of the abdomen; the anterior half of the latter and the chest are apparently naked. Of the Asiatic species, described by M. M. Cuvier and Valenciennes, the present nearest approaches *U. marmoratus*, which differs in colours, in the smaller humeral spine, in having five preopercular teeth, the space between the lateral lines naked, and the skull is shagreened but on the posterior part only. The capacious, leathery stomach contained remains of minute *Crustacea* and mud; its length (4⅛ inch.) a little less than ⅛ of the total; that of the intestinal canal 4⅛ inch. There are eight cæcopyloric appendages. The gall-bladder excessively large, elongated, bottle shaped, in length nearly equalling the stomach, transparent pale greenish. The fishermen of Pinang asserted this species to be of very rare occurrence and to grow but little larger.

Genus SPHYRÆNA, *Artedi.* 1738. Body elongated with two separated dorsal fins, head oblong, with the lower jaw projecting in a point beyond the upper; some of the teeth large, pointed, trenchant; preopercle not toothed; opercle without spines; branchial rays seven; cæcopyloric appendages numerous.

(3641) *Sphyræna jello*, Cuv. and Val.

Syn. Russell CLXXIV. Jellow.
Sphyræna jello, Cuv. and Val. III. p. 349.
Sphyræna jello. Belanger, Voy. Zool. p. 346, Pl. I. Fig. 1.
Sphyræna jello, Ruppell, N. W. Fische, p. 98.
? Sphyræna jello, Bleeker: Verh Batav. Gen. XXII. 24, 56, 4.

Head above and back dark greyish green, forming on the upper part of the sides a festooned band, intersecting the lateral line; cheeks and sides pale silvery, abdomen white; ventral fins whitish, the other fins pale yellowish; dorsals, caudal and pectorals minutely dotted with black near the margins. Iris pale golden, blackish near the orbit. D 5—1/9, C 17$\frac{8}{8}$, A 1/8 or 9, V 1/5, P 13 or 14, Br. VII. Inhabits *Sea of Pinang, Singapore*, Bay of Bengal, Red Sea. Total length, 1 foot 6 inch. The length of the head is 3$\frac{1}{2}$ of the total, taken from the symphysis of the lower jaw to the centre of a vertical line cutting the lobes of the caudal; but taken from the symphysis to the centre of the caudal itself, the head is 3$\frac{1}{3}$ of the total. The horizontal diameter of the oval eye is $\frac{1}{5}$ of the length of the head. The opercle terminates in two small, flat, membranous points. At Pinang a few at the time occur at all seasons. The length given is the common, but according to Russell an individual of 4 feet has been observed. In one examined the stomach contained remains of *Trichiurus*. The air vessel is long, cylindrical.

(3642) *Sphyræna obtusata*, Cuv. and Val.

Syn. ? Sphyræna chinensis, Lacepede, Pl. 10, Fig. 2.
Sphyræna obtusata, Cuv, and Val. III. 350.
? Sphyræna obtusata, Bleeker: Verh. Batav. Gen. XXII. 24, 56, 4

Head above and back dark greyish green, paler on the upper part of the sides, and clouded beneath the lateral line, cheeks and the rest of the sides pale silvery; abdomen white; pectorals and ventrals whitish, the other fins and the iris like *S. jello*. D 5—1/9, C 17$\frac{8}{8}$, A 1/9, V 1/5, P 13, Br. VII. Inhabits *Sea of Pinang, Singapore*, Port Jackson, Isle of France, Malabar, Pondicherry, Batavia, Surabaya. Total length: 2 feet 6 inch. The length of the head from the symphysis to the centre of the posterior caudal margin is about $\frac{1}{3}$ of the total lengh. The horizontal diameter of the oval eye is $\frac{1}{4}$ of the length of the head: the eye consequently appears comparatively larger than in *S. jello*. The opercle terminates in a single flat, membranous point; the preopercle is not rounded, but almost rectangular: the sympysis of the lower jaw is obtuse, and less prominent than in *S. jello*. There are but three longer teeth [illegible] the second, third and [illegible] "its membranous front on each side of the palatals; [illegible]oval. It occupies uniformly small. The ventral fins terminating [illegible]ated opposite the anterior dorsal, at the termination of the pectorals, but in front of the anterior dorsal opposite the posterior half of the pectorals. The caudal fin is less deeply cleft than in *S. jello*. At Pinang a few individuals occur at all seasons.

Genus, POLYNEMUS, *Gronov.* 1754. (Pentanemus, *Artedi.*) Head compressed, covered with scales; muzzle obtuse, prominent; branchiostegous rays 7; pectoral fins with distinct appendages.

Polynemus tetradactylus, Bleeker: Verh. Batav. Gen. XXII. 24 57.
Ikan Salangan, 'Sinanghi,' or 'Salanghi' of the Malays.

Head silvery; back and sides silvery green; the latter beneath the lateral line, silvery; abdomen white; pectoral, ventral and anal fins gamboge or pale orange; dorsals and caudal greyish minutely dotted with black, their margins broad blackish; filaments white; iris silvery, metallic green at the upper part of the orbit. D 8 or 9—1/14 or 15, C 17$\frac{8}{8}$, A 3 or 4/15 or 16, V 1/5, P 17, Filaments 4, Br. VII. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula, Lancavy*, Bay of Bengal, Gangetic estuaries; Australia, China, Bantam, Batavia, Tjilatjap, Samarang, Surabaya, Bangkallang. Total length: 4 feet. It is highly valued as an article of food, its flavour being compared with that of salmon. In the Straits of Malacca single individuals occur at all seasons, but it is there not so numerous as it is in the Bay of Bengal, and the Gangetic estuaries nor of such gigantic dimensions as Buchanan Hamilton describes it to attain in the latter locality. Some individuals, which in 1837 were observed in the Bay of Bengal, and by the native fishermen denominated *Salliah* or *Soccolia*, I was induced to consider as belonging to a distinct, although closely allied species, *(P. Salliah)* as they all agreed in presenting one dorsal, and two anal-spines more than were attributed to *P.*

tetradactylus. The following is the number of fin-rays given by the different describers:

Russell:	D 8—1/14, C 22? A 1/16, V 1/5 P 17.
Buchanan:	D 8—1/14, C 15+, A 2/15, V 1/5 P 17.
Cuv. and Val.:	D 8—1/15, C 17, A 1/16, V 1/5 P 17.

The first anal spine is very minute, and as well as the succeeding one or two almost hid by scales, particularly in larger individuals. Although the figure of this species in Buchanan Hamilton's duplicate drawings represents the anal fin with *four spines* and fifteen rays, his description gives but 2/15. The length of the filaments is liable to individual variation, and in the adult they are comparatively shorter than in the young. Normally the two posterior are the longest, equalling the length of the head; the first is but $\frac{2}{3}$ of the fourth. The ascending margin of the preopercle is very finely toothed, but the lowest tooth is conspicuously larger than the rest. The lateral line is nearly straight from its posterior half. From the base of the caudal it continues sloping a little downwards on the lower half of the fin, and divides in two or three horizontal, branches, which reach the margin of the fin. A little behind the place where the cystic and hepatic ducts jointly enter the duodenum, the latter sends forth three branches which again terminate in innumerable cœcopyloric appendages. This species, as first observed by M.M. Cuvier and Valenciennes, has no air vessel.

Polynemus plebeius, Bleeker, Verh. Batav. Gen. XXII. 25, 58. (*Excl. Syn. P. sele.*)

Head above and back greenish grey, or pale bluish silvery; sides pale silvery; abdomen white; fins whitish grey, minutely dotted with black; dorsals, caudal and pectorals with pale blackish margins. Iris silvery, metallic green at the upper part of the orbit. Filaments white. D 8—1/13 or 14, C $17\frac{3}{3}$, A 3/12 or 13, V 1/5, P 13 or 14, Filaments 5, Br. VII. Inhabits *Sea of Pinang*, Otaheiti, Isle of Tanna, Isle of France, Coast and estuaries of Coromandel, Japan, Polynesia, Batavia, Samarang, Surabaya, Sampang, Madura. Total length, 1 foot: The length of the head is $\frac{1}{4}$ of that of the body, measured from the muzzle to the centre of the caudal margin; but in the length taken from the muzzle to the centre of a vertical line cutting the lobes of the caudal, that of the head is contained $4\frac{1}{2}$ or 5 times according to the individually varying length of the caudal fin. The horizontal diameter of the eye is contained $3\frac{1}{3}$ times in the length of the head. The preopercle is more finely toothed than it is in *P. traductylus*: the lowest tooth is longer than the rest. The anterior dorsal fin commences opposite the posterior extremity of the opercle, the extent of the base being $\frac{2}{3}$ of the length of the third spine. The posterior dorsal commences a little in front of the anal, the extent of its base equalling the length of the third dorsal spine. The distance between the two fins exceeds by $\frac{1}{4}$ the extent of the base of the anterior dorsal, while it is but little less than the extent of the base of posterior dorsal. The two or three posterior filaments are longer than the pectoral fin. The lateral line is nearly straight towards the root of the caudal, over which it extends in a downward slightly oblique direction to a little beneath the cleft. The caudal fin is more or less deeply cleft: the upper lobe in some individuals is longer than the lower; both are pointed, but neither terminates in a filament. In a fresh state no longitudinal dark lines appear on the body, but in the young three or four of the scales of the lateral line near its origin, are densely dotted with black, so as to appear like a blackish serrated spot. The individuals observed at Pinang differ from the description of *P. plebeius* by M. M. Cuvier and Valenciennes in having three or four pectoral rays less, anal three anal spines instead of two, but the first of the three is so short, and so hid by the scales, that it easily may escape observation. In other external characters there is no difference, and they also agree in presenting a great number of cœcopyloric appendages, and in having an elongated narrow air-vessel, *without appendages*. At Pinang this species is of rare occurrence, and of the few observed, the largest measured but one foot in length. Its value as a fish yielding isinglass requires to be ascertained in localities which it frequents, and where it attains its full size: 4 feet.

Ikan Kurow of the Malays.

Head above dark bluish, or greyish, lighter greyish on the sides ; abdomen white ; opercle bluish silvery with a blackish spot on the upper half ; the body everywhere more or less densely dotted with black ; pectorals black, the other fins greyish or bluish white, dotted with black, often so densely as to give the dorsals, ventrals, the anal and the caudal a blackish appearance ; the filaments of the caudal lobes black ; the anterior half of the pectoral filaments white, the posterior blackish. Iris silvery. D 8 1/13 or 14, C 17½, A 3/11 or 12, V 1/5, P 13 or 14, Filaments 5, Br, VII. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula*, Pondicherry, Madras, Vizagapatam, estuaries of the Ganges, Surabaya. Total length : 3 feet. The length of the head is contained about 3½ times in that of the body, measured from the muzzle to the centre of the caudal margin. The horizontal diameter of the eye is about ⅓ of the length of the head. The ascending margin of the preopercle is more strongly toothed than in *P. plebeius*, the lowest tooth being the longest. The anterior dorsal commences behind the termination of the opercle, opposite the second half of the pectoral fin, the extent of its base being nearly equal to the length of the fourth spine. The posterior dorsal commences considerably in front of the anal, the extent of its base equalling the third dorsal spine. The distance between the two fins is nearly equal the base of the anterior dorsal. The two or three posterior or upper filaments are longer than the pectoral fins. In the young they are comparatively larger : one or two reaching to the anal fin. The lobes of the caudal fin are unequal, the lower being, generally, but not always, the longer. The length of the caudal filaments is greater in the very young, in which the lower almost equals the length of the body. The lateral line proceeds nearly straight to the centre of the root of the caudal, from whence it is continued obliquely downwards over the lower lobe. The most striking character by which this species at once may be distinguished from *P. plebeius* is the structure of the air vessel, of which M.M. Cuvier and Valenciennes observe : " its membrane is silvery, thick, the general form oval. It occupies the whole length of the stomach, terminating behind in a very sharp point, which penetrates the thick of the tail over the first interspinal of the anal. It adheres to the third, fourth, fifth, sixth and seventh abdominal vertebræ. From both sides towards the ventral surface, proceed twenty eight to thirty-five appendages, which, with the exception of the three last ones, have two roots, but terminate in a single sharp point. Above each of these, towards the dorsal surface, appear one or two others. All the appendages penetrate the thick of the muscles, and are slightly directed towards the back of the fish." (Hist. Nat. des Poiss. T. III. p. 285.) Also this species is distinguished by a very great number of cœcopyloric appendages, divided in two portions : one containing the longer and larger, adheres to the stomach, the other to the intestine. At Pinang single individuals occur at all seasons, but numbers are taken from June to August. The weight is commonly from 4 to 6 lb, seldom exceeding 20. The air-vessel of a good-sized fish when dried, and ready for the market in China, weighs upwards of 2 ounces, is considered very good isinglass, and fetches 25 to 30 Spanish Dollars per Pikul. The fish itself is valued as an article of food, although less so than *P. tetradactylus*. As to the *Synonymy of Polynemus indicus*, it may be stated that *Russell*, the first describer of this species, has also published the only correct figure, No. CLXXXIV. His formula of the fin-rays is : D 8—1/14, C 20, A, 3/13, V 1/5, P 17. *Shaw*, quoting the description of Russell, named the species *P. indicus*, which denomination, however objectionable, claims priority. *Buchanan Hamilton* described this species as *P. sele*, which he observed strongly resembles the description of Russell's No. CLXXXIV. but he strangely misunderstood Russell's formula of the anal fin, so as to believe that it expressed "two fins behind the vent." and concluded that *P. sele* must be identical with *P. plebeius*. As to the identity of *P. sele*, there can be no doubt, as there exists in the duplicate series of Buchanan's drawings, a coloured figure, which although not quite correct, it is but justice to add, is far superior to the two copies of the drawing published by Mr. McClelland. *M.M. Cuvier and Valenciennes*, who could judge of *P. sele* but by the in part erroneous description of Buchanan, admit on his authority its identity with *P. sele*, not however without expressing a doubt. *Mr. McClelland*, in *Journ. As. Soc.* Vol. VIII. p, 203, published a description of "*Polynemus sele*," and a copy of the drawing in Buchanan's duplicate series. The fin-rays are given as follows : D 7—14. C 20 (?), A 12 or 13, T 6, P. 13. The air vessel is described as "a large spindle-shaped organ about half the length of the fish, thick in the middle and tapering towards the extremities, where it ends in front by two, and behind by a single tendenous cord ; similar small tendenous attachments, about twenty-two in number, connect it on either side to

the upper and lateral parts of the abdominal cavity." The characteristic form of this organ was first observed by M.M. Cuvier and Valenciennes, and a reference to their description of *P. uronemus* (*P. indicus*, Shaw) might have proved the identity of that and *P. sele*. Notwithstanding the distinctive character presented by the air vessel of this species, Mr. McClelland, in an editorial "On the East Indian Isinglass," (Cal. 'Journ. of Nat. Hist. Vol, III. p. 179) asserts, "*Polynemus plebeius*, *P. lineatus* and *P. sele* are names which have been proposed by different authors for the same species," and suggests as a more appropriate name a new one of his own: *P. gelatinosus*. Mr. McClelland quotes a translation of the description of *Polynemus plebeius*, by M.M. Cuvier and Valenciennes, in which it is distinctly observed, that this species "has a very large swimming bladder, thin, and without appendages." Yet Mr. McClelland, by way of illustrating the description of this species *without appendages to the air vessel*, has republished a copy of Buchanan's drawing of *P. sele* (l. c. Pl. VI.), the air-vessel of which Mr. McClelland himself had previously (Journ. As. Soc. Vol. VIII. l. c.) described as presenting on either side about "*twenty-two tendenous attachments*." Thus, in a paper avowedly written to call attention to the air-vessel (the isinglass) of one species, and to instruct the reader how to distinguish this species from others, not only are two species confounded, but the confusion is increased by publishing a description of a species, totally distinct from the one intended to be described, and by illustrating that description by means of a figure of another different species.

(3646) *Polynemus sextarius*, Bloch, Schneider.

Syn. Polynemus sextarius, Bl. Schn. 18, Pl. 4.
Polynemus sextarius, Cuv. and Val. III. 388.
Polynemus sextarius, Bleeker, Berh. Batav. Gen. XXII. 59.

Young. Head above and back yellowish green, lighter on the sides; abdomen pale silvery; opercle silvery with a blackish spot; another black spot, nearer the back, between the head and the anterior dorsal; fin-membranes greyish white, minutely dotted with black towards their free margins; filaments white. Iris silvery, black towards the upper part. D 8—1/12, C 17$\frac{10}{10}$, A 3/12, V 1/5, P 14, Filaments 6, Br. VII. Inhabits *Sea of Pinang*, Tranquebar, Coromandel, Batavia. Total length: 4 inch. The length of the head is $\frac{1}{4}$ of the total measured from the muzzle to the centre of the posterior caudal margin. The orbit is oval obliquely situated: its greatest diameter, parallel to the upper jaw, is $\frac{1}{3}$ of the length of the head. The ascending margin of the preopercle is finely toothed, the lowest tooth longer than the rest. The length of the third dorsal spine, the longest, is little less than the greatest vertical diameter of the body; the length of the second dorsal spine equals the extent of the base of the anterior dorsal fin. In height the fin itself slightly exceeds the posterior. The lateral line is nearly straight; from the root of the caudal it deviates a little downwards proceeding to the posterior margin of the lower lobe. The filament nearest the pectoral is a little longer than the rest, its length nearly equalling that of the head; the other five are nearly equal. A solitary individual occurred at Pinang in 1843. As observed by M.M. Cuvier and Valenciennes, the air-vessel is excessively small, pointed at both extremities, of the shape and size of a grain of oats.

(3647) *Polynemus hexanemus*, Cuv. and Val.

Syn. Polynemus hexanemus, Cuv. and Val. III. 389.
Polynemus hexanemus, Bleeker: Verh. Batav. Gen. XXII. 25, 59.

Head above and back yellowish green, abdomen pale silvery; fin-membranes pale yellow minutely dotted with black, particularly the pectoral fins which have a black appearance; filaments white. Iris silvery, dotted with black towards the upper orbital margin. D 8—1/12, C 17$\frac{5}{5}$, A 3/11, V 1/5, P 13, Filaments 6, Br. VII. Inhabits *Sea of Penang*, Batavia, Samarang, Pasuruan. Total length: 4 inch. The length of the head is $\frac{1}{4}$ of the total, measured from the muzzle to the centre of the posterior caudal margin. The orbit is oval, situated as in *P. sextarius*: its greatest diameter is contained 3$\frac{1}{2}$ times in the length of the head, in consequence of which the eye appears comparatively smaller than in the preceding species. The ascending margin of the preopercle is finely toothed, the lowest tooth being stronger than the rest. The first dorsal spine is minute and almost hid by the scales. The length of the third and fourth dorsal spines, the longest, are but about $\frac{3}{4}$ of the greatest vertical diameter of the body. The length of the second dorsal spine is a little less than the extent of the base of the anterior dorsal fin. In height the fin itself is somewhat less than the posterior, the reverse of which is the case in *P. sextarius*. At the root of the caudal fin the hitherto straight lateral line deviates a little downwards, and then again continues straight towards the centre of the margin. The scales of the body have a short raised line in the centre, producing series of continued lines parallel to the lateral. The second, third and fourth filaments from the pectoral fin, are the largest, greatly exceeding the length of the head, almost extending to the anal fin; the rest are nearly equal, somewhat shorter. From the description of M.M. Cuvier and Valenciennes, founded upon a drawing by M.M. Kuhl and Van Hasselt, the present principally differs in the comparative shortness of the 2d, 3d, and 4th pectoral filaments. Although not extending to the caudal fin, they are the longest, and thus retain the re-

lative dimensions. As these organs are liable to individual variations in all the other species, there appears no reason to doubt the identity of the present and *P. hexanemus*. From *P. xanthonemus*, Cuv. and Val. the present differs in the lineated scales, and in the length of the caudal lobes, being more than ⅓ of the total. A single individual was observed at Pinang in 1844.

(3648) *Polynemus heptadactylus*, Cuv. & Val.

Syn. Polynemus heptadactylus, Cuv. and Val. III. 390.
Polynemus heptadactylus, Bleeker: Verh. Batav. Gen. XXII. 25, 60.

Head above and back yellowish green; sides beneath the lateral line and abdomen pale silvery; fin-membranes pale yellow, minutely dotted with black, particularly the pectoral fins which have a black appearance; filaments white; the points of the four superior, nearest the pectorals, bright yellow. Iris silvery, blackish towards the upper margin of the orbit. D 8 —1/12, C 17$\frac{1}{10}$, A 3/11, V 1/5, P 13, Filaments 7, Br. VII. Inhabits *Sea of Pinang*, Batavia, Cheribon, Samarang. Total length: 4$\frac{1}{8}$ inches. In colours, general outline, and relative proportions this species so greatly resembles *P. hexanemus* that no difference can be assigned, but the additional seventh filament. The straight lateral line deviates slightly downward at the root of the caudal; on the middle of the fin it divides in two parallel branches, which terminate in the centre of the posterior margin. The scales have a raised central line, forming series of continued lines, parallel to the lateral line. The two filaments nearest the pectoral fins and the seventh are equal, shorter than the other four which extend to the anal fin. The ascending margin of the preopercle is toothed as in *P. hexanemus*. According to M.M. Cuvier and Valenciennes the present in forms and colours so closely resembles the American species: *P. plumieri*, (Lacep), *P. virginicus*, Linne?—*P. paradisæus*, Bloch.—*Polydactylus plumieri*, Lacep.—*P. americanus*, Cuv. and Val. that they can assign no distinguishing characters.—Nevertheless, the two are specifically distinct. The American species is described as having a large, thin air-vessel, without appendages, and numerous small cœca. *P. heptadactylus* has but four rather large cœcopyloric appendages, and no air-vessel. At Pinang it is of very rare occurrence. Of three individuals observed, none exceeded the length given.

GEN. MULLUS, *Linne* 1766.

Sub. Gen.—HYPENEUS, *Cuvier*, 1829.

Resembling *Mullus*, but with teeth in both jaws; some with velvety teeth on the palate and vomer; opercle generally terminating in a sharp point.

1. *With velvety teeth in both jaws, on the palate and vomer.*

(3649) *Hypeneus vittatus*, (Forskal) Var.? *Mullus vittatus*, Forskal Fauna Arab. 31, No. 28.—*Mullus vittatus*, Linne: Syst. 1341.—Lacepede, III. Pl. 14, Fig. 1.—*Mullus barbatus*, Bloch-Schneider, 79.—Russell CLVIII. *Bandi Goolivinda.*—*Mullus bandi*, Shaw IV. 615.—*Mullus vittatus*, Shaw IV. 616, Pl. 69.—*Upeneus vittatus*, Cuv. and Val. III. 448. *Young.* Head above and back pale bronze, with a whitish band above the lateral line, along which the ground colour appears like a bluish line; sides and abdomen pale silvery; a yellow longitudinal band from the posterior angle of the eye, at first beneath the lateral line, which it intersects a little in front of the caudal fin; a second paler yellow band from the pectoral to the root of the caudal; cheeks and opercles silvery; opercle with a pale crimson spot continued obliquely down the preopercle; a second smaller spot over the point of the opercle and the root of the pectoral; dorsals with two or three transversal blackish back; caudal pale yellowish with a broad blackish margin; pectorals white; rays of anal, ventrals and the gular filaments pale yellow. Iris pale golden. *Older.* Head above Indian red, continued on the back; cheeks and opercles silvery rose-coloured; caudal pale orange with a broad blackish margin. Iris golden crimson. D 8 —1/8, C 15$\frac{1}{4}$, A 1/6 or 7, V 1/5, P 15 or 16, Br. IV. Inhabits *Sea of Pinang*, Total length: 5 inch. M.M. Cuvier and Valenciennes count 7 spines in the anterior dorsal; Russell gives 8, and correctly figures the first as being very small. Single small individuals occur at Pinang at all seasons.

2. *With velvety teeth in both jaws; palate toothless.*

(3650) *Hypeneus flavolineatus*, (Lacepede) Var. *Mullus flavolineatus*, Lacepede III. 406.—*Mullus aureo-vittatus* Shaw IV. 618.—*Upeneus flavolineatus*, Cuvier and Valenciennes III. 456. Head above and back pale bluish brown or bronze; cheeks, sides and abdomen pale greenish silvery; from the lower part of the orbit a vertical crimson streak; opercle and the root of the pectorals crimson; on each side beneath the lateral line a broad longitudinal orange, or rust-coloured band, intersecting the lateral line at the commencement of the posterior dorsal, and terminating above it at the root of the caudal; fins pale yellow; dorsals and caudal each with three or four oblique waved reddish bands; lower part of anal and ventrals pale reddish; gular filaments yellow. Iris golden. D 7 or 8—9, C 15$\frac{1}{4}$, A 7, V 1/5, P 14 or 15, Br. IV. Inhabits *Sea of Pinang*. Total length: 5$\frac{1}{4}$ inch. M. M. Cuvier and Valenciennes count 7—9 in the dorsal fins; in some individuals however, a very minute spine precedes the longest. Those observed at Pinang appear principally to differ from *H. flavolineatus* in having waved reddish bands on the dorsals and caudal fins. It must

however be observed that these bands become totally obliterated shortly after death. The lateral band remains, but it changes to blackish. In other characters this fish agrees with the description of *H. flavolineatus*. The length of the head is contained 4¼ times in the total, measured to the centre of the caudal margin; the greatest vertical diameter of the body is 5½ of the total: the eye occupies about the third fourth from the muzzle, its diameter equalling ¼ of the length of the head. The distance between the two dorsals equals the extent of the base of the posterior, but is somewhat less than that of the anterior. The ramifications of the lateral line consist of 5 or 6 branches on each scale, of which three or four are directed obliquely upwards, one downwards. The root of the scales has four or five crenulations. The filaments are rather thick, fleshy, slightly exceeding the commissure of the gill-openings. Single individuals occur at all seasons at Pinang.

Fam. CATAPHRACTOID.E.

Genus Platycephalus, (*Bloch, Schneider* 1801) *Cuv. and Val.* Head much depressed with trenchant edges, armed with spines, body covered with scales; ventral fins five-rayed, widely separated from each other, owing to the lengthened and flattened shape of the pelvic bones; palate with sharp teeth; branchiostegous rays 7.

(3651) *Platycephalus insidiator* (Forskal).

Platycephalus insidiator. Richardson Rep. 1845, 216.
Platycephalus insidiator, Bleeker, Verh. Batav. Gen. XXII. 6.

Head above and back greenish or brownish grey with a few smaller and larger dark brown scattered spots; sides, from a little below the lateral line, and abdomen white; fin membrane of the caudal white, orange or yellow at the base and along the rays; the base indistinctly spotted with brown; the upper and lower angle black, between both three longitudinal, somewhat oblique black bands, liable to individual variations, the membranes of the other fins whitish, transparent; the dorsal, ventral and pectoral rays more or less distinctly annulated with brown. Iris pale golden green; pupil black, heart-shaped by a pointed lobe descending from the upper margin of the iris. D 1—8—1—13, C 15⅔, A 13, V 1/5, P. 18 or 19, Br. VII. Inhabits *Sea of Pinang*, Sea of Madagascar, Red Sea, Moluccas, Seas of China and Japan, Batavia, Bay of Bengal, estuaries of the Ganges. Total length: 1 ft. 6 inch. M.M. Cuvier and Valenciennes count 8 spines in the anterior dorsal fin; at a short distance, however, in front of the first of these eight, is a very small isolated reclining spine, and in the space between the eight spine, and the first ray of the posterior dorsal, slightly nearer the latter than it is the former, is another very minute isolated reclining spine, which thus make the whole number of spines 10 instead of 8. The first and the tenth spines are so minute, and in the living fish so hid in the scales, that they easily escape notice. Russell, indeed, in Pl. XLVI. correctly gives the tenth spine, and his description counts 9—13 inch the dorsal fins. This as well as the following species *Platycephalus* is occasionally taken in the fishing stakes placed along the coasts; they are all capable of sustaining life some little time out of water. They are eaten by the natives.

(3652) *Platycephalus clavulatus*, Cantor. (*Young?*)—Head above, opercles, back and sides pale reddish brown; beneath and behind the posterior dorsal fin some large patches of a lighter brown; along the anterior half of the back some distant brown dots; along the lateral line a more regular series of distant brown dots; abdomen and sides, from a little below the lateral line, white; from behind the ventral fins minutely dotted with brown; cheeks whitish, minutely dotted with brown, and with two short vertical brown streaks beneath the orbit; membrane of anterior dorsal minutely dotted with brown; the upper half so closely so, as to acquire a blackish appearance; posterior dorsal whitish, each ray with one or two brown; dots at the upper part; caudal membrane whitish, minutely dotted with brown; at the root an indistinct semicircular brown band, near the margin some irregular brown spots, which near the lower part are confluent, forming an oblique band; anal whitish; ventrals and pectorals minutely and so closely dotted with brown, as to have a blackish appearance; the upper six or seven pectoral rays white, annulated with brown, the 19th and 30th ray, white. Iris pale greenish golden, minutely dotted with brown; pupil heart-shaped. D 8—11, C, 15⅔, A 11, V 1/5, P 20, Br. VII. Inhabits *Sea of Pinang*, Total length 5⅞ inch. The length of the head is contained nearly 3½ times in the total; the eye occupies the second

fourth part from the muzzle; the distance between both eyes is less than one half of the vertical diameter of the eye. The nasal bone is rough, but without spines. At the commencement of the supraorbital crest is a reclining spine, on the posterior half three smaller, and on its continuation along the sides of the occiput are two distant spines: from the orbit along the upper margins of the opercles proceed 5 small gradually backwards increasing spines; the opercle has two backwards diverging linear crests without spines. On the middle of the anterior infraorbital bone is a small reclining spine: on the posterior two distant larger, from whence proceeds a raised linear crest, terminating in the upper angular spine of the preopercle. The latter spine extends to the margin of the opercle, its length exceeding three times that of the smaller, lower spine. The angle of the mouth is situated opposite the anterior angle of the orbit. The dentition resembles that of *Platycephalus insidiator*: the upper maxillary velvety teeth form a very narrow band, which is considerably widened on the intermaxillary bones, where the posterior series has on each side three teeth longer than the rest. The lateral line is nearly straight, less approaching the back than in *P. insidiator*; at its commencement, as far as the middle of the anterior dorsal, every other scale has a minute reclining spine; the rest of the lateral line, though raised and distinct, appears to be spineless. The present species of which a single, apparently young, individual was observed at Pinang in 1843, appears to be closely allied to *Platycephalus scaber*, (Linne).

(3653) *Platycephalus carbunculus*, Cuv. and Val.

Syn. Platycephalus carbunculus, Cuv. and Val. IX. 461.

Ground colour greenish buff; head, cheeks, back and sides spotted with blackish brown, forming three short vertical bands on the sides of the head beneath the orbit, and three larger irregular bands on the sides of the body; throat and abdomen white; anterior dorsal fin white, upper half pale blackish, marbled with white veins; posterior dorsal, caudal, ventrals and pectorals white; the rays annulated with pale black; posterior half of caudal pale blackish with two or three waved vertical white lines; anal white, each ray with one or two brown dots near the extremity. Iris pale greenish golden, spotted with brown; pupil black, heart-shaped. D 9—11 or 12. C 11$\frac{1}{3}$, A 12, V 1/5, P, 19, Br. VII. Inhabits *Sea and estuaries of Pinang*, Bombay. Total length: 6$\frac{1}{4}$ inch. The length of the head is $\frac{1}{3}$ of the distance from the muzzle to the root of the caudal; the latter is $\frac{1}{5}$ of that distance. The breadth of the head in front of the eyes exceeds by $\frac{1}{3}$ the distance from the muzzle to the anterior part of the orbit. The raised supraorbital crest is strongly serrated, leaving the upper part of the skull like a narrow furrow, the breadth of which is scarcely $\frac{1}{4}$ of the vertical diameter of the eye. The upper maxillary teeth form a much broader band than in either *P. insidiator* or *P. clavulatus*, and it is but little widened on the intermaxillary bones, on which the teeth are of uniform length, velvety like the rest. The number of spines of the head renders this species conspicuous. It occurs, although not numerously, at all seasons at Pinang, and it is eaten by the natives.

Genus SCORPÆNA, (*Artedi*) Linne 1748. Head large, spinous, filamentous, scaleless, compressed; eyes placed near each other; teeth in the jaws, vomer, and palate; dorsal fin single, anterior part spinous; branchiostegous rays seven.

(3654) *Scorpæna picta*, Kuhl and Van Hasselt.

Syn. Scorpæna picta, Cuv. and Val. IV. 321.
Scorpæna picta, Bleeker: Verh. Batav. Gen. XXII. 4.

Head greenish olive, largely spotted with black, radiating round the orbit; ground colour of body and fins pale greenish or brownish buff, on the back and sides above the lateral line largely and irregularly marbled with black, which beneath the anterior part of the soft dorsal is continued vertically towards the abdomen; the latter and the rest of the sides irregularly spotted with brownish black; spines and fin rays, except the ventral, greenish buff, annulated with brownish black; membranes of dorsal, caudal and anal fins greenish buff; the spiny part of the dorsal largely washed with black, the rest with a broad vertical blackish spot, continued over the body, and with two smaller at the posterior margin; caudal with a vertical blackish band at the root, a second in the middle, a third at the margin; membranes of pectorals blackish brown; of anal with a black spot behind the root of the second spine, and an irregular blackish transversal band across the middle, with black spots on the margin; ventrals uniformly blackish brown. Filaments of the body black with slate grey points; the two large supraorbital ones olive, largely spotted with black. Iris golden dark olive with five broad radiating black streaks. D 12/10, C 13$\frac{2}{3}$, A 3/5, V 1/5, P 17, Br. VII. Inhabits *Sea of Pinang*, Java, Celebes. Total length: 7 inch. The length of the head is a little less than $\frac{1}{3}$ of the total; the eye occupies the second fourth from the muzzle; the angle of the mouth is situated a little in front of the eye, opposite the lowest of the anterior infraorbital spines, which latter is arched downwards, but has its point directed forwards like the two larger ones. Of the three supraorbital spines the central is the strongest: behind it appears a fleshy pointed filament, in length equalling the diameter of the orbit. Smaller filaments are scattered over the body, and a series appears above the lateral line.

The second anal spine is the strongest of all, its length equalling that of the anal fin, which is $\frac{1}{6}$ of the total length. The band of velvety teeth in the upper jaw is narrowed towards the intermaxillary bones. The reverse is the case in the lower jaw, where the band of teeth is considerably widened on the symphysis. The innermost of the lower maxillary teeth are longer than the rest. The present offers the specific characters of *S. picta* in having the lowest of the anterior infraorbital spines directed forwards, and the second anal spine excessively large; but it differs in presenting a long filament above each eye, which did not exist in the specimen described by M. M. Cuvier and Valenciennes. A single individual occurred at Pinang in 1842.

Genus PTEROIS, *Cuvier*, 1819. Differs from *Scorpæna* in the absence of palatal teeth, and in having the dorsal spines and pectoral rays excessively elongated.

(3655) *Pterois miles*, (Bennett.)

Syn. Scorpæna miles, Bennett: Ceylon, Pl. 9.
Pterois muricata, Cuv. and Val. Although this Vol bears 1829 on the title-page, the description quotes *S. miles* Bennett, in *Fishes of Ceylon*, the first edition of which appeared in 1830. However this may be, M. M. Cuvier and Valenciennes in quoting Bennett, admit the priority of his description and figure, and his specific denomination must therefore be retained. IV. 363.
Macrochyrus miles. *Macrochyrus*, Swainson, founded on *Scorpæna miles*, Bennett, is characterised as having "the pectoral fins only one-third as long as the body, and the mouth subvertical." Both characters however, are incorrect; the pectorals in every stage of growth much exceed one-third of the body (total length?), and the mouth opens obliquely as in *Pterois* miles. Swainson II. 264.

Adult. Ground colour of head and body, impure rose or flesh-colour, the scales edged with lighter or darker reddish brown, so as to produce a net-work; sides of the head and body with oblique and vertical scarlet bands, the number and breadth varying individually: across the hind-head two or three such, and between the eyes a longitudinal scarlet band; behind the point of the opercle a triangular black spot; lips, throat and abdomen reddish white; dorsal spines scarlet, broadly annulated with black, or white; their membrane scarlet, in some with the pointed portion attached to each spine, black, or with a triangular black spot near the base; dorsal, caudal and anal rays and membranes scarlet; and spines scarlet, their membrane reddish back; pectoral rays scarlet, more or less annulated with black; base of the pectoral scarlet, continued over the root in the shape of three oblique bands; membrane brownish green or bronze, with a black streak along each ray; ventral spine alternately white and scarlet; membrane pale blackish green, with longitudinal series of black and milky spots between and across the rays; posterior half of the membrane black; a scarlet spot inside the root of each pectoral. Supraorbital fleshy filaments black; those of the upper jaw and preopercle white with scarlet points. Iris silvery white, with four or five scarlet or reddish back radiating bars. *Young.* Colours distributed as in the adult; the scarlet paler; pectoral fins uniformly greenish black. D 13/11, C $14\frac{3}{3}$, A 3/7, V 1/5, P 12 or 13, Br. VII. Inhabits *Sea of Pinang*, Ceylon, Red Sea, Bourbon. Total length, $9\frac{3}{8}$ inch. The length of the head is $\frac{1}{4}$ of the total, equalling that of the caudal fin; the eye occupies the third fourth from the muzzle. Besides the nasal spine, there are two or three supraorbital ones, of which the posterior is the largest; behind it proceeds the spiny temporal ridge obliquely downwards to the commencement of the lateral line, which has one or two spines. On each side of the occiput appears a very broad spine, sharp like a knifeblade, with two points. The ridge of the infraorbital bones is spiny, proceeding obliquely over the cheek towards the margin of the preopercle, from which rise three spines. The surface beneath the infraorbital ridge is uneven to the touch, but without spines. The interval between the orbits is broad equalling the transversal diameter of the eye. From the central supraorbital spine rises a pointed fleshy filament, which in the young equals one half of the vertical diameter of the eye; but in the adult it is much shorter, or absent. The most constant of the other filaments is one on the upper jaw near the angle of the mouth, and the largest are two or three on the lower margin of the preopercle. The membrane of the three or four upper pectoral rays has a very deep incision, so as to give each ray a feather-like appearance, and the points of the lowest four or five rays are free, projecting beyond the membrane. The length of the pectoral fin varies not only according to age, but also individually. In a young one the point of this fin reaches to the middle of the caudal, its length being about $\frac{2}{3}$ of the total. In one of two adults of equal length, $9\frac{3}{8}$ inches, the pectoral measures $3\frac{7}{8}$ inches, in the other $4\frac{2}{8}$ inches. In the fish as commonly seen, but a small portion of the base of the dorsal spines is connected by the membrane. In such, however, as have been examined alive, the instant they are taken out of the sea, the membrane is found continued along the posterior margin of each spine till near the point, where an elongated long flap appears, like the pendant of a lance. Out of the element the scarlet colour of the fish soon fades to a deep rose-colour, which then makes the vertical strips, on which the brown net-work appears, more con-

spicuous. The fish appears to be a heavy swimmer, and, as observed by Bennett, it never attempts to support itself in the air. At Pinang single individuals occur at all seasons. It is a very bony fish, and the flesh is said to be insipid. It preys on small *Crustacea*.

Genus PROSOPODASYS, *Cantor*. Πρόσωπον, mask; δασύς, rough. Substituted for *Apistus* Cuvier, 1829, preoccupied by *Apistis* (Ser. *Apistus*,) Hubner 1816 (*Lepidopt.*) (*Equivalent to* Apistus, *Cuvier.*) Differs from *Scorpæna* in having fewer pectoral rays and all branched, a long moveable spine on the infraorbital bone, and a similar on the preopercle.

(3656) *Prosopodasys trachinoides*, (Cuv. and Val.)

Syn. Apistus trachinoides, Cuv.and Val. IV. 401, Pl. 92. Fig. 1.
Trichosomus trachinoides. Swainson,Nat. Hist. Fish. II. 265. *Trichosomus*, in itself inadmissible, is not equivalent to *Apistus*, Cuv.
Apistus trachinoides, Richardson, Rep. 1845, 213.
Apistus trachinoides, Richardson, Voy. Samarang, Fishes, Pl. III. Fig. 3—5.
Apistus trachinoides, Bleeker, Verh. Bat. Gen. XXII, 8.

Head above and back blackish brown; sides and abdomen pale neutral tint; membrane of the dorsal fin pale bluish grey with four large oblique blackish bands, between which some oblique pale brownish lines; anal and ventrals pale bluish grey, the former with larger oblique black bands, between which some pale brownish oblique lines; the posterior half of the latter blackish; caudal yellowish white, minutely dotted with brown and with a black vertical band at the root, and one or two vertical series of black spots near the posterior margin; pectorals pale neutral tint largely spotted with blackish brown. Iris golden flesh-colour, minutely dotted with black. D 14 or 15/5. C $12\frac{3}{8}$, A 3/4, V 1/5, P 12, 13 or 14, Br. VI. Inhabits *Sea and estuaries of Pinang, Singapore*, Java, Madura, Sea of China. Total length, $3\frac{1}{8}$ inch. The fish is numerous at all seasons It is capable of living a considerable time out of its element. It is applied as manure, but not eaten.

Genus CORYTHOBATUS, *Cantor*. Κόρυς helmet; βάτος thorny. Substituted for *Minous*, Cuvier and Valenciennes 1829, pre-occupied by *Minois*, Hübner 1816 (*Lepidopt.*) *(Equivalent to* Minous. *Cuv. and Val.)* Differs principally from *Prosopodasys* (*Apistus*,) by the absence of scales, and of teeth on the palatal bones. *Minous woora*, and *M. monodactylus*, the two only species discribed by Cuvier and Valenciennes, and *M. adamsii*, Richardson: Voy. Samar. Fishes, 7, Pl. II. Fig. 4—5, have a free undivided ray beneath the pectoral fins, but *Carythobatus echinatus* has no such free ray.

(3657) *Corythobatus woora*, (Cuv. and Val.)

Syn. Russell CLX. Worrah Minoo A. [(8.)
Apistus minous, woora, Cuv.R.A. II.168.
Minous woora, Cuv. and Val. IV. 421.
Apistes Russellii, Swainson, II. 265.
Minous woora, Richardson, Rep. 1845, 213.

Head above and back brownish grey, or pale silvery grey; sides and abdomen buff or bluish white; dorsal fin buff, the margin of the spiny portion, and the upper half of the soft portion black; caudal pale yellowish white, with a vertical blackish band at the root; a second in the middle, and a third near the margin; anal and ventrals buff, their external half black; pectorals buff at the root, the rest black; the free ray white, more or less distinctly annulated with black; body and fins minutely dotted with black; filaments of lower jaw white. Iris silvery grey, minutely dotted with black. D 9 or 10/10 or 11, C $11\frac{3}{8}$, A 1/9, V 1/5, P 10 or 11—1, Br. VII. Inhabits *Sea and estuaries of Pinang, Malayan Peninsula*, Isle of France, China Seas, Vizagapatam. Total length, $3\frac{3}{8}$ inch. M.M. Cuvier and Valenciennes count 11/12 in the dorsal, Sir J. Richardson 10/11. (China Spec.) At Pinang the species is numerous, and applied as manure.

(3658) *Corythobatus echinatus*, Cantor.

Plate XIII.

Ground colour of head and body umber, pale on the sides and abdomen; fins of a darker brown than the body; on the opercles, above the lateral line and close to the anal fin some larger and smaller irregulars, light spot, edged with black; numerous similar small round spots on the fins; on the caudal three large such bordering the margin; from the root of the pectoral to the gill-opening two rose-coloured irregular bands edged with black; a similar angular sport behind the eye, and some similar bars radiating over the iris; the latter with a narrow golden circle round the pupil. D 13/11, C $11\frac{1}{2}$, A 2/8, V 1/5, P 11, Br. VI. Inhabits *Sea of Pinang*, Total length, $3\frac{7}{8}$ inch. The form of the body is broad lanceolate, with the sides highly compressed. The profile of the forehead ascends nearly vertically, from thence the back forms an arch ascending to the sixth dorsal spine, when it gradually descends towards the tail; the profile of the abdomen is a little less arched than the back. The length of the head is $3\frac{3}{8}$ of the total. The eye is placed high on the head; the vertical diameter of the orbit, slightly exceeding the horizonal, is $\frac{1}{4}$ of the length of the head; the distance of the orbit from the back, or the root of the anterior, dorsal spine is $\frac{1}{4}$ of the diameter of the orbit. The anterior, moveable, infraorbital bone carries two blunt spines of which the superior, the longer, scarcely projects beyond the middle of the orbit: both are directed backwards and downwards. The posterior infraorbital is immoveable, and has but two very minute spines.

The rounded preopercle carries four distant, flattened spines: the two lower ones are very minute, the two upper hardly extend beyond the anterior third of the opercle. The opercle terminates above in a flat membranous point, below which appear two oblique long ridges. There appears to be but a single nasal opening which is a small tube, situated in front of the lower part of the eye. The small oblique mouth scarcely reaches the level of the anterior orbital margin. The velvety teeth (Pl. XIII. Fig. 2.) are placed in both jaws on a crescent-shaped band; that of the upper is divided under the symphysis by a naked linear interval, behind which appears a minute fleshy tubercle. On the vomer appears a small crescent of velvety teeth. But the palatals are toothless. The tongue resembles that organ of *Prosopodasys trachinoides* and *Corythobatus woora:* it is moveable, fleshy, rounded, and occupies nearly the whole cavity. The greatest vertical diameter, at the root of the pectoral, equals the length of the head, the greatest thickness is $2\frac{1}{2}$ of the former diameter. The dorsal fin occupies the whole length of the back. The anterior spine rises between the anterior orbital margins: it is the longest and strongest of all, its length being about $\frac{3}{4}$ of that of the head. The succeeding spines and rays gradually decrease to the seventh ray, which is about $\frac{3}{4}$ of the length of the head. The remaining rays abruptly decrease; the eleventh, being but $\frac{1}{3}$ of the length of the head, is attached to the tail by a continuation of the dorsal membrane. All the fin rays are undivided, but jointed. The caudal is subrhomboidal or rounded, the longest, central, rays are a little shorter than the head. The extent of the anal fin slightly exceeds $\frac{1}{3}$ of the dorsal; the two spines and the seventh and eighth ray are a little shorter than the intervening rays, which are $\frac{1}{2}$ of the length of the head. The lower half of the eighth anal ray is attached to the tail by a very short continuation of the fin membrane. The anus is situated a little in front of the fin. The pectorals are elongated, rhomboidal, the central rays equalling the length of the head. The anterior ventral ray, the longest, slightly exceeds $\frac{1}{2}$ of the length of the head; the fifth is attached to the abdomen by a continuation of the fin membrane. The lateral line is a series of linear tubes, nearly following the outline of the back on the upper third of the side. The fish appears to be without scales, but it is studded with small tubercles, each surmounted by a minute, backward directed spine. The tubercles may be seen by the naked eye, but their spines may be perceived by passing a finger from the tail forward. On the back, the sides of the head and body the tubercles are fewer and more distant than on the throat and abdomen, where they are crowded. The axilla and the space covered by the pectorals is naked. A solitary individual occurred at Pinang in July 1842.

Genus SYNANCIA, *Bloch Schneider.* 1801. Differs from *Pelor* by the want of teeth on the palate and vomer, and of free rays beneath the pectoral fins.

(3659) *Synancia elongata*, Cuv. and Val.

Syn. Synancia elongata, Cuv. and Val. IV. 456.
Trachicephalus elongatus, Swainson II. 268.
Synancia elongata, Bleeker: Verh. Batav. Gen. XXII. 10.

Head, back and sides bluish brown or neutral tint, paler on the abdomen and with rose coloured lustre, everywhere minutely dotted with black, and with scattered round white spots, and white warty filaments; dorsal, caudal, anal and pectoral fins neutral tint, largely marbled with black, and with numerous white spots; ventrals neutral tint, posterior half black; points of all the rays white. Iris pale golden, dotted with black and with radiating black bars. D 10 or 11/14 or 15, C $12\frac{1}{1}$, A 2/13 or 14, V 1/5, P 14 or 15, Br VII. Inhabits *Sea of Pinang*, Java, Pondicherry. Total length: $4\frac{3}{8}$ inch M.M. Cuvier and Valenciennes count 9/15 in the dorsal fin. The length of the head is about $\frac{1}{3}$ of the total; the eye occupies the second fourth from the muzzle. On the lateral line appears a series of distant filaments, of which the anterior four are long, the rest fleshy, all with the apex divided in two. The anterior half of the line proceeds from the angle of the opercle obliquely upwards, the posterior half follows the back till the root of the caudal, where it bends obliquely downwards to the centre of the fin, terminating horizontally near the margin. This species is numerous at Pinang where, if used at all, it is with other offal applied as manure. It is capable of living a considerable time out of water.

Fam. SPAROIDÆ.

Genus. CHRYSOPHRYS, *Cuvier*, 1829. Rounded molars on the sides of the jaws, disposed in the upper jaw in at least three series; in front some conical or blunt teeth; branchiostegous rays six.

(3660) *Chrysophrys calamara*, Cuv. and Val.

Syn. Russell LXCII. Calamara.
Chrysophrys calamara, Cuv. and Val. VI. 117.

Head above blackish brown, the rest of the body silvery grey, the scales minutely dotted and edged with brown; spines, ray and fin membranes grey, minutely dotted with brown, which gives the anal and ventral membranes a blackish brown appearance. Iris silvery, minutely dotted with brown, the upper margin black. D 11/10 or 11, C $19\frac{2}{3}$, A 3/9 V 1/5 P 15, Br. VI. Inhabits *Sea of Pinang*, Java, Madras, Vizagapatam, Malabar. Total length: 10 inch. When the upper jaw is protracted the length of the head is $\frac{1}{3}$ of that of the body, the caudal fin not included; the eye borders on the profile

and occupies the centre between the protracted muzzle and the membranous point of the opercle; its diameter is little less than ⅓ of the length of the head. The second anal spine is the largest of all, its length equalling the distance from the protracted muzzle to the posterior margin of the orbit. The ventral spine equals the length of the fourth dorsal; the first soft ray terminates in a short filament. The pectoral fins when at rest, are slightly falcated, the fifth ray, the longest, reaching to the second anal spine. At Pinang this fish appears to be an occasional visitor, a few individuals occurring together at irregular intervals, and they rarely exceed 7 inches in length. The flavour is said to be good.

Genus PENTAPODUS, *Cuvier*, 1829. With three elongated pointed scales, of which one above the root of each ventral, and a single between these fins, appearing like five ventrals, or feet: mouth little cleft; body rounded, with rather hard scales, advancing farther in front than in *Dentex*. In each jaw two canines, between which sometimes two or four smaller; the rest of the teeth velvety, disposed in narrow bands.

(3661) *Pentapodus nubilus*, Cantor. Head above and back light reddish brown, paler on the sides; cheeks gill-covers and abdomen silvery white; an indistinct blackish oblique band from the nape of the neck to the point of the opercle; a second similar in front of the dorsal, terminating beneath the lateral line in a large rounded spot; a few indistinct blackish clouded spots along the sides; the scales of the body indistinctly edged with brownish and minutely dotted with brown; dorsal caudal and anal pale yellowish; pectorals and ventrals white, the posterior half of the latter pale blackish: the fin-membranes minutely dotted with brown. Iris pale golden. A number of minute pores on the infraobital bones, the cheeks, the margin of the preopercle and on the lower jaw. D 10/9, C 17½, A 3/8, V 1/5, P 13, Br. VI. Inhabits *Sea of Pinang*. Total length, 4⅜ inch. The head is elongated, the profile much sloping, its length, when the muzzle is protracted, is ⅓ of that of the body, the tail not included. The eye is situated behind the centre of a line drawn from the protracted muzzle to the point of the opercle; its diameter is a little less than ⅓ of the length of the head. The canines of both jaws are very small; there are 4 in the upper, 6 in the lower, of which the two outer ones are the largest and slightly outwards arched. The pores are very minute, scarcely perceptible by the naked eye, rather closely distributed over the infraorbitals, the cheeks, the margin of the preopercle and the lower jaw. The lateral line is very distinct, following the outline of the back. The scales are very finely ciliated: there are about 47 on a straight line. This species is closely allied to *P. porosus*, Cuv. and Val. from which it differs in the eye being situated farther back, in the comparatively longer pectoral fins, the second and third upper rays reaching the anal spine, and in the comparative greater length of the anal spines. The anterior of the latter is half the length of the second and third, which are equal and of nearly the same length as the succeeding soft rays. The description is taken from a solitary individual, observed at Pinang in 1844.

Genus. SPONDYLIOSOMA, *Cantor*. Σπονδύλιον spindle; σῶμα, body. Substituted for and Equivalent to *Cantharus*, Cuvier, 1829, pre-occupied by *Cantharus*, Montfort, 1808, *(Polypi.)* Teeth card-like, close, the external series a little stronger than the rest and slightly curved: mouth slightly cleft, not protractile.

(3662) *Spondyliosoma guliminda*, (Cuv. & Val.)

Syn. Russell CVII. Lama Guliminda.
Cantharus guliminda, Cuv. and Val. VI. 344.

Young. Head above, back and sides above the lateral line rose-coloured; the latter bordered beneath by a pale blue line; sides and abdomen silvery with five parallel straight longitudinal lines, each rose-coloured, bordered beneath with pale blue; cheeks and opercles silvery, washed with rose colour; beneath the orbit an elongated blue spot; a larger on the opercle. Dorsal fin whitish transparent, either pale blue at the base, or with a bluish line behind each spine; the spiny part edged with vermilion; anterior half of caudal bluish, posterior pale crimson; the other fins whitish transparent; the anal membrane in some bluish near the margin. *Adult.*—Head above and back vermilion; ground-colour of the upper half of the sides greenish grey, of the lower and of abdomen silvery, from the occiput a golden longitudinal band bordering the back; the lateral line bordered above by a crimson, beneath by a golden band; the scales at the origin of the lateral line broadly edged with crimson, forming a large rounded spot, from which proceeds a straight longitudinal crimson band, bordered beneath by a narrower golden band, beneath which four similar parallel bands, gradually lengthening and becoming paler towards abdomen. Infraorbitals silvery crimson; cheeks and opercle crimson; preopercle violet silvery; caudal rose-colored; the other fins transparent white; dorsal edged with vermilion. Iris golden, upper margin bluish black. D 10/9, C 17½, A 3/7, V 1/5, P 17, Br. V. Inhabits *Sea of Pinang*, Madras, Vizagapatam. Total length: 6 inch. The head is ¼ of the total length to the centre of the posterior margin of the caudal; the greatest vertical diameter of the body equals the length of the head; the horizontal diameter of the eye is ⅓ of the latter; the eye occupies the second third. The ascending margin of the preopercle is finely toothed, the angle rounded; on its outer surface as well as on the

infraorbitals appear some distant minute pores. The upper lobe of the caudal is longer than the lower, and the third upper ray terminates in a not very long filament, which is also the case with the first ventral ray. The following errors occur in Russell's figure. The first dorsal spine is too short, its length in the fish is $\frac{3}{4}$ of the second. The pectoral is also too short, its length being equal to that of the head; the dorsal rays likewise: their length slightly exceeds that of the spines. The anal fin is erroneously represented with one spine: it has three, the first of which is $\frac{1}{2}$ of the second, which is but little shorter than the third. The ventral spine is one half the length of the head and equals the 10th dorsal, which slightly exceeds the preceding. All the spines are very slender and flexible. Single, mostly young individuals occur, but rarely, at Pinang.

Genus CRENIDENS, *Cuvier and Valenciennes*, 1830. The jaws with crenulated teeth, behind which others globular.

Sub. Gen. GIRELLA, (*Gray,*) *Richardson.* Teeth curved, flat and expanding towards their ends which are tricuspid, standing out in three rows on the margin of the jaw; a little way behind them a brush like band of much smaller teeth which are also tricuspid and like the others, except in size. Founded upon *Crenidens punctatus*, Richardson, (Report 1845, 242,) of which a figure appears in *Ill. Ind. Zool.* under the name of *Girella punctata.*

(3663) *Crenidens sarissophorus*, Cantor.

Pl. I. Figs. 1-4.

Young.—Head, back and sides above the lateral line pale umber brown; rest of the sides and abdomen silvery buff; all the scales broadly edged with pale umber; spines buff, minutely dotted with dark brown; fin-membranes and rays buff, so closely dotted with dark brown, as to appear a shade darker than the body. Iris pale golden, orbital margin blackish. D 11/15, C 15/7, A 3/14, V 1/5, P 19, Br. V. Inhabits. *Sea of Pinang, Malayan Peninsula.* Total length: $7\frac{5}{8}$ inch. The form is elongated oval; the abdominal profile a little less arched than the dorsal. The vertical diameter at occiput is $\frac{1}{4}$, at the fifth dorsal spine $2\frac{3}{4}$, between the last dorsal and anal rays $\frac{1}{5}$ of the total length. The body is much compressed, particularly towards the back; the greatest thickness is at the lower third of the vertical diameter, where it equals $\frac{1}{2}$ the length of the head. The muzzle is obtuse; the forehead a little arched between the eyes; the length of the head is $\frac{1}{4}$ of the total; the eye is placed high up, its horizontal diameter is about $3\frac{1}{2}$ of the length of the head; the distance from the muzzle equals the diameter. The posterior opening of the nostril is an almost vertical fissure immediately in front of the eye; the anterior is oval and situated a little behind the muzzle; the infraorbital bone is very large, occupying nearly the upper half of the cheek, it is tumid and of an elongated, nearly oval shape; the preopercle is narrow and obscurely ridged, with a single minute spine at the angle; the opercle terminates in two widely separated flat points; the subopercle and interopercle are small. The scales of the head are very small, those of the cheek less indistinct than on the other parts of the head. The mouth is small, both jaws of equal length; their teeth are curved, flat, widening towards the three cusps, of which the centre one is a little larger than the lateral ones; the outer series consists of about 18 teeth gradually increasing in length towards the angle of the mouth; immediately behind, and in close contact with the outer, appears a second series of similar teeth; at a little distance behind these two series are two others also consisting of tricuspid teeth, but much smaller and almost setaceous; at the angle of the mouth the teeth of all four series coalesce, and have no interval between them. The gill-opening is small linear, and the five branchiostigous rays are completely hid in the membrane; the suprascapular bone is naked. The body is covered with scales of different sizes; the largest are those of the sides, from immediately beneath the lateral line as far as the pectorals extend, they appear bony and tumid; the posterior rounded margin carries upwards of 40 minute spines; their vertical diameter, nearly double the length of the horizontal, is about $\frac{1}{2}$ of the diameter of the eye. From the apex of the pectorals the scales gradually decrease in size towards the caudal. The scales above the lateral line and those of the abdomen are much smaller than the rest; all are placed in irregular series, so that their number cannot be counted. The lateral line is a little below the upper fourth of the side; it consists of minute single tubes and follows the profile of the back towards the tail, in the middle of which it proceeds straight to the root of the caudal. The anterior dorsal spine, about $\frac{1}{2}$ of the diameter of the eye, is situated at the anterior third of the total length; it is immoveable, placed horizontally, has no membrane and becomes more or less hidden by age; the second spine is the shortest of all, about $\frac{1}{4}$ of the diameter of the eye; the third is $\frac{3}{4}$, the fourth exceeds by $\frac{1}{4}$ the diameter of the eye; the fifth is excessively long, robust and appears to be composed of two parts; the lower half, when reposing, covers with its grooved posterior margin the sixth spine; the upper half overlaps the succeeding five spines; the length of the fifth is $\frac{1}{5}$ of the greatest vertical diameter of the body, from the root of this spine. The rest of the spines gradually decrease in length towards the tenth, which equals the diameter of the eye; the eleventh exceeds it by $\frac{1}{4}$ and is closely attached to the anterior dorsal

ray. The first four dorsal rays are the longest, of equal length, $\frac{3}{5}$ of the head; the rest gradually decrease, the fifteenth, double one, being $\frac{1}{3}$ of the first. The caudal is almost truncated, the central rays being but a little shorter than the rest, which are $\frac{2}{3}$ of the length of the head. The anal rays resemble the dorsal; the spines are strong, the second, the longest, about $2\frac{1}{2}$ of the head. The anus is situated a little in front of the first spine. The pectoral is nearly triangular, the longest ray $\frac{3}{4}$ of the head. Each ventral is enclosed by two elongated scales; the spine is $\frac{1}{2}$ of the length of the head; the anterior ray is undivided, filamentous, its length equals that of the head; from the second, which slightly exceeds the spine, the rest gradually decrease. The individual described was observed at Pinang in August 1845. The fishermen declared it to be a young one, and of rare occurrence. A second, of somewhat larger size, was taken on the coast of Malacca.

(Sub-Fam. MÆNOINÆ.)

(3664) *Cæsio*, (*Commerson*) *Cuv. and Val.* 1830. (*Cæsio*, Lacepede, 1800, is founded upon erroneous characters.) Dorsal and anal fin covered with small slender scales; mouth very slightly protractile; no teeth on the vomer; a pointed scale above the root of each ventral, and a third between the fins; on the occiput a chevron or crescent with the horns backwards pointed.

(3665) *Cæsio cærulaureus*. Lacepede. Var. (Lacep. III. 86.—*Picarel raillard*, Quoi and Gaim. Freycin, 290, Pl. 44, fig. 3.—Cuv. Val. VI. 434.) Head above and back deep blue, changing to bluish olive on the sides; an indistinct golden line from the orbit along the sides, in the centre of which it changes to silvery blue, continued to the root of the caudal; opercle golden; cheeks, preopercle, subopercle and interopercle, lower half of the sides and abdomen silvery glazed with cherry red; dorsal pale olive grey, the membrane minutely and closely dotted with brown and edged with black; caudal membrane black, rays yellowish olive, the upper, lower and posterior margin cherry; ventrals and the spiny part of anal white, the membrane of the soft anal rays pale cherry; the three upper rays of the pectoral white, the rest pale cherry; on the inner side at the root a large black spot, continued as a small black point outside at the root of three upper rays. Iris golden, the orbital margin blackish. D 10/15, C $17\frac{1}{2}$, A 3/12, V 1/5, P 21, Br. VI. Inhabits *Sea of Pinang*. Total length: $6\frac{3}{8}$ inch. The scales are large, deciduous; there is no crescent-shaped space on the occiput, which is uniformly covered with scales, which advance on the crown as far as midway between the eyes. The present nearest approaches the Variety from the Red Sea, which Prof. Ehrenberg denominated *cæruleo-tæniatus*; it also resembles *C. chrysozona*, Kuhl and Van Hasselt, apud Cuvier and Valenciennes. As the distribution of colours of *C. cærulaureus* is liable to considerable variations, *chrysozona* may turn out to be but a Variety. The description of the present was drawn up from a single dead specimen, observed in the fish-bazar at Pinang in 1845. The fishermen were unacquainted with the fish, and had on that account put it aside.

Genus CATOCHAENUM. *Cantor*. Κάτω, downwards; χαίνων, yawing. Substituted for *Gerres*, Cuvier, 1829, pre-occupied by *Gerres* (Latr.) Fabricius 1794, (*Hemiptera*) (Equivalent to GERRES, (*Cuvier*.) Mouth very protractile downwards; the jaws with velvety teeth the angle and inferior margin of the preopercle minutely toothed in some, in others not: opercle terminating in an obtuse angle; body compressed, high; chest square beneath; head, cheeks and opercles like the body with large, deciduous scales: anterior dorsal and anal spines more elongated than the rest; the base of these fins is hid in a scaly sheath; the ventral fins with an elongated scale above the root.

(3666) *Catochænum limbatum* (Cuv. and Val.).

SYN. Gerres limbatus. Cuv. and Val. VI. 476.

Silvery with lilac reflections; dorsal, caudal and anal fins pale yellow; dorsal spines, rays and membrane minutely dotted with brown, the upper margin black, caudal with a broad blackish margin; ventrals and pectorals white. Iris silvery or pale golden. D 9/10, C $17\frac{1}{2}$, A 3/7 or 8, V 1/5, P 15 or 16, Br. VI. Inhabits *Sea of Pinang*, Malabar, Pondicherry. Total length: 7 inch. The greatest vertical diameter is contained three times and one-third in the total length. The length of the second dorsal spine is contained two and a half times in the vertical diameter. In the adult this spine slightly exceeds the third in length, but in the young the two spines are of equal length, and the lower margin of the preopercle is finely toothed, of which all trace is obliterated in the adult. The blackish margin of the caudal is very indistinct in the young, which bears a strong resemblance to *Catochaenum lucidum* (Cuv. and Val.). Young individuals of this species are exceedingly numerous at Pinang at all seasons, and large quantities are dried. Large individuals are of comparatively rare occurrence.

(3667) *Catochaenum filamentosum* (Cuv. and Val).

SYN. Russell LXVII. Woodawahah.
Gerres filamentosus, Cuv. and Val. VI. 482.
Gerres filamentosus, Bleeker: Ver. Bat. Gen. XXII., 4.

Head above and back pale greenish grey, the rest of body silvery with lilac reflections; above and following the lateral line two parallel series of large oval blackish spots; below the lateral line one or two straight series of similar, but smaller

spots; dorsal, caudal and anal fins pale yellow; the spines, rays and membranes of the dorsal and caudal minutely dotted with brown; the superior margin of the dorsal black; the posterior margin of the caudal pale blackish; ventrals and pectorals white. Iris pale golden. D 9/10, C 17½, A 3/7, V 1/5, P 15, Br. VI. Inhabits *Sea of Pinang*, Madura, Vanikolo, New Guinea, Java, Coromandel. Total length: 7⅛ inch. The length of the second dorsal spine appears to vary: in an adult and a few young, it but slightly exceeded the vertical diameter of the body, and did not reach the caudal fin, as described by M.M. Cuvier and Valenciennes. The young ones have no series of blackish spots, which vanish soon after death; in the smallest examined, 4⅛ inches in length, the margin of the preopercle was not toothed. This species but rarely visits Pinang.

Fam. SCIÆNOIDÆ.

Sub-Genus OTOLITHUS, *Cuvier* 1829. Head gibbous, supported by cavernous bones; preopercle toothed or crenulate; bony opercle terminating in one or two flat points; dorsal fins two, or one deeply emarginated, the soft part of which longer than the spinous; anal spines extremely small; strong canines in the upper jaw, and in some also in the lower; under the symphysis of the latter two very minute pores, or none: air-vessel in some, [M.M. Cuvier and Valenciennes add (*Hist. Nat. des Poiss.* V.) that such is the case in the species dissected by them,] with a hornlike, forwards directed process on each side; in others with numerous lateral branched appendages. Vide infra *Otolithus ruber* and the subsequent species, a very large loose bone in each auricular cavity; branchiostegous rays 7. The Malays distinguish the fishes belonging to the Genus *Otolithus* by the common denomination of *Járang* (distant, open), *gigi* (tooth).

(3668) *Otolithus biauritus*, Cantor. Ikan Salampai, sometimes Jarang gigi, of the Malays. *Adult.* Head above and back greenish grey with golden reflections; sides golden orange, paler towards abdomen, everywhere minutely dotted with brown; lateral line golden: dorsal, caudal and anal fins brownish yellow or pale orange, minutely dotted with brown, black towards the margin; ventrals pale orange; pectorals brownish with a black spot in axilla, spreading over the basal third of the nine upper rays. Iris golden orange. *Young.* Paler than the adult; abdomen silvery buff; upper half of opercle silvery bluish black; the spot in the axilla very indistinct or absent. D. 9—1/27; 9—1/30; 9—1/32; 8—1/32; C 17½, A 2/7, V 1/5, P 19, Br. VII. Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Singapore*, *Lancavy*, Tenasserim Provinces. Total length: 3 feet. This fish is of a very elongated cylindrical form, not unlike that of the Genus *Ophiocephalus*; the profile of the back and abdomen is nearly horizontal, imperceptibly sloping towards the bluntly pointed muzzle. The length of the head is from 4½ to ⅕ of the total; the depth at occiput exceeds by ⅛ half the length of the head. The eye occupies about the second eight of the length of the head; the anterior upper half of the orbit borders upon the profile, while the posterior half deviates downwards; the greatest oblique diameter is ⅓ of the length of the head, while the vertical is but ⅔ of the oblique diameter. The head above is depressed, slightly arched between the eyes, the distance of which is about double the oblique diameter. The nostrils open closely in front of the eye: the posterior obliquely oval aperture is but little larger than the minute rounded anterior, the margin of which is provided with a small raised membranous fold. The mouth is large; the widely arched upper jaw is hidden when the mouth is closed, by the scaly fold which covers the infraorbitals; the lower jaw is scaly, narrower, more pointed, and slightly shorter than the upper, which is naked, with longitudinal striæ, and a rather large triangular impression near the angle, which is situated opposite the posterior part of the orbit. In the upper jaw appear an external series of pointed inwards arched, distant teeth. On each side of the symphysis is one or two canines, larger than the rest; the other teeth gradually decrease in size towards the angle of the mouth. At a slight interval behind the external appears a second narrow series of minute crowded conical (cardlike) teeth. In the lower jaw the external series consist of conical teeth, although small, yet perceptibly larger than the card-like ones of the upper jaw. The internal series consists of single distant large teeth, increasing in size as they approach the angle of the mouth. The tongue is large triangular, pointed, fleshy, on each side of the base, flat, bony in the centre, membranous towards the margins and the apex. The angle of the preopercle is rounded, the ascending margin is but very indistinctly crenulated. The bony part of the opercle terminates in two flat points of which the upper is the smaller; both are enveloped in a membranous point, projecting beyond the root of the pectoral fin, and formed by a prolongation of the subopercle. The third upper branchiostegous ray is very broad, like the blade of a sabre. Above the pointed termination of the opercle appears another, triangular point, formed by a lobe of the skin, the scales of the margins of which terminate in short setaceous points. This second, earlike appendage also appears in *Otolithus puna*, [*Syn Bola puna*, Buchan. Ham. 79, 368, Pl. 32, Fig. 26—*Sciæna puna*, Cuv. and Val. V. 55, Pl. 101, who observe it might with equal propriety be considered a species of *Otolithus*. Their description appears to have been drawn up from young specimens, in which the canines are less developed than in the adult, in

which they appear as strong and conspicuous as in several species of *Otolithus*. The form of the air-vessel is not exclusively characteristic of *pama*.] (Buchan. Ham.) The body is elongated, cylindrical, compressed towards the back; the vertical diameter taken in front of the dorsal fin is 6⅓ of the total length. The dorsal spines are very slender; the third is the longest, equalling about ½ of the vertical diameter; the rest gradually decrease towards the ninth, but the last spine is longer, nearly ½ of the third. The caudal fin is rhomboidal very pointed, its length from 6½ to 7½ of the total. The pectorals are very pointed 5⅔ to 6½ of the total. The ventrals and the anal are equal ½ of the length of the head. The second anal spine is scarcely one half of the length of the rays, very attenuated, and not striated. The scales of the body are moderate, deciduous; the lateral line is very distinct and proceeds obliquely downwards to the very point of the caudal. The air-vessel is nearly one half of the total length, narrow, tapering backwards to a fine point. On each side of the latter commences a narrow tape-like process, which, continuing along each side, deviates at a little distance from the fundus of the air-vessel, which it again joins. The organ might be compared with an elongated antique urn with two handles. From the anterior part of each of the latter proceed five branches, the four of which give off smaller ones to each side, and the fifth is tortuous and larger than the rest. This organ strongly resembles that of *O. pama*, (Cuv. and Val. V. Pl. 138,) yet it presents differences more easily perceived by comparison than described. This species approaches to *O. senegalensis*, Cuv. and Val. and to *O. pama*, from which latter it, however, differs in its more elongated form, particularly of the head, and in having much fewer rays in the dorsal fin. *O. Reevesii*, Richardson, (Rep. 1845. 224.) differs in having 10—1/31 in the dorsal fin, the preopercle spinously toothed on the upper limb and rounded corner, where the teeth are large, and in having the second anal spine stout and finely striated. Single individuals occur at Pinang at all seasons, but numbers from June to August. Although not much esteemed by Europeans, this fish is consumed by the natives both fresh and dried. It yields a large quantity of isinglass, which in the Chinese market is considered to be of the best quality, and fetches 40 to 45 Spanish Dollars per Pikul.

(3669) *Otolithus ruber*, (Bloch-Schneider.)

Syn. Johnius ruber, Bloch Schn. 75, No. 3 Pl. 17.
Otolithus ruber, Cuv. and Val. V. 60, Pl. 102.
Otolithus raber, wainSson, Nat. Hist. Fish. II. 219.
Jarang gigi of the Malays.

Adult. Head above and back pale brownish el with silvery, iridescent reflections; sides of the head and parts beneath the lateral line reddish or pure shining silvery; upper part of opercle steel-blue; lateral line silvery; dorsal pale brownish red, the membrane minutely dotted with brown; the other fins pale reddish yellow. Iris reddish golden brown, towards the orbit. *Young.* Sides of the head and parts beneath the lateral line silvery pale orange. D 10—1/29 or 30, C 17⅔, A 2/7, V 1/5, P 16, Br. VII. Inhabits *Sea and estuaries of Pinang, Malayan Peninsula, Singapore*, Coromandel, Malabar. Total length: 2 feet 6 inch. The length of the head is 3½ times in the total; its vertical diameter equals the distance from the muzzle to the anterior margin of the preopercle, or exceeds by ⅛ half the length of the head. The greatest oblique diameter of the eye is ⅙ of the length of the head. The depth of the body in front of the dorsal is contained 4¾ times in the total length. In the young, the caudal fin is rhomboidal, pointed; but with age it becomes rounded, and its length little less than ⅙ of the total. On each side of the symphysis of the upper jaw appear two large arched canines, of which the exterior is the shorter: between the two pairs rise two distant smaller, yet conspicuous teeth. On each side of the symphysis of the lower jaw appears a long canine; in most individuals but one such is visible, the corresponding one being either missing or much smaller. Behind the canines both jaws have an external series of small conical teeth, and in the upper appears an inner series of velvety teeth. But the lower jaw has but a few such behind the canines on the symphysis. The stomach is elongated, cylindrical with four cœcopyloric appendages. In several it contained remains of fishes, of a small *Melania* and *Crustacea*. The air-vessel is large, flattened, broad lanceolate, terminating behind in a short point. Its length is ½ of the body, the caudal not included. On each side of the body of the vessel appear 34 processes, of which the anterior four or five divide in four branches, the next in three, the next in two, but the posterior process, which are slightly longer than the preceding, are simple; all again divide in minor ramifications. The isinglass is considered very good, and sells in the Chinese market from 40 to 45 Spanish dollars per Pikul. The fish is consumed both in a fresh and dried state. Single individuals occur at Pinang at all seasons, but they are plentiful from June till August.

(3670) *Otolithus argenteus*, Kuhl and Van Hasselt.

Syn. Otolithus argenteus, Cuv. and Val. V. 62.
Otolithus argenteus, Richardson, Rep. 1845. 225.
Otolithus argenteus, Bleeker: Verh. Bat. Gen. XXII. 4.
Jarang gigi of the Malays.

Adult. Head above and back iridescent grey-

ish green, with pale reddish reflections; sides of the head and beneath the lateral line reddish golden; upper part and posterior margin of opercle blackish blue; membrane of the whitish dorsal spines reddish transparent, of the rays and caudal reddish yellow, minutely dotted with brown, margin black; pectoral, ventrals and anal pale yellowish red; ventral and anal spines whitish. Iris golden, bluish black towards the orbit. *Young.* Sides of the head and beneath the lateral line pale golden orange; upper part of opercle steel blue; soft dorsal, caudal, anal, ventrals and pectorals orange or yellowish red more intense than in the adult. D 9 or 10 — 1/26, 27 or 28, C 17$\frac{5}{6}$, A 2/7, V 1/5 P 20, Br. VII. Inhabits *Sea and estuaries of Pinang, Malayan Peninsula, Singapore*, Malabar, Celebes, Madura, Batavia. Total length: 2 feet 7 inch. The length of the head is $\frac{1}{4}$ of the total, its greatest vertical diameter exceeds by $\frac{1}{4}$ half the length of the head. The oblique diameter of the eye is 5$\frac{1}{3}$ of the length of the head. The vertical diameter in front of the dorsal is 5$\frac{1}{2}$ of the total length. On each side of the symphysis of the upper jaw appear two, sometimes three canines, of which the posterior, or centre one when three are present, is the longest, but all are shorter and more distant than those of *O. ruber*. The canines are succeeded by a series of distant conical teeth of a comparatively larger size than those in *O. ruber*. Behind the external series is an inner one of velvety teeth. On each side of the symphysis of the lower jaw is a very small canine, preceding a series of velvety teeth, behind which is an inner series of large distant conical teeth, some of which in size exceed the lower canines. The lateral line describes an arch, terminating opposite the middle of the soft dorsal fin, from whence it proceeds horizontally to the point of the caudal. The latter fin is rhomboidal; its length about 5$\frac{1}{2}$ of the total. The stomach is elongated, cylindrical, containing fishes and *Crustacea*. There are six cœcopyloric appendages. The body of the air-vessel is very narrow, lanceolate, about $\frac{1}{4}$ of the length of the fish, terminating in a fine point. From each side of the body of the air-vessel proceed 25 branched processes, of which the anterior are the longest and have the greatest number of branchlets. At Pinang this species is taken in numbers from June till August. It is valued by the natives as an article of food. Owing to the small size of the air-vessel, it yields but a small quantity of isinglass, the quality of which however is considered very good. M.M. Cuvier and Valenciennes have observed this species figured in Colonel Farquhar's collection of drawings at the India House, and its name is said to be at Malacca; *Ikanhampay*, which most likely is a mistake for *Salampai*, the Malayan denomination of *O. bilauritus*.

(3671) *Otolithus maculatus*, Kuhl and Van Hasselt.

Syn. Otolithus maculatus, Cuv. and Val. V. 64.
Jarang gigi of the Malays.

Head above and back iridescent yellowish brown, lighter, silvery on the sides; cheeks, preopercle and abdomen silvery buff; upper part of opercle steel blue; lateral line shining silvery; on the back and sides to within a little beneath the lateral line, a number of brownish spots, the scales of each spot edged with black; dorsal, anal, ventral and pectoral fins yellowish light grey, their membranes minutely dotted with brown; caudal rays silvery at the base; posterior half and membrane brownish yellow; single large irregular black spots scattered over the fin. Iris pale golden, blackish towards the orbit. D 10—1/34, C 17$\frac{5}{6}$, A 2/11, V 1/5, P 18, Br. VII. Inhabits *Sea and estuaries of Pinang, Malayan Peninsula, Singapore*, Batavia. Total length: 2 feet 9 inch. The length of the head is 3$\frac{3}{4}$ of the total; its greatest vertical diameter exceeds by $\frac{1}{7}$ half the length of the head. The oblique diameter of the eye is a little more than $\frac{1}{6}$ of the length of the head. The vertical diameter of the body in front of the dorsal is 5$\frac{1}{2}$ of the total length. The dentition resembles that of *Otolithus ruber*, but the external series of the lower jaw consists of fewer, more distant and stronger conical teeth. The lower jaw greatly projects beyond the upper. In the adult the caudal fin is nearly rounded; its length is 7$\frac{3}{4}$ of the total. The pectorals and ventrals are comparatively short, their length equalling that of the caudal. The stomach is very elongated, cylindrical, thin. In it were found fishes, shells of a *Cerithium*, and *Crustacea*. The air-vessel is very large, broad lanceolate, tapering behind into a fine point. The length is one half of the body, the caudal fin not included. Each side has from 52 to 55 branched processes, the number of which differs not only individually, but from side to side. The lower abdominal surface of the body of the vessel is perfectly smooth, and as usual, silky white, but the upper or vertebral surface is longitudinally divided by a narrow furrow, from which proceed a number of distant, backwards arched, transversal lines or ribs. The intervals between the latter are filled up by short backwards bifurcating raised lines, of which those nearest the central furrow are directed obliquely inwards; but they increase in length, and become longitudinal towards the margin of the vessel, while those covering the lateral branched processes deviate outwards and are much longer than the rest. Thus the whole of the upper or vertebral surface of the air-vessel presents a kind of raised net-work of singular beauty. This species, although not uncommon, appears at Pinang to be less numerous than the others, which it accompanies. It is reported to

be flavourless, but it is highly valued for the sake of the air-vessel, which yields a considerable quantity of the best kind of isinglass.

(3672) *Otolithus versicolor*, Cuv. and Val. ?

Syn. Russell CIX. Pottee Kanasah ?
Otolithus versicolor, Cuv. and Val. V. 64 ?
Jarang gigi of the Malays.

Young. Head above and back iridescent greyish green, lighter on the sides; cheeks and preopercle silvery; opercle steel-blue; sides beneath the lateral line silvery white; lateral line shining silvery; fins yellowish buff; membrane of the spinous dorsal and marginal half of the soft, of the anal and caudal minutely dotted with black, on the latter fin so closely as to produce a general blackish colour. Iris arrow golden round the pupil; the rest bluish black. D 10—1/25, C 17$\frac{1}{3}$, A 2/7, V 1/5, P 18, Br. VII. Inhabits *Sea of Pinang*. Total length: 6$\frac{1}{8}$ inch. The length of the head is about $\frac{1}{4}$ of the total; its greatest vertical diameter exceeds one half the length by $\frac{1}{7}$. The oblique diameter of the eye is 5$\frac{1}{2}$ of the length of the head. The vertical diameter in front of the dorsal is about $\frac{1}{6}$ of the total length. The dentition, as represented by Russell, resembles that of *O. maculatus*. The broad triangular part of the upper jaw at the angle of the mouth, is finely radiated, but without the large triangular impression, which appears in some of the other species. The second anal spine is proportionally stronger than in the other species; its length slightly exceeds $\frac{1}{2}$ of the anterior ray, and the two lateral surfaces are compressed, finely radiated, whereas in the preceding species this spine is rounded. The air-vessel is lanceolate with numerous lateral branching appendages; its length equals that of the head, or about $\frac{1}{4}$ of the total length. The only individual observed, occurred at Pinang in 1844. It resembles more *O. versicolor* than any of the preceding species: Russell indeed gives 21 dorsal rays, but their number varies considerably in all. In the present, as well as in the young of the preceding, the caudal fin is proportionally much longer and more pointed than in the adult, and the eye is also proportionally larger.

Genus JOHNIUS, *Bloch-Schneider*, 1801. Velvety teeth in both jaws: in the upper an external series of arched teeth, considerably longer and more distant than the rest; in the lower an internal series of conical teeth somewhat longer than the rest. Differs from *Sciæna* by the comparative greater thickness and length of the second anal spine, which is nearly two thirds of that of the first ray.

(3673) *Johnius dussumieri*, (Cuv. and Val.)

Syn. Corvina dussumieri, Cuv. and Val. V. 119.

Head above and back dark greenish brown, paler, silvery on the cheeks, preopercle and sides; opercle steel-blue; the scales minutely dotted with brown; abdomen pearl-coloured; membrane of dorsal transparent, minutely dotted with brown, edged with black; caudal and anal yellowish white, minutely dotted with black, their marginal part blackish; ventrals white; upper half of pectorals brownish, lower yellowish white. Iris silvery, upper part bluish black. D 10—1/28 or 29, C 17$\frac{1}{3}$, A 2/7, V 1/5, P 19, Br. VII. Inhabits *Sea of Penang, Malayan Peninsula, Singapore*, Malabar. Total length: 6$\frac{1}{8}$ inch. The teeth of the external series of the upper jaw are distant, but little longer than those of the internal. Under the symphysis of the lower jaw appear five pores. The anterior part of the air-vessel is dilated, forming a rounded lateral process on each side of the vertebral column. Immediately behind them the body of the vessel is constricted, and the rest presents a broad lanceolate form, tapering backwards into a sharp point. From each side proceed ten processes of which the eight are branched, but the two posterior pairs, the longest, are either simple or bipartite. The length of the air-vessel is about $\frac{1}{4}$ of the total. At Pinang single individuals occur at all seasons. The isinglass is reputed good, but as the fish is of small size and not numerous, but little is procurable.

(3674) *Johnius belengeri*, (Cuv. and Val.)

Syn. Corvina belengeri, Cuv. and Val. V. 120.
Corvina belengeri, Belanger, 358.

Colours similar to those of *J. dussumieri*, but the body and fins so closely dotted with black and brown as to impart a general pale brownish appearance; the marginal half of the caudal, anal and ventral fins blackish. Iris silvery, upper half bluish black. D 10—1/28, 29 or 30, C 17$\frac{1}{3}$, A 2/7, V 1/5, P 17, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Malabar. Total length: 6$\frac{1}{8}$ inch. The teeth of the external series of the upper jaw are less distant, and rather longer than in *J. dussumieri*. There are five pores under the symphysis of the lower jaw. The form and length of the air-vessel is that of *J. dussumieri*; each side has ten branching processes, shorter, however, and apparently placed at a greater distance from each other than in the former species. The three posterior pairs are much longer than the preceding, the eighth and ninth bipartite, the tenth pair is undivided, pointed. Also this species occurs singly at Pinang. The two preceding species not only closely resemble each other, but also a third: *Johnius coitor*, (Buchanan Hamilton.) [*Syn. Bola coitor*, Buchan. Ham. 75, 368, Pl. 27, Fig. 24. —*Corvina coitor*, Cuvier and Valenciennes, V. 116.] Their external distinguishing characters will appear from the following table.

	Johnius dussumieri.	*Johnius belengeri.*	*Johnius coitor.*
Length of the head	4⅓ in total length	⅓ of total length	⅓ of total length
Depth at occiput	⅓ of the length of the head	⅓ of the length of the head	⅓ of the length of the head...
Diameter of the eye	⅓ of do.....	1⅓ in do.	5⅓ in do. .....
Distance from the muzzle to the eye	equal the diameter of eye,	⅛ less than the diameter	exceeding the diameter by ⅛
Depth in front of dorsal fin, ...	5⅓ in total length	⅓ of total length	⅓ of total .....
Length of the posterior anal spine.	slightly exceeding ⅓ of first anal ray,.....	⅓ of the first ray but slenderer than in *coitor.*	of the first anal ray .....

(3675) *Johnius carutta*, Bloch.

Syn. Johnius carutta, Bl. Pl. 356.
Corvina carutta, Cuv. and Val. V. 124.

Head above and back dark brown claret colour, lighter, silvery on the cheeks, opercles, sides and abdomen; the scales minutely dotted with black, and their margins of a darker brown than the ground colour; fin-membranes pale whitish yellow, minutely dotted with black; the upper half of the spiny dorsal, from 2d to 7th spine, black; the soft dorsal with four equidistant, large, oblique black spots; the marginal half of the caudal, anal and ventral fins blackish. Iris golden, the orbital half bluish black. D 10—1/28, C 17?, A 2/8, V 1/5, P 18, Br. VII. Inhabits *Sea of Pinang*, Malabar; sea and rivers Tranquebar, Pondicherry. Total length: 6 inch. The length of the head is 4⅓ in the total, the depth at the occiput ⅓ of its length. The transversal diameter of the eye is ⅓ of the length of the head, equal to its distance from the muzzle. The vertical diameter in front of the dorsal fin is little less than the length of the head. The external series of teeth of the upper jaw is but little larger than the external; the velvety teeth of the lower jaw, form a broader band than those of the upper. Under the symphysis of the lower jaw appear four pores. The second anal spine is very thick, ⅔ of the length of the first ray. A single individual was observed at Pinang in May.

(3676) *Johnius diacanthus.* (Lacepede.)

Lutjanus diacanthus, Lacepede IV. 195, 244.
Russell CXV. Nalla Katchelee. (*Adult.*)
Russell CXVI. Katchelee. (*Young.*)
Johnius cataleus, Cuvier R. A. II. 173 (4)
Corvina catalea, Cuvier and Valenciennes, V. 128.
(*Icon.*) Sciæna maculata, Gray, Ill. Ind Zool. II. Pl. 89, Fig. 3. (*Young.*)
Corvina catalea, Belanger, 360.
Corvina catalea, Richardson; Rep. 1845, 226.
Corvina nalla katchelee, Richardson l. c.
Corvina catalea, Bleeker: Verh. Batav. Gen. XXII. 4.
Ikan Tambareh of the Malays.

Young. Head above and back dark brown claret colour; cheeks, preoperele, and sides to a little beneath the lateral line lighter with lilac silvery reflection, the scales edged with dark brown, and the back and upper half of the sides with numerous larger and smaller round black spots; lower half of the sides silvery buff; the scales minutely dotted with brown; opercle silvery lilac or blue; dorsal and caudal fin membranes brownish buff; minutely dotted with brown, and with more or less numerous large black scattered spots; anal, ventrals and pectorals brownish buff at the base, the rest pale neutral tint, minutely dotted with brown, and the marginal half black. *Adult.* Head and sides darker, with or without indistinct black spots; sides beneath the lateral line pale silvery bluish or lilac brown; opercle blackish blue; branchiostegous rays and membrane pale lilac silvery; dorsal-caudal and anal membranes pale yellowish brown, minutely dotted with brown, with or without indistinct large dark brown spots; ventrals and pectorals yellowish brown, posterior half blackish. Iris silvery lilac, minutely dotted with brown; the orbital half, bluish black. D 10—1/24, C 17⅔, A 2/7, V 1/5, P 19 or 20, Br. VII. Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Singapore*, Malabar, Coromandel, Bay of Bengal, Gangetic estuaries, Tenasserim, Canton, China Seas, Madura, Java. Total length: 2 feet 9 inch. The length of the head is 3⅓ in the total, the caudal fin not included. In the young the latter fin is rhomboidal, very pointed, and its length equal to that of the head: but with age the point becomes worn, and in the adult the length is but ⅔ of that of the head, or equal to the depth at the occiput. The oblique diameter of the eye is a little less than ⅓ of the length of the head; the distance from the muzzle to the eye exceeds the diameter by ⅓. The vertical diameter in front of the dorsal fin is ⅓ of the total length. The teeth of the external series of the upper jaw are long, distant, and there is generally a canine on one or both sides, at a little distance from the symphysis. The lower jaw has a smaller canine on each side of the symphysis, and an internal series of longer conical teeth. Under the symphysis appear four large pores, and in some a fifth, very minute. The air-vessel, ⅓ of the length of the fish, is of a broad, lanceolate shape, tapering behind into a very elongated point. Each side has 20 to 24 processes, of which the two posterior pairs are simple or bipartite; the rest branching. The contents of the stomach of one dissected were the remains of a species of *Leptocephalus* and an eel, of Crustacea, and of a *Loligo*. At Pinang individuals of this species occur at all seasons, but in numbers and of the largest size, from June to August. They are not only valued as articles of food, but also on account of the quantity and quality of the isinglass, which sells in the China market from 40 to 45 Spanish Dollars per Pikul.

(3677) *Johnius maculatus*, Bloch-Schneider, Var.? [*Syn.* Russell CXXIII. *Sari Kullu.*—

Johnius maculatus, Bl. Schn. 75.—*Corvina maculata*, Cuvier and Valenciennes, V. 126.] Bloch, Schneider, Var ? Head above and back dark greyish green, lighter, silvery on the cheeks, opercles and sides, the scales minutely dotted with black, not, however, sufficiently to influence the general colour; abdomen silvery; membrane of dorsal spines transparent with black margin; between the anterior six spines dotted throughout, and rather largely with black and brown; between the four posterior spines the central part of the membranes without dots; membrane of dorsal rays, caudal and anal yellowish white, minutely dotted with brown and black, their marginal portion blackish; pectorals and ventrals whitish the latter dotted with black, particularly towards the margin. Iris silvery, dotted with black; upper orbital half bluish black. D 10—1/23, C 17$\frac{5}{6}$, A 2/7, V 1/5, P 19, Br. VII. Inhabits *Sea of Pinang*. Total length: 5 inch. The length of the head is 4$\frac{1}{3}$ in the total, its vertical diameter at the occiput $\frac{1}{4}$ of the length. The oblique diameter of the eye is 3$\frac{1}{2}$ in the length of the head; the distance from the muzzle is less than the oblique diameter. The vertical diameter in front of the dorsal fin equals the length of the head. The distance from the orbit, across the infraorbitals, exceeds, $\frac{1}{3}$ of the diameter of the eye. This character may serve at once to distinguish a very closely allied species: *Johnius chaptis*. [*Syn. Bola chaptis*, Buch. Ham. 77. 368, Pl. 10, Fig. 25.—*Corvina chaptis*, Cuvier and Valenciennes, V. 130.] (Buchan. Ham.), in which the breadth of the infraorbitals is much less. The anterior teeth of the external series of the upper jaw are rather long and closely set; the rest are scarcely longer than the rather broad internal series of velvety teeth. Under the symphysis of the lower jaw appear five pores. The lower part of the rounded margin of the preopercle is distinctly and distantly toothed. The opercle terminates in two flat spines. The laternal line is distinct; on each scale appears a small longitudinal tube, from whence proceed an upper and lower oblique process. Most of the scales of the sides have each a central oblique line. The second anal spine is rather strong, longitudinally radiated, and $\frac{1}{3}$ of the length of the first ray. The caudal fin is rhomboidal somewhat rounded at the point. From the defective descriptions of *Johnius maculatus*, it is impossible to determine if the present is specifically distinct or a variety. A single individual was observed in 1844 at Pinang. The form of the air-vessel and the number of the lateral appendages resemble those of *Johnius belengeri*.

Sub-Genus CORVINA, *Cuvier*, 1829. Differs from *Johnius* by the comparatively greater size of the second anal spine, the length of which nearly equals that of the first anal ray.

(3678) *Corvina Soldado*, (Lacepede.)

Syn. Holocentre soldado, Lacepede, IV. 341, 373.
Russell CXVII. Tella Katchelee.
Corvina [Misprinted "*Sciæna*."] miles, Cuvier and Valenciennes, V. 94, IX. 474.
Sciæna argentea, Kuhl and Van Hasselt MS. Cuv. and Val. V. 95.

Adult. Head above and back iridescent greyish green; lighter, silvery on the cheeks, preopercle and sides; opercle steel-blue in the centre; abdomen pearl-coloured; membrane of dorsal spines transparent, minutely dotted with black and brown, and with black margins; membrane of the rays near the root, and in front of each ray, with a small brownish spot; upper third minutely dotted with brown, the margin black; ventrals whitish; the rest of the fins pale yellowish white, the membranes and rays minutely dotted with black on the marginal half, so closely as to impart a general blackish colour. Iris silvery, upper orbital half bluish black. *Young*. Of general lighter colour; fins, of a deeper yellow; anal spines and three anterior rays and their membrane dotted with brown. D 10—1/29 or 9—1/30, C 17$\frac{5}{6}$, A 2/7. V 1/5 P 16 or 17, Br. VII. Inhabits *Sea of Pinang*, Java, Tenasserim, Coromandel, Bombay. Total length: 2 feet. The length of the head is about 4$\frac{5}{6}$ in the total; the depth at occiput $\frac{1}{7}$ less than the length. The oblique diameter of the eye is a little less than $\frac{1}{4}$ of the length of the head; the distance from the muzzle equals the diameter of the eye. The vertical diameter, in front of the dorsal, slightly exceeds the length of the head. The air-vessel is about $\frac{1}{3}$ of the total length, elongated oval, with numerous lateral branching appendages, which increase in length towards the posterior extremity. Four pores appear under the symphysis of the lower jaw. Small individuals occur at Pinang at all seasons; larger ones but rarely. The fish is eaten by the natives, and the few air-vessels procurable, are valued as good isinglass. M. Dussumier found this species abundant at Bombay.

Genus UMBRINA, *Cuvier*, 1817. Differs from *Johnius* in having a cirrus under the symphysis of the lower jaw.

(3679) *Umbrina russelli*, Cuvier.

Syn. Russell CXVIII. Qualar Katchelee.
Umbrina russelli, Cuv. and, Val. V. 178.
Umbrina russelli, Richardson Report 1845 226.
Ikan Gulama of the Malayas.

Young. Head above and back silvery greyish; green, light on the sides above the lateral line cheeks, opercles and beneath the lateral line shining silvery; from the vertex, between the eyes, a blackish band obliquely backwards over the temple, terminating on the opercle in a large steel-blue spot; behind the occiput a broader black

band obliquely downwards to the origin of the lateral line; membrane of the dorsal spines blackish, minutely dotted with brown; of the rays the upper half minutely dotted with brown and black, the lower transparent; the rest of the fins pale orange. *Adult.* Body paler; in certain lights reflecting fifteen obliquely backwards ascending lines; no trace of the blackish band of the temples, and but a faint of the occipital; a pale steel-blue spot on the opercle; membrane of dorsal spines brownish. Iris silvery, upper orbital half bluish black. D 10—2/27 or 10—1/26, C 17$\frac{1}{3}$, A 2/7, V 1/5 P 17, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Vizagapatam, Indian and China Seas. Total length: 6 inch. The length of the head is 4$\frac{1}{3}$ in the total; the depth at occiput $\frac{1}{7}$ less than the length. The oblique diameter of the eye is $\frac{1}{4}$ of the length of the head, equalling the distance of the eye from the muzzle. The vertical diameter in front of the dorsal fin is $\frac{1}{3}$ of the length of the body, the caudal not included, but with the lateral fin it is 3$\frac{2}{3}$ in the total length. The teeth of the external series of the upper jaw, are but little longer than the rest, and rather closely set. The cirrus is thick, fleshy; in the adult fish its length equals the lower jaw to the angle of the mouth, but it is shorter in the young. On each side of and a little behind the cirrus appear two large pores. The fold of the skin covering the infraorbitals and the upper maxillary forms a small rounded lobe on each side of the muzzle. The verticle distance from the lower part of the orbit down the fold is $\frac{2}{3}$ of the oblique diameter of the eye. The lateral line consisting of a small central tube on each scale, follows the arch of the back till opposite the middle of the anal, from whence it proceeds nearly straight to the point of the rhombic caudal fin. In individuals with 12 dorsal spines, the eleventh is slightly, the twelfth much longer than the tenth, and their membranes much narrower than those connecting the rest, which from the fourth gradually decrease in length. The pectorals are pointed, their length equalling that of the caudal. The second anal spine, $\frac{4}{5}$ of the first ray, is compressed, broad except near the root where it is somewhat narrowed. The air-vessel about $\frac{1}{3}$ of the length of the fish, is elongated oval, terminating in a long thin point. From each side proceed 14 to 16 appendages, of which the two posterior ones are simple or bipartite, and much longer than the preceding branching ones. At Pinang this species is of too rare occurrence to make it valuable as an article of food, or as yielding isinglass, although the latter is considered of good quality. The fishermen assert that individuals upwards of a foot in length have been taken.

Genus PRISTIPOMA, *Cuvier*, 1817. Dorsal fin single, and, as well as the anal, without scales; as observed by M. Swainson, this character does not exist in all species; angle of opercle blunt, or hid in the membrane; the external series of the velvety teeth stronger than the rest; under the symphysis of the lower jaw two pores, behind which a small fossety; branchiostegous rays seven.

(3680) *Pristipoma commersoni*, (Lacepede.)

Syn. Labre commersonien, Lacep. III. 431, 477, Pl. 23. Fig. 1.
Lutjan microstome, Lacep. III. Pl. 34, Fig. 2; IV. 181, 216.
Labrus commersonii, Shaw, IV. 493.
Pristipoma kaakan, Cuv. and Val. V. 244, XIII. 8[1].
Pristipoma commersonii, Cuv. and Val. V. 252.
Pristipoma kaakan? Ruppell: N. W. Fische, 123, Taf. 30, Fig. 1.
Pristipoma kaakan, Richardson: Report 1845, 227.
Pristipoma kaakan, Bleeker: Verh. Batav. Gen. XXII. 3.

Young. Head above and back pale greyish green; opercle bluish silvery, the posterior part minutely dotted with black; cheeks, sides and abdomen silvery; the back and upper part of the sides minutely dotted with black and with distant indistinct brownish spots; fin membranes transparent, between the dorsal spines, with a black margin and with two or three series of brownish spots; between the dorsal rays two transversal series of smaller brownish spots; posterior half of caudal pale blackish. Iris golden. D 12/14, C 17$\frac{1}{3}$, A 3/7 or 8, V 1/5, P 17, Br. VII. Inhabits *Sea and estuaries of Pinang, Singapore*, Sea and estuaries of Coromandel, Malabar, Island of Lantao, China Sea, Balli, Java, Sumbawa, Celebes. Total length: 7 inch. The length of the head and the greatest vertical diameter of the body are contained 3$\frac{1}{2}$ times in the total length. The fourth dorsal spine equals half the greatest vertical diameter of the body. The second anal spine is two third of the vertical diameter above it, and as long as the fourth dorsal, but stronger. Individuals of the length described are excessively numerous at all seasons at Pinang and Singapore, where they are consumed by the natives either fresh or dried.

(3681) *Pristipoma guoraca*, Cuv. and Val.

Syn. Perca grunniens, Froster?
Anthias grunniens, Bloch-Schneider, 308?
Russell CXXXII. Guoraka.
Pristipoma guoraca, Cuv. R. A. II. 176[1].
Pristipoma guoraca, Cuv. and Val. V. 256.
Pristipoma guoraca, Belanger, 363.

Head above and back pale blackish olive; cheeks, opercles and sides silvery grey with blue and golden reflections; abdomen silvery yellowish white; most of the scales have the edges minutely dotted with brown, and those above the lateral line a pale brown spot at the root, forming six or seven indistinct parallel lines; fins pale yellowish;

membrane of the dorsal minutely dotted with brown, between the spines one or two series of large clouded brown spots, and a single series of smaller between the rays; margins of the dorsal and caudal blackish; the membrane of the latter and of the anal slightly dotted with brown. Iris golden. D 12/14, C $17\frac{2}{3}$, A 3/8, V 1/5, P 18, Br. VII. Inhabits *Sea of Pinang*, Isle of Tanna, Batavia, Coromandel, Mahe (Fresh-water). Total length: 1 foot. The air-vessel is elongated, nearly one third of the total length, swelling in the middle, terminating in a point; the anterior extremity is blunt and appears to have on each side a pointed process, a little less than one third of the length of the vessel itself, which is restricted at the origin of the lateral processes. The second anal spine is excessively thick, striated on the anterior surface; its length slightly exceeds one half of the vertical diameter of the body above it, but it is considerably less than one half of the vertical diameter at the pectorals. This spine is therefore comparatively shorter in the present species than it is in *P. kaakan*, Cuv. and Val. which it however much resembles in distribution of colour and other characters. The fish is finely flavoured, but its isinglass is of little value, as the air-vessel is very thin. At Pinang it is of very rare occurrence.

(3682) *Pristipoma nigrum*, Mertens.

Syn. Pristipoma nigrum. Cuv. and Val. V. 258.

Young. Blackish brown, opercles pale silvery; membrane of dorsal spines pale brown with lilac reflections, margin black; soft part of dorsal and anal blackish brown with whitish yellow margin; pectorals and caudal whitish yellow with a blackish vertical band at the root; ventrals blackish brown. Iris King's-yellow with a black orbital margin. D 14/16, C $17\frac{2}{3}$, A 3/7, P 17, Br. VII. Inhabits *Sea of Pinang*, Manila. Total length (*of the young*): $2\frac{4}{8}$ inch. The head is $\frac{1}{3}$ of the length of the body, not including the caudal which is $\frac{1}{5}$ of the total length. The greatest vertical diameter of the body is $\frac{1}{3}$ of the total length. The eye occupies the second third of the head. The basal half of the soft dorsal, anal, and of the caudal fin covered with minute scales. This fish, of which a single individual was observed in 1845 at Pinang, appears to be the young of *P. nigrum*, from which it merely differs by the yellowish colour of the caudal, pectorals and of the margins of soft dorsal and anal fins.

(3683) *Pristipoma paikeeli*, Cuv. and Val.

Syn. Russell CXXI. Paikeeli.
Pristipoma paikeeli, Cuv. R. A. II. 176 (a.)
Pristipoma paikeeli, Cuv. and Val. V. 259.

Silvery brownish white; abdomen buff; on the back and sides as far as the pectoral fin six parallel longitudinal bands, Van Dyke brown, each enclosed by two black lines; fin-membranes yellowish white, all except the pectoral minutely dotted with brown; the margin of the spinal part of the dorsal black; the upper half of the soft part, and the posterior margin of the caudal blackish. Iris golden. D 12/15, C $17\frac{2}{3}$, A 3/9, V 1/5, P 17, Br. VII. Inhabits *Sea of Pinang*, Madras, Vizagapatam. Total length: 6 inch. The figure of Russell represents the dorsal spines much too slender, and the caudal fin too deeply cleft. It is also defective in not representing the minute scales half covering the membrane of the dorsal rays, of the caudal, anal and of the ventrals. A single individual observed at Pinang in 1845, had nine anal rays, (the last one double.)

(3684) *Pristipoma caripa*, Cuvier.

Syn. Anthias maculatus, Bloch. Pl. 326. Fig. 2?
Lutjan tacheté, Lacépède IV. 239.
Russell CXXIV. Caripe.
Pristipoma caripa Cuv. R. A. II. 176.
Pristipoma caripa, Cuv. and Val. V. 261.

Head above and back brownish black, sides silvery brownish white: cheeks and abdomen silvery white, bluish on the opercles; over the infraorbitals an oblique blackish band, edging the orbit; a second from the occiput, edging the margin of the preopercle and the opercle; a third in front of the dorsal to just beneath the lateral line; three or four blackish spots along the back, three larger, placed in quincunx towards the former, along the lateral line; membrane of dorsal spines hemi-transparent, edged and minutely dotted with black, and with a large black spot between the 4th, 5th, 6th, 7th and 8th spine; upper half of the soft dorsal minutely dotted with black, and with a small indistinct blackish spot in front of the six anterior rays; the other fins pale yellowish white; the membrane of the caudal and anal minutely dotted with brown. Iris golden. D 12/14, C $17\frac{2}{7}$, A 3/7, V 1/5, P 16 or 17, Br. VII. Inhabits *Sea of Pinang*, Batavia, Coromandel, Malabar. Total length: 5 inch. Two individuals together were observed in 1845 at Pinang, where the fishermen asserted the species to be very seldom seen, and never of large size.

(3685) *Pristipoma auritum*, Cuv. and Val.

Syn. Pristipoma auritum, Cuv. and Val. V. 263.

Upper part of the muzzle dark brown, of the rest of the head the upper half of the opercle and of the lax gill-membrane and the cheeks light brownish grey with silvery reflections; preopercle, lower half of opercle and of the gill-membrane silvery yellowish-white, minutely dotted with brown; back and upper part of the sides light greyish green, lower part of the latter and abdomen yellowish white; the scales of the occiput and upper half of the body with a reddish brown spot at the root, reflecting lilac and forming irregular series or longitudinal lines; the scales of the lower half of the sides silvery at the

root, and minutely dotted with brown; fin-membranes whitish transparent, minutely dotted with brown, rays yellowish white; between the dorsal spines numerous reddish brown round or elongated spots, forming from 3 to 6 oblique series; the margin of the membrane black; between the dorsal rays some rounded smaller spots, forming 4 transversal lines. Iris golden. D 12/14, C 17½, A 3/7 or 8, V 1/5, P 17, Br. VII. Inhabits *Sea of Penang*, Siam, Total length: 1 foot 8⅝ inch. The eye occupies the third seventh of the length of the head when the muzzle is protracted; the length of the opercle is little less than one half of that of the head; it is convex and projects backwards above the anterior half of the pectoral; the mouth is comparatively very small with few teeth; the external series under the symphysis of the upper jaw is a little stronger than the rest; those few in the lower jaw nearest the angle of the mouth are the largest, nearly conical. The length of the second anal spine equals that of the fourth dorsal, the longest, and it is nearly ¾ of the vertical diameter of the body immediately above it. The anterior surface of all the spines is longitudinally furrowed. The caudal fin is covered almost throughout with minute rough scales, so as entirely to hide the short accessory rays; the membrane of the ventrals is scaly; the rest naked. The fish but rarely occurs at Pinang, where it is highly valued on account of its excellent flavour and firmness of flesh. Of four at different times examined, the smallest measured 1 foot 5 inches in length: in external characters all resembled each other except in the number of anal rays, varying from 7 to 8, the last one being double. M.M. Cuvier and Valenciennes describe the specimen discovered by Dr. Finlayson in Siam, with 11 dorsal spines, whereas those from the sea of Pinang present 12. In other characters the latter so perfectly agree with the description, that their identity appears to admit of no doubt.

Genus PLECTORHYNCHUS, *Lacepede*, 1801. (Diagramma, *Cuvier* 1817.) Two minute pores under the symphysis, and two fossets on each branch of the lower jaw; preopercle toothed; lips folded and turned back.

(3686) ***Plectorhynchus Blochii***, (Cuvier & Val.)

Syn. Anthias diagramma, Bloch, Pl. 320.
Sparus diagramma, Shaw, IV. 440, Pl, 65.
Diagramma blochii, Cuvier and Valenciennes, V. 312.

Young. Ground-colour of the head, cheeks, opercles and upper half of the body bright orange, lower half yellowish white; from between the eyes a longitudinal brown band following the back, continuing above the base of the soft dorsal fin; a second from the muzzle above the orbit, dividing in two portions which again unite above the middle of the pectoral fin, and continue straight to the posterior part of the soft dorsal; a third, the broadest, from the eye straight to the root of the caudal; a fourth under and following the course of the latter; a fifth and sixth of lighter brown, from the muzzle to the posterior part of the abdomen; a seventh similar from the gill-opening to the posterior part of the root of the anal fin. The margin of the dorsal membrane black, base and upper part orange, intermediate part milk white; between the root of the third and fourth dorsal spine a black spot; from the point of the second to the base of the eighth spine a broad oblique black band, continuing straight to the middle of the soft dorsal, where it unites with the first band of the body, and thus continues to the posterior part of the fin; caudal orange with scattered irregular black spots; anal and ventrals greyish, posterior part black; pectorals orange with a black band across the root, the centre and the point. Iris golden orange, D. 10/23, C 17½, A 3/7, V 1/5, P 17 Br. VII. Inhabits *Sea of Penang*, Southern coast of Ceylon, Total length: 5⅜ inches. As observed by M.M. Cuvier and Valenciennes, this species differs from *Plectorhynchus lineatus*, [Syn. Seba III. XXVII. Fig. 18,—*Perca diagramma*, Linne, Syst. 1319.—*Anthias diagramma*, Bloch, 101. *Pl.* 9.—*Sciæna lineata*, Lin. Mus. A. F. I. 66.—*Perca lineata*, Linne, Syst. 1310.—*Grammistes lineatus*, Bloch, S. 182.—*Diagramma lineatum*, Cuv. and Val. V. 309,] in the greater length of the second, third and fourth dorsal spines, which equals or even slightly exceeds one half the greatest vertical diameter of the body, and in the comparative shortness of the anterior dorsal spine, which is one third of the length of the second. The first anal spine scarcely exceeds one fourth of the second, which, as well as the third, equals the length of the tenth dorsal spine, and slightly exceeds one third of the greatest vertical diameter of the body. The number of fin rays given by M. M. Cuvier and Valenciennes: D 12/16? A 2/7, appears to be incorrect. In fresh state the prevailing, or ground colours of the fish are orange and yellowish white. In the absence of a detailed description of *Bodian cuvier*, Bennett, (*Fishes of Ceylon*, 13,) the species cannot be determined. If the relative proportions of the dorsal spines as represented in the figure, are correct, the fish would appear to be *P. lineatus*. A single individual was observed at Pinang in 1845.

(3687) ***Plectorhynchus Balteatus***. (Kuhl and Van Hasselt.)

Syn. Diagramma balteatum, K and V. H.Cuv. and Val. V. 316.

Bright yellow and black striped; upper part of the back and sides black: a bright yellow narrow longitudinal band from the occiput to the commencement of the soft dorsal fin, sending a short

vertical portion to the third dorsal spine; a second yellow broader band from above the orbit straight over the posterior part of the soft dorsal; next a black band from the muzzle, through the eye, across the cheek and opercle, straight to the caudal over which it continues; next a yellow band, bordered beneath by a pale bluish black, following the abdomen to the caudal; cheeks and lower half of opercles yellow washed with black; abdomen yellow. Dorsal spines black, the membrane between the three anterior spines yellow, the rest black; the soft part of the dorsal yellow with a black margin, beneath which a broad yellow longitudinal band, next a black, but the lower half of the six or seven posterior rays, yellow, in continuation of the second yellow band of the body. Caudal fin yellow with a broad black margin, and longitudinally divided by a continuation of the central black band of the body. Anal yellow, lower half as far as the fourth ray black. Membrane, spine and three first rays of ventrals black; the rest yellow. Pectorals white. On the centre of the whitish lips a black spot. Iris yellow with a transversal black bar. D 10/23, C 17, A 3/7, V 1/5, P 16, Br. VII. Inhabits *Sea of Singapore*, Java. Total length: 3⅝ inch. The head is contained 4⅔ times in the total length; the eye is situated a little in front of the second third of the head; its diameter is a little less than one third of the length of the head. The greatest vertical diameter of the body is ⅓ of the length, the caudal fin not included. The first dorsal spine is ⅓ of the second, the longest, which slightly exceeds ¾ of the greatest vertical diameter of the body; the third is a little shorter, the fourth equals half the depth of the body; the rest gradually decrease, the tenth equalling the first. The second anal spine is remarkably short and slender, its length scarcely exceeding the first dorsal, the second anal is but little shorter and slenderer than the first. The preopercle is very finely toothed; the opercles terminate in three small membranous points. The caudal fin is nearly rhombic, its length slightly exceeding ⅕ of the total. The pectorals are the shortest fins, their length being contained 6½ times in the total. The intestinal canal is simple, about ⅘ of the total length of the fish; the stomach is elongated pyriform, the coats thickened: it contained minute shells. There are 5 cœcopyloric appendages, their length is nearly one half of the intestinal canal. The air-vessel is elongated triangular, its length about one third of the total; from the sides of both its extremities proceed two lateral short, pointed processes, and six equidistant, shorter ones from each side; its colour is white. A few individuals (the one described the largest), were observed at Singapore in June 1840.

Genus LOBOTES, *Cuvier*, 1829. Muzzle short; lower jaw prominent; preopercle strongly toothed; the elongated rounded soft portion of the dorsal and anal fin, and the caudal giving the posterior part of the body a trilobate appearance; towards the symphysis of the lower jaw four groups of very minute pores. Branchiostegous rays six.

(3688) *Lobotes erate*, Cuvier and Val.

Syn. Lobotes erate, Cuv. and Val. V. 322.
Lobotes farkarii Cuv. and Val. V. 325, (*Young?*)
Lobotes erate Bleeker: Verh. Bat. Gen. XXII. 4.
Ikan batu or Ikan pichat briuk, of the Malays.

Young. Head and body blackish brown, light reddish brown, or brownish green, either uniformly or with large blotches of a lighter or darker shade; soft portion of dorsal and anal fin like the body, membrane black; caudal like the body, black towards the yellowish white margin, membrane of the dorsal and anal spines and ventral brownish or greenish grey, tinged with orange; pectorals yellowish white. *Adult.* Brownish lilac or mulberry coloured, either uniformly, or with large blotches of silvery grey; the scales either of the ground colour with silvery grey edge, or vice versa; pectorals yellowish white; soft portion of dorsal and anal, and the caudal like the body, their terminal half bluish or greenish black; membrane of dorsal and anal spines light brown or grey marbled with blackish; ventrals dark bluish grey; throat, inter and preopercle silvery grey. Iris silvery of the ground colour of the body. D 12/15, C 17⅔, A 3/12 or 11, V 1/5, P 15 or 16, Br. VI. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Java, Madura, Malabar, Ceylon, Bay of Bengal, Estuaries of the Ganges. Total length: 2 feet 5 inch. The young differs from the adult in having the margin of the caudal fin or its posterior third, yellowish white, and in having comparatively fewer but much larger teeth or spines on the margin of the preopercle, particularly towards the rounded angle. As the latter is the principal distinguishing character assigned to *L. farkarii*, Cuv. and Val. it is probable that Colonel Farquhar's drawing, upon which the description is founded represents a young individual of *L. erate*. Single individuals weighing upwards of 15 lbs., occur at Pinang at all seasons, and are dried by the natives. The air-vessel is very large, about ⅓ of the total length, silvery white and of a lanceolate shape. It is excessively thin, and so firmly adhering to the back, that but a small part can be removed. The isinglass is by the Chinese dealers considered to be of good quality, but the small quantity procurable renders the fish less valuable in this respect.

Genus SCOLOPSIS, *Cuvier*, 1817. (Scolopsides, *Telfair*, 1830.) The second infraorbital bone terminating in a rounded lobe

generally toothed, with a backwards directed spine at the angle adjoining the orbit; third infraorbital with a forwards directed spine, in some hid in the skin, crossing the former; preopercle toothed; submaxillary pores either absent or very minute; body oval or oblong with large scales; dorsal fin single; mouth moderate; teeth velvety; branchiostegous rays five.

(3689) *Scolopsis aurata*, (Mungo Park).

Syn. Perca aurata, Mungo Park: Tr. Linn. Soc. III. 35.
Anthias vosmori Bloch, Pl. 321.
Lutjanus vosmeri, Lacepede, IV. 213.
Lutjan galon-d'or, Lacep. IV. 216.
Pomacentrus enneadactylus, Lacep. IV. 505, 508.
Scolopsides vosmeri, Cuv. R. A. II. 178(n.)
Scolopsis argyrosomus Khul and Van Hasselt, Cuv. and Val. V. 333.
Scolopsides vosmeri, Cuv. and Val. V. 333.

Head above red; back pale bluish green; sides light red with two indistinct mother-of-pearl coloured longitudinal bands above the lateral line, beneath which a third broader and distincter, terminating opposite the soft dorsal fin; cheeks, opercles and abdomen reddish white; infraorbitals greenish golden; all the scales, the infraorbitals, preopercle and opercle with vermilion edges; membrane of dorsal, anal and ventrals whitish transparent, spines and rays vermilion; caudal and pectoral membrane and rays pale vermilion. Iris reddish golden. D 10/9, C 17½, A 3/7 or 8 V 1/5 P 19, Br. V. Inhabits *Sea of Pinang*, Java, Sumatra. Total length: 7⅝ inch. The eye occupies the second third of the length of the head, which, when the muzzle is protracted, is ¼ of the total length. The greatest vertical diameter of the body is contained about 2½ times in the total length; the series of scales forming the lateral line are much smaller than the rest and of a triangular shape; the upper lobe of the caudal is somewhat longer than the inferior: the length of the anterior anal spine is one half of the second, which is as long as the pectoral spine, but much thicker. The cheeks are concave, and the ascending margin of the preopercle is salient, diverging from the opercle, its teeth distant, bent outwards, but generally pointing backwards. Most of the teeth have at the base a minute downwards pointed spine, which may be perceived by passing a finger from below upwards along the margin. The spine of the first infraorbital is long, bayonet-shaped; beneath it appear two or three smaller; these, the margin of the infraorbitals, preopercle, opercle, the spines and rays of the dorsal, anal and ventral fins, as well as the upper and lower margin of the caudal appear as if they were lackered with vermillion. Two individuals of nearly equal length were observed at Pinang in May and July 1845.

Fam. ANABANTIDÆ.

Genus ANABAS, Cuvier, 1817. Head rounded, broad; muzzle very short, obtuse, more or less depressed; the eye near the muzzle; mouth small; velvety teeth in both jaws; a small transversal band of similar teeth on the anterior, and a few on the posterior part of vomer between the third upper pharyngeals; margins of opercle, subopercle and interopercle strongly toothed; branchiostegous rays six.

(3690) *Anabas scandens*, (Daldorf.)

Harooan of Malays.

Adult. Head above and back dark green, lighter on the sides, abdomen greenish silvery; the membrane between the two largest opercular spines black, forming a rounded spot; dorsal and anal spines and membranes pale greenish lilac, minutely dotted with brown; soft part of dorsal and anal, as well as caudal fin greenish grey. Iris narrow golden round the pupil; the rest golden brown, amber, or pale crimson; the upper half of the orbital margin green bronze. *Young.* Body and the single fins of much lighter colour: at the centre of the root of the caudal a large round black spot; ventral and pectoral rays reddish yellow or pale orange, their membranes transparent whitish. D 18 or 19/9 or 10, C 16⅔, A 10/10 or 11, V 1/5, P 15, Br. VI. Inhabits *Fresh water and estuaries Malayan Peninsula and Islands*, fresh water and estuaries Chusan, Celebes, Java, Madura, Sumatra, Burmah, Tenasserim, Bengal, Assam, Coromandel, Philippines. Total length: 7 inch. At Pinang and Singapore this species is less numerous than in Bengal, and in the former localities large individuals are of comparatively rare occurrence.

The Malayan individuals agree with the Bengal ones in most of the external characters: the length of the head is $\frac{1}{3}$ of the body, the caudal fin not included; the diameter of the eye is $\frac{1}{3}$ of the length of the head. But the caudal fin is comparatively longer varying from $\frac{1}{4}$ to $\frac{1}{5}$ less than the length of the head; the dorsal and anal spines are longer, the ventral rays reach the first anal spine; the greatest vertical diameter of the body varies from $\frac{1}{3}$ to somewhat less than $\frac{1}{4}$ of the total length. Individuals taken in Bengal have the caudal fin $\frac{2}{3}$ of the length of the head; the greatest vertical diameter of the body slightly exceeds the length of the head. The colours are slightly different and the number of fin rays are, D 16 or 17/9 or 10, A 10 or 11/10. In the Malayan countries the fish is eaten by the poorer classes, who, however, attribute to it neither the medicinal qualities nor the climbing propensities, for which it is famed by the natives of Bengal.

Genus MACROPODUS, *Lacepede*, 1820. Velvety teeth in both jaws, with an external series of longer, distant, recurved teeth; margins of infraorbitals and opercles externally smooth: lateral line, when present, interrupted; dorsal and anal rays undivided; dorsal fin of less extent than anal; first ventral and some of the posterior and anal rays elongated, filamentous.

(3691) *Macropodus puguax*, Cantor.

Plate II. Figs. 1, 2, 3.

Head above and back pale brownish or olive grey, lighter on the opercles, sides and abdomen; from between the eyes along the back 8 to 11 blackish vertical bands, reaching the abdomen; along the sides 5 or 6 longitudinal silvery lines, produced by a silvery dot on each of scale; from the angle of the mouth, through the iris to the termination of the opercle a horizontal black band; lips, chin, and throat blackish blue spreading as a horizontal band over the lower part of the side of the head to the gill-opening; dorsal, caudal and ventral membranes pale reddish hemitransparent; margin of the dorsal and the filamentous anterior ventral ray pale golden or silvery green; anal membrane pale Indian red, lower margin silvery bluish or greenish; rays blackish; pectorals whitish transparent. Iris narrow, golden; the half below the black transversal band carmine; the half above the band golden, and near the orbit dark olive. D 1/8 or 9, C 13½, A 2/25 or 26, V 1/5, P 13, Br. VI. Inhabits *Fresh water*, *Pinang*, *Malayan Peninsula*. Total length: 3⅜ inch. The head is much depressed, and far broader than the body, which is gradually compressed towards the caudal fin. The profile of the back is slightly arched, the highest part being at the dorsal spine; the abdominal profile is less arched than the former. The length of the head is $\frac{1}{3}$, or slightly more, of the length of the body, the caudal not included; the depth at the occiput $\frac{2}{3}$ of the length of the head. The eyes are prominent, occupying the second fourth, and bordering on the profile. Their distance across the forehead is nearly double the diameter. The mouth is semicircular, moderate; the angle is in front of the orbit. The posterior opening of the nostrils is situated close to the orbit; the anterior is provided with a small fleshy tube. The tongue is free, fleshy and very pointed. Behind the velvety teeth of the upper jaw appear successively three semicircular membranous folds, of which the posterior is papillular on the margin, which thus appears as if studded with a second series of minute teeth. The head is everywhere covered with large rounded scales like the rest of the body, but the slightly protractile jaws are naked; the posterior part of each branch of the lower jaw is covered by a single large oval scale. The greatest vertical diameter of the body, at the dorsal spine, is in some individuals $\frac{3}{4}$ of, in others equal the length of the head. The vertical diameter at the root of the caudal fin varies from 5½ to $\frac{1}{6}$ of the length of the body. The dorsal fin commences a little behind the posterior half of the body; the rays gradually increase towards the fifth, the longest; the extent of the base is from $\frac{1}{3}$ to $\frac{1}{2}$ of the length of the body; the distance from the last ray to the caudal is $\frac{1}{4}$ of the length of the body. The caudal is very broad lanceolate; the two central rays are the longest, in some individuals $\frac{1}{5}$ of the entire length of the fish, but frequently less. The length of the anterior filamentous ventral ray rarely exceeds that of the head. The pectorals are rounded, their length but slightly exceeds $\frac{1}{2}$ of the head. Opposite their posterior half is situated the anus, immediately behind which the anal fin commences. The rays of the latter gradually increase in length to the twenty-third or fourth, which are sometimes elongated beyond the point of the caudal fin. The extent of the scaly base of the anal equals $\frac{1}{2}$ of the length of the body. No lateral line appears, but on the series it would occupy if present, some of the anterior scales have each a central rounded depression, which, however, also appears of single scales near the back. Three series lower down, on the posterior half of the sides, commences sometimes a row of similar depressions, which then continue to the caudal fin. The scales are rather large, higher than long; the anterior margin is straight with 21 striæ, the posterior round, ciliate; a line from the gill-opening to the caudal fin contains 32; the greatest vertical diameter presents 10. Of the six branchiostegous rays the upper one is longer and broader than the rest; the fifth and sixth are rounded, setaceous. Œsophagus is voluminous, short, suddenly widening into the rounded capacious stomach. The intestinal canal is doubled upon itself, about $\frac{1}{7}$ of the length of the fish. Neither cœcopyloric appendages nor air-vessel

appear. The liver is elongated of a reddish yellow. The skeleton has 28 vertebræ of which 10 are abdominal. The branchial labyrinth (Plate II. Fig. 2.) is still more reduced than it is in *Macropodus viridi-auratus*, Lacep. and almost as simple as in *Spirobranchus capensis*, Cuv. (Cuv. Val. VII. 392, Pls. 200 and 205.). It consists of a single backwards bent lamina, and a very small posterior rudimentary one. At the foot of the hills at Pinang this species is numerous in rivulets. Like the rest of the family it is capable of living for sometime out of water. The Siamese inhabitants with whom this species is a great favourite, keep these fishes in jars with water, where the larva of musquitoes is their food, and denominate them "*Pla kat*," *Pla*, fish; *kat*, a fighter. The Variety is noticed by Lieut. Colonel Jas. Low. i. e. the fighting fish, although they live peaceably together. The real fish however, the exhibition of whose combats is a popular amusement with the Siamese, appears to be a variety of the present species, produced by artificial means, like the varieties of the golden carp of China.

(3692) *Macropodus pugnax*, *Var.* Plate II. Fig. 4.

Pla kat of the Siamese.

Head above and back dark greenish olive, lighter on the sides, the lower part of which and the abdomen deep blood red; all the scales edged with black; a black longitudinal band from the eye to behind the dorsal fin, a second from the nostrils, through the iris to the root of the caudal; a third from below the eye obliquely downwards to the gill-opening; dorsal membrane silvery greenish brown with numerous black undulating lines, vertically intersecting the black rays; caudal membrane golden green, the rays bright blood red, the fin edged with black; anal membrane bright blood red as far as the posterior 4 or 5 rays, the rest as well as the lower margin silvery light green or sky-blue, the rays black; ventral spine and rays black, the first ray terminating in a silvery filament; the membrane between the first, second and third ray bright blood red, the rest black; branchiostegous rays and their very wide membrane black; pectorals white, transparent. Iris pale reddish golden with a bluish black spot in the centre of the lower half. The number of fin rays, and other external characters are the same as in the species, but the colours and the length of the dorsal, caudal, anal and ventral fins are individually varying. The branchiostegous membrane is remarkably wide and lax. When the fish is in a state of quiet with the fins at rest, the dull colours present nothing remarkable. But if two are brought within sight of each other, or if one sees its own image in a looking glass, the little creature becomes suddenly excited, the raised fins and the whole body shine with metallic colours of dazzling beauty, while the projected gill membrane, waving like a black frill round the throat, adds something grotesque to the general appearance. In this state it makes repeated darts at its real or reflected antagonist. But both when taken out of each other's sight, instantly become quiet. The description was drawn up in 1844 at Singapore, where a gentleman had been presented with several by the King of Siam. They were kept singly in glasses with water, fed with larvæ of musquitoes, and had thus lived for many months. The Siamese are as infatuated with the combats of these fishes as the Malays are with their cock fights, and stake considerable sums, and sometimes their own persons and their families. The license of exhibiting fish fights is farmed, and affords a considerable annual revenue to the King of Siam.

Genus OSPHROMENUS, (*Commerson*) *Cuvier*, 1829 (OSPHRONEMUS [*Comm.*] *Lacepede*, 1800.) Differs from *Polyacanthus*, Kuhl and Van Hasselt, by the shorter extent of the dorsal fin, by the more complicated labyrinthform (superbranchial) organ, by the very elongated, setaceous first ventral ray, and by the toothed margin of the infraorbitals. In the young, the margin of pre- and interopercle are toothed.

(3693) *Osphromenus olfax*, Commerson.

Osphromenus olfax, Richardson: Rep. 1845, 251.
Osphronemus olfax, Bleeker: Verh. Bat. Gen. XXII. 4.
Ikan gorammi, of the Malays.

Young. Head above and back dark brown or olive, lighter greenish on the sides of the head and body to a little above or below the lateral line; lower parts of the sides of head and body, and abdomen silvery brownish or reddish buff; from the occiput to the caudal 7 to 9 oblique blackish bands; at the root of the pectorals, and in the penultimate lateral band, a little in front of the termination of the anal, a black spot; pectorals and posterior half of ventrals whitish, the rest and the membranes of the other fins closely and minutely dotted with brown; spines and rays brownish grey. *Adult.* Head, back and upper part of the sides reddish or greenish dark brown; opercles and lower half of the sides impure yel-

lowish white; lateral bands very indistinct; fins greyish brown, ventrals and pectorals paler than the rest; iris reddish golden with scattered black spots. D 13/1; 10/10; 13/12; C 16½, A 9/28; 10/30; 11/19; 12/20; V 1/5, P 15, Br. VI. Inhabits (*Naturalised*) *Fresh water, Pinang, Malacca*, China, Java, Madura, (*Naturalised*) Isle of France, Cayenne. Total length: 1 foot 6 inch. The very young individuals differ from the adult not only in colour, but also in having the head more elongated: its length being from 2½ to 2⅔ in that of the body, the caudal not included. In the adult the head is 3¼ in the body alone, the toothed margin of the pre- and inter-opercle becomes smooth, and the first ventral ray is comparatively shorter than in the young, in which it sometimes reaches the caudal fin. Both at Pinang and at Malacca this fish has been successfully naturalised though in the former place it is not numerous, but confined to a few ponds. They become tame so as to appear on the approach of their feeder, and will rise to flies, beetles, and certain flowers, particularly a large *Hibiscus*. Among themselves they are pugnacious. Many years ago several living ones were imported, and placed in a tank in the Calcutta Botanical Gardens, where they appeared to thrive. Little care, however, having been bestowed on their preservation, but a solitary one survived in 1841.

Genus TRICHOPODUS, *Lacepede*, 1809. Scarcely differs from *Osphromenus* but by a more convex forehead, and by a dorsal fin of less extent. Although to these differences may be added a less complicated labyrinth-form organ, and five branchiostegous rays, the genus rests but on slender characters.

(3694) *Trichopodus trichopterus*, (Pallas.) Plate II. Fig. 5. (Head.)

SYN. Sparus Koelreuter. Nov. Comm. Petrop. IX. P. 452 Pl. 9. Fig. 1.

Trichopus maculatus, Swainson. II. 235.
Trichopus trichopterus, Bleeker; Verh. Batav. Gen. XXII. 4.

Head above, back and sides to a little below the lateral line brownish olive, each scale of the latter with a sky-blue or verdigris rectangular spot; cheeks and opercles silvery light blue with lilac reflection; sides below the lateral line silvery light blue, abdomen silvery reddish lilac, all the scales iridescent, edged with reddish brown forming an irregular network; from the angle of the mouth through the iris, below the silvery lateral line to the root of the caudal a black zig-zag band, widening at the termination into a large spot, and in some individuals a similar in the centre part of the band; dorsal spines and rays whitish grey, their membrane dark grey with numerous white rounded spots; caudal membrane and rays like the dorsal; anal spines carmine, their membrane and rays whitish, each ray terminating in a short silvery filament; ventral spine, membrane and four rays whitish, the anterior elongated ray carmine; pectoral pale carmine at the root, the rest white transparent. Iris narrow golden round the pupil, lower half sky blue, upper half above the black bar golden brown. D 6/9; 7/8: 7/9; 7/10, C 16½, A 10/34; 12/29; 13/29; 14/28, V 1/5, P 9, Br. V. Inhabits *Fresh water, Pinang, Malayan Peninsula*, Moluccas, Madura, Java. Total length: 4⅜ inch. Like all the species of this family, the present is liable to considerable individual variations of colours, number of fin rays and proportions. Thus M.M. Cuvier and Valenciennes count: D 5/8, C 16, A 11/35 or 36, V 5, P 14, Br. IV. and ask with doubt if the species be different which Bloch characterises: D 7/7, C 16, A 1/33, V 3, P 10, Br. IV. With regard to the number of branchiostegous rays, it is *five* on each side; the superior is the longest and broadest, the rest gradually decrease in length and breadth. They are difficult to count as the second is completely hid under the first, and the fourth and fifth are very thin, setaceous, and may thus easily be mistaken for a single one. The ventral spine is very short, and thick, but so firmly adhering to the root of the first elongated ray, that it easily escapes observation. The short, gradually decreasing 2d, 3d, 4th, and 5th ray are divided, but the latter is frequently undivided. The length of the head varies in individuals of equal length from 3½ to 3⅓ in that the body, the caudal fin not included. The latter is a little shorter than the head, the vertical diameter of which at the occiput, equals the length. The diameter of the eyes is 3½ times in the length of the head; their distance across the forehead is 1½ diameter. The anterior smaller opening of the nostrils has a short membrany tube. The mouth is small and rendered more so as the lower jaw forms a much smaller half circle than the upper. Both have a narrow band of velvety teeth. The tongue is small, fleshy, and its margin completely adhering to the floor of the mouth. The greatest vertical diameter of the body at the fourth dorsal spine varies from 2⅖ to 2⅔ in the length of the body, the caudal fin not included. The distance from the last dorsal fin to the upper caudal appears to be constantly equal the length of the head. The longest dorsal, caudal and anal rays seldom exceed the length of the head, but are frequently a little shorter. The first ventral ray in some

reaches the termination of the anal, in others beyond that of the caudal. The anal rays are either all undivided or a few of the posterior are divided, and the last connected to the caudal. The length of the pectoral is ¾ of that of the head. The lateral line consists on each scale of a central transversal tube, above and below which appears a short elongated furrow. A straight line from the gill-opening to the root of the caudal contains from 44 to 46 scales; a vertical at the deepest part of the body from 2[illegible] to 25. The lower margin of the infraorbitals and of the preopercle are closely and rather strongly toothed. The stomach is rounded, contracted in the middle, and as well as the spirally twisted intestines almost entirely hid by the large light brown liver. There are two rather long cœcopyloric appendages. The gall-bladder is rather large, the spleen small. Between the vertebral column and the abdominal cavity appears a very short air-vessel, silvery like the peritoneum, but much thinner. The intestinal canal is nearly double the length of the fish. The labyrinth-form organ (Plate II. Fig. 5,) is less complicated than in *Osphromenus olfax*: it consists of three laminæ of which the central is the largest, entirely hiding the third, the inner one. Like the rest of the family, this species is capable of sustaining life out of water, particularly if kept in wetted fresh leaves, or occasionally sprinkled with water. At Pinang it is numerous in streamlets and ponds, where it is eaten by the poorest classes. The exquisite beauty of the metallic irridescent colours make these fishes acquisitions in garden tanks. Like *Osphromenus olfax* they are very pugnacious among themselves. A second species of *Trichopodus* has been discovered by Mr. Campbell, Superintendant of Darjeeling, in the rivers at the Sikkim passes on the northern frontier of Bengal. An incorrect and defective description and figure have been published by Mr. McClelland, who imagining the fish to belong to the Family of *Chætodontidæ*, and the genus to be new, denominated it *Ctenobs nobilis*. Cal. Journ. Nat. Hist. V. 281, Pl. 21, Fig. 1.

Genus OPHIOCEPHALUS, *Bloch-Schneider*, 1801. With labyrinth-form superbranchial organ; fins without spines, the ventrals commencing with a divided or undivided, joined ray; dorsal occupying nearly the whole length of the back; caudal rounded; lateral line uninterrupted; head depressed, covered with polygonal scales; both jaws, vomer and palatal bones with velvety, or card-like teeth, among which generally some longer than the rest; body elongated, almost cylindrical. Branchiostegous rays five.

(3695) *Ophiocephalus striatus*, Bloch.

Ikan haruan of the Malays.

Head above and back greenish olive with indistinct clouded black spots; cheeks, opercles and sides to a little beneath the lateral line lighter with metallic lustre; throat, abdomen and lower part of the head and sides white; from the angle of the mouth a short metallic-olive oblique line, and on the throat a few distant dark spots; lower part of sides with a number of backwards directed oblique, blackish lines, the intervals between which pale salmon-coloured; dorsal membrane minutely dotted with brown so as to produce oblique brownish lines, between which, at the base, appear some rounded whitish spots; caudal pale brownish with indistinct light concentric lines; upper half of anal white with oblique brown lines; lower half blackish brown; ventrals white with indistinct blackish spots; pectorals transparent whitish, minutely dotted with brown along the margins of the rays. Iris amber-coloured, orange or reddish golden round the pupil, the rest golden olive, clouded with black. D 41, 42 or 43, C 14½, A 25, 26, or 27, V 6, P 16 or 17, Br. V. Inhabits *Fresh water and estuaries, Malayan Peninsula and Islands*, Manilla, Celebes, Tenasserim, Rangoon, Irawaddy, Ganges, Bengal, Barrampootr, Goalparah, Coromandel, Malabar, Hindoostan. Total length: 2 feet. The length of the head is from 3½ to 3⅔ in the total; (it is ⅓ of the distance from the muzzle to the last dorsal ray;) the height at the occiput is 2⅓ in the length. The horizontal diameter of the eyes slightly exceeds ⅛ of the length of the head; their distance across the forehead equals two such diameters. The vertical diameter at the first dorsal ray is ½ of the length of the head. The anterior part of the lateral line gradually descends towards the commencement of the second third of the dorsal, from whence it proceeds straight to the root of the caudal. The line is marked on each scale by a short central tube, which bifurcates. The number of component scales vary from 60 to 62. An oblique series from the anus consists of 18 to 20 scales. In these and other characters the Malayan individuals exactly correspond to *O. striatus*, Bloch, as described by M.M. Cuvier and Valenciennes. Individuals of *O. wrahl?* apud Buchanan Hamilton, (*Sol.*)

taken in the vicinity of Calcutta, differ but slightly in colours, and in presenting from 43 to 46 dorsal, and from 26 to 28 anal rays. *O. chena*, Buch. Ham. offers the same number of rays as the latter, and appears but to be another variety, probably as Buchanan suggests, the identical one which Russell figured No. CLXII. *Muttah*. In the Malayan countries, the fish is as numerous as in Bengal, and it is also there eaten by the natives.

Fam. MUGILISIDÆ.

Genus MUGIL, (*Artedi,*) *Linne*, 1748. Body nearly cylindrical, covered with large scales; two dorsal fins widely separated: the anterior spinous, the posterior with one or two spines, the rest rays; ventrals behind the pectorals; centre of the lower jaw with an elongated angular point, corresponding to a notch in the upper jaw; teeth minute. Branchiostegous rays six.

(3696) *Mugil parmatus*, Cantor. *Young?* Head above and back pale brownish olive; cheeks and upper half of the sides silvery greenish grey; lower half of the sides and abdomen silvery white; on the upper part of preopercle a triangular bluish black spot, behind which an indistinct amber-coloured spot; the rest of preopercle and opercle pale silvery blue, faintly vermiculated with brown; dorsal and caudal membranes pale grey, minutely dotted with brown; the rest of the fins white. Iris silvery grey. D 4—1/8, C 14 ½, A 3/9, V 1/5, P 14, Br. VI. Inhabits *Sea of Penang*. Total length 4⅝ inch. The length of the head is 4⅔ in the total, or ¼ of the length of the body, the caudal not included; the height at the occiput ⅖ of the length of the head. The orbit occupies the second fourth of the head; the eye is covered in front and behind by a crescent-shaped adipose lobe; the distance of the orbits across the forehead equals 1½ diameters. On the anterior margin of the infraorbital bone appears a broad angular incision, which receives the angle of the lips; the inferior margin is truncated, minutely toothed; near the upper margin of the infraorbital, below the two small openings of the nostrils, appear two minute pores. The mouth is very small; both jaws have excessively minute setaceous teeth, scarcely projecting beyond the cartilaginous lips. The greatest vertical diameter of the body, in front of the anterior dorsal spine, equals the length of the head; that in front of the caudal fin is ½ of the former. A straight line from the gill-opening to the caudal contains 27 scales, an oblique series 10. The anterior dorsal spine is strong: its length is a little less than ¾ of that of the head; no elongated triangular scale appears at the base of the anterior dorsal, nor of the pectoral. The second dorsal, the caudal and anal fins are half covered with very small scales. The first anal spine is excessively minute. The two central rays of the caudal are but very slightly shorter than the rest. A single individual was observed at Pinang in April 1844. The present greatly resembles *M. grandisquamis*, Cuv. and Val. (XI 103), an African species, remarkable for the great size of its scales. The latter differs in the following particulars. The greatest height is nearly ¼ of the total length; at the occiput the height is ⅓ of the length of the head; at the root of the caudal it is one half of the greatest. It is described as having no teeth.

(3697) *Mugil macrolepidotus*, Ruppell.

Syn. Muge christian, Quoy et Gaimard: Voy. de Freycinet.
Mugil macrolepidotus, Ruppell: Atlas, Fische, p. 140, Taf. 32, Fig. 2.
Mugil macrolepidotus, Cuv. and Val. XI. 134.
Mugil macrolepidotus, Richardson: Report, 1845, 249.

Young. Head above and back pale bluish green; lighter, silvery, on the sides of the head and abdomen; opercle steel blue; on the sides four parallel pale blackish lines; dorsal, caudal, and anal spines, rays, and membranes minutely dotted with black; on the dorsals and anal so closely as to give the marginal half a black appearance; ventrals white, posterior half of the three anterior rays minutely dotted with black; upper ten pectoral rays black, the rest white. Iris silvery. D 4—1/8, C 14½, A 3/8, V 1/5, P 16, Br. VI. Inhabits *Sea of Pinang*, Waigiou, Rawak, Borabora, Vanikolo isles, Malabar, Red Sea, China Seas? Total length: 5 inch. The length of the head is 4⅓ in the total; the height at occiput ⅓ of the length. The diameter of the eyes is 3½ in the length of the head; their distance across the forehead equals two diameters. The anterior margin of the infraorbital bone is arched, so as to receive the angle of the lips and as well as the inferior truncated margin finely toothed. The young has no perceptible teeth; M.M. Cuvier and Valenciennes describe them as short and fine in the adult. The posterior margin of the preopercle has three deep indentations. The vertical diameter in front of the first dorsal spine slightly exceeds ¼ of the total length; that in front of the caudal fin is less than one half of the former. A straight line between the gill-opening and the root of the caudal contains 29 scales; an oblique series in front of the anterior dorsal fin 9. The first dorsal spine is scarcely ⅓ of the length of the head, and less strong than in *M. parmatus*. A single individual was observed at Pinang in August, 1843.

Mugil cephalotus, Bleeker, Verh. Bat. Gen. XII. 5.
Jumpul of the Malayas.

Head above and back lead-coloured tinged with green, lighter silvery on the sides of the head and body as far as the upper margin of the pectoral fins; all the parts below dull silvery white; on the sides five to seven parallel, dark grey longitudinal bands; anterior dorsal fin light bluish grey; posterior and caudal membrane dark grey, rays lighter; anal and ventrals white; pectorals outside white, semi-transparent, inside with a large oblique blackish spot on the anterior half. Iris silvery or mother-of-pearl round the pupil; the rest blackish brown. D 4—1/8, C 14⅗, A 3/9, V 1/5, P 17, Br. VI. Inhabits *Sea of Penang*, *Malayan Peninsula*, *Singapore*, *Lancavy Isles*, Chusan, Macao, Maderia, Coromandel, Bay of Bengal, Gangetic estuaries, Malabar. Total length; 2 ft. The head is much depressed, broad oval, the muzzle being about half the breadth of the occiput. The upper surface is less transversely arched than the lower; both surfaces where they join, form a blunt ridge from behind the eye to the short triangular membranous point in which the opercle terminates. The eye is situated in front of the ridge, occupying the third eighth of the head; its transversal diameter being ⅓ of the length of the head, which is 4½ times in the total, or ¼ of the body, the caudal fin not included. The distance between the eyes across the forehead equals 3¾ diameters. The vertical diameter of the head between the eyes is about ⅓ of the length: at the occiput it is ½. The openings of the nostrils are situated a little above the level of the orbit, along the superior margin of the infraorbital; the posterior, the larger, is transversely oval; the anterior is circular. The infraorbital bone is broad triangular, with the rounded, truncated apex downwards; the latter, as well as the backwards arched anterior margin, is finely but distinctly toothed, and naked, but the rest of the external surface is covered with small scales. The adipose membrane covering the circumference of the eye is of a whitish grey. No such series of pores appear on the lower half of the membrane, as M. Ruppell has observed in *Mugil oür*, Forskal (*not* apud Cuvier and Val.), nor are there any pores under the lower jaw. The lower half of the posterior margin of the preopercle has two large, a little obliquely upwards-directed indentations, and in some the upper half of the margin has two similar ones. *M. oür* as well as *M. cephalus* are according to M. Ruppell distinguished by six pores beneath the lower jaw, and by three not very distinct oblique indentations in the lower margin of the preoperculum. The mouth is horizontal, the angle is opposite the anterior opening of the nostril; the upper jaw projects beyond the lower. The upper mandible is flattened, broad in the centre, tapering towards the angles of the mouth; in the centre is a very small notch. In the upper lip appears a single series of very minute teeth. The symphysis of the lower jaw forms a tubercle under which appears a notch deeper than that of the centre of the upper mandible. The lower lip is more fleshy than the upper, and the margin is bent downwards, so as to form on each side a furrow proceeding from the notch under the symphysis to the angle of the mouth. The teeth of the lower jaw are so excessively minute, few, and distant, that even in large individuals they are imperceptible to the touch, and can only be seen through a lens. In smaller individuals these teeth are absent, or at least confined within the half transparent mandibles, and appear like short seta, bent with the lip, but not projecting beyond it The tongue is fleshy, broad at the root, narrower, rounded at the apex, and raised in a keel in the centre. Along the margin which is fixed to the floor of the mouth, appears a series of rounded or oval patches of velvety teeth. At the root of the central keel is an elongated patch, and close behind the apex two smaller ones of velvety teeth. On each side of the vomer is raised into a tubercle, carrying a transversely placed linear patch of similar teeth. Every part of the head is covered with scales, of which those of the opercle are very large, but in young individuals they are so thin as to make the silvery opercle appear scaleless. The vertical diameter in front of the anterior dorsal spine equals the length of the head minus the diameter of the eye. The anterior dorsal spine equals the distance from the muzzle to the posterior margin of the orbit, or about ½ of the last mentioned vertical diameter. The anterior dorsal fin commences in the centre of the distance between the muzzle and the root of the caudal. The extent of the base equals the length of the anterior spine; from its centre commences an elongated, triangular scale, projecting midway behind the very slender fourth spine, the length of which is ½ of the preceding three. The distance between the anterior and posterior dorsals equals ⅓ of the length of the head, the latter fin commencing opposite the centre of the anal, much nearer the caudal than the anterior dorsal. The anterior ray equal ¼ the length of the head. The distance between the posterior ray and the root of the caudal equals the length of the anterior dorsal spine. The posterior margin of the caudal fin is but slightly furcated, the inferior lobe is a little larger than the upper. The anal fin commences about halfway between the termination of the ventrals and the root of the caudal fin. Its height equals, its extent slightly exceeds the second dorsal. The two anterior spines are so completely covered by

scales, that they escaped the observation of Russell, whose figure (CLXXX.) represents the third much too long: it exceeds but slightly ½ of the anterior ray. The length of the pectoral fin is 7½ in the total, or nearly equal that of the caudal. Above the root of the pectoral appears no trace of an elongated triangular scale, as in some other species, but in the axilla, hidden by the fin, are two elongated oval scales, much smaller than the rest. The ventral fins are a little shorter than the pectorals: the spine is strong and but slightly shorter than the anterior dorsal. At the base of each fin appears an elongated triangular scale, and a similar, but shorter and broader between the two fins; the anterior half of the fifth ray is attached to the abdomen by a membrane. A straight line between the gill-opening and the root of the caudal fin contains from 33 to 35 scales, an oblique series in front of the anterior dorsal 11 or 12. The scales are very large, nearly as broad as long; the anterior margin is straight, but with from 2 to 6 crenulations, produced by a number of radiating lines, varying in number from 3 to 7. The posterior margin is rounded and with excessively minute points, the termination of a very fine concentric net-work on the exposed surface. Each scale is marked by a fine central line, horizontal in most, but pointing obliquely downwards on the scales immediately beneath the root of the pectoral fins. The stomach is composed of two portions: the cardiac into which the short capacious œsophagus opens, terminates in an elongated cylindrical fundus; the pyloric portion is shorter, globular like a large button, and very thick, gizzard-like. The cavity is very small and presents a few coarse longitudinal folds. In several examined, it contained some mud, mixed with green mucus. Pylorus is surrounded by five short but capacious cœcopyloric appendages. The intestinal canal, about 7 times the length of the fish, is folded several times upon itself and firmly enveloped in fat. The gall is rather large, ovoid with a short duct opening close to Pylorus. The liver is moderate, resting across the stomach, with several lobes, of which the longest is attached to duodenum. The spleen is small, elongated, completely hidden by the fat between the folds of the intestines. The abdominal surface of Peritoneum is black, the opposite silvery. The air-vessel is large, elongated, its parietes very thin, pearl-coloured. At Pinang this species occurs, though not numerously, at all seasons, and when newly taken it is highly valued for its excellent flavour. The present is the fish supposed by Russell to be *Mugil cephalus*, Linn. (Vol II. p. 64.) The figure, (CLXXX. *Bontah*,) among other inaccuracies represents the mouth without teeth, and the anal fin with a single, too long spine. The latter, as well as the margins of the scales being entire, (as they in reality appear to the naked eye,) induced Buchanan Hamilton to consider the individuals which he obtained from the estuaries of the Ganges, to be a distinct species, and also he overlooked the minute teeth in the lips. MM. Cuvier and Valenciennes (T. XI.) unite both under the denomination of *M. cephalotus*. They doubt, however, without reason, the correctness of Russell's omitting to figure, and Buchanan to mention, any elongated triangular scale above the pectoral fins, and they believe that the fish is identical with *Mugil our*, Forskal, (*Descr.* p. XIV. No. 109, *Var.*, and characterised: "Labio utroque ciliato, inferiori unicarinato, oculis pinguedine fere obtectis, operculo macula p. p. oblonga obliqua.") Dr. Ruppell, (*Neue Wirbelth, &c. Fische*, p. 131,) observes that if Russell's description of "*Bontah*," as being "without teeth" is correct, the fish cannot be identical with *M. our*, the microscopical teeth of which Forskal expresses by the word "ciliato." It is to be regretted that Dr. Ruppell did not communicate a more detailed description of the fish from the Red Sea, which is most likely Forskal's species, for although Russell happens to be incorrect, the fish he described presents neither the six-pores under the lower jaw, nor the arched series of pores in the adipose membrane, covering the lower part of the eye, which Dr. Ruppell points out as characters distinguishing *M. our*. It is therefore impossible with certainty to determine if the latter is identical with the present species.

(3699) *Mugil cunnesius*, Cuv. and Val.

Syn. Russell CLXXXI. Kunnesee.
Mugil kunnesee, Cuvier R. A. II. 232 (1.)
Mugil cunnesius, Cuv. and Val. XI. 114.
Mugil cunnesius, Ruppell: Neue Wirbelth. Fische, 131.

Young. Head above and back silvery bluish green, lighter, minutely dotted with black on the upper half of the sides; lower half and abdomen silvery white; sides and abdomen with parallel silvery lines, produced by a short line on each scale; cheeks and opercles shining silvery, the latter with steel-blue reflections; fin-membranes white, those of the dorsals and caudal minutely dotted with black, particularly towards their margins, so as to make them appear blackish; in some a black spot at the root of the upper pectoral ray, continued in the axilla as a blackish line. Iris silvery round the pupil, the rest dotted with black. D 4—1/8, C 14 5/4, A 3/9, V 1/5, P 16 or 17, Br. VI. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Moluccas, Bay of Bengal, Coromandel, Malabar, Red Sea. Total length: 6½ inch. The length of the head is ¼ of the body, not including the caudal fin. The height at the occiput is about ⅘ of the length of the head. The eye occupies the second fourth of the head; the diameter, not including the adipose covering, is ⅕ of the head; but the diameter of the orbit is ¼ of the head;

the distance across the forehead is $\frac{1}{2}$ diameter. The infraorbital is triangular, with the apex truncated, slightly rounded and finely toothed; the anterior margin is nearly straight, neither toothed nor notched. The anterior opening of the nostril is minute, circular; the posterior a little larger, transversely oval, both situated along the upper margin of the infraorbital. The mouth is small, the lower jaw but little shorter than the upper; the angle is situated opposite the anterior opening of the nostril. The notch of the upper lip corresponds to the tubercle of the lower, which is notched underneath. There are no teeth perceptible in the lips. On each side of the vomer appears a transversal tubercle. In the young the opercles appear to be scaleless. The vertical diameter in front of the first dorsal spine equals the length of the head. A straight line from the gill-opening to the root of the caudal fin contains 42 or 43 scales; an oblique in front of the anterior dorsal fin 13. Each scale is marked by a central line, horizontal in most, but almost vertical in those immediately below and in front of the pectoral fins. The third dorsal spine is situated at equal distance from the muzzle and the root of the caudal fin. The length of this, as well as of the two preceding spines, exceeds $\frac{1}{2}$ of the vertical diameter of the body beneath them, and it also slightly exceeds the extent of the base of the fin itself. The fourth spine is about $\frac{1}{2}$ of the preceding three. On each side of the base is an elongated scale. The second dorsal fin commences at equal distance from the first dorsal spine and the root of the caudal, opposite the third anal ray; the base nearly equals the length of the first ray. The caudal fin is slightly lunated: the length of the first and fourteenth ray is about $\frac{1}{5}$ of the total length. The length of the pectoral fins is $5\frac{1}{2}$ times in the total; above the root of each appears an elongated scale, formed like a knife-blade with the back towards the upper margin of the fin; its length is nearly $\frac{1}{2}$ of that of the fin. At Pinang young individuals are numerous at all seasons.

(8700) *Mugil borbonicus*, Cuv. and Val.

Mugil borbonicus, Cuv. and Val. XI. 113.

Young. Head above and back bluish green; lighter silvery on the upper half of the sides; lower half abdomen and cheeks silvery white; opercles shining silvery; anterior dorsal fin-membrane transparent minutely dotted with black; first spine blackish; posterior dorsal, caudal, anal and pectoral pale yellow, minutely dotted with black; spine and upper half of the first ray of second dorsal, and the upper, lower, and posterior broad margin of caudal black; at the root of the upper pectoral ray a black spot continued over the anterior half of the inside of the pectoral; ventrals white. Iris silvery round the pupil, blackish green towards the orbit. D 4—1/8, C $14\frac{1}{2}$, A 3/9, V 1/5, P 17, Br. VI. Inhabits *Pinang River*, Bourbon. Total length 6 inch. The length of the head is $\frac{1}{4}$ of the body, the caudal fin not included; the height at occiput $\frac{1}{3}$ of the length. The eye occupies the second fourth of the head; the diameter of the orbit is $\frac{1}{3}$ of the length of the head; the distance between the eyes across the forehead is $\frac{1}{3}$ diameter. The infraorbital is triangular, covered with small scales, and with three pores placed obliquely in the middle of the external surface; the anterior margin is finely toothed, and slightly arched, but becomes a little concave towards the truncated, finely-toothed apex. The superior margin is somewhat angular in the centre, on each side of which appear the openings of the nostrils. The mouth is small, transversal; the angle is situated opposite the posterior opening of the nostril; the lower jaw is but slightly shorter than the upper. There are no visible teeth in the lips; the lower has in the centre a strong tubercle which in front and beneath is deeply furrowed. On each side of the vomer appears a strong transversal ridge. Under each branch of the lower jaw appear three pores. The preopercle is covered with large very thin scales, and has a long transversal incision in the posterior margin, near the angle; the opercle and subopercle are apparently without scales, and brilliantly shining with silver. Nearly all the scales of the occiput are divided lengthwise by a shallow furrow, which on the scales of the body becomes a short longitudinal line. But the scales immediately below the pectoral fin are each marked near the root by a short vertical line. A longitudinal series between the gill-opening and the root of the caudal consists of 39 scales; an oblique in front of the anterior dorsal fin of 14. The vertical diameter in the latter place is $4\frac{1}{2}$ of the total length. The length of the three anterior dorsal spines is about $\frac{1}{2}$ of the length of the head, and equals the extent of the fin itself; the fourth spine slightly exceeds $\frac{1}{2}$ of the length of the preceding three. At the base appears an elongated scale, extending to the posterior margin of the fin. The second dorsal spine is situated in the centre between the muzzle and the root of the caudal fin. The posterior dorsal fin is situated at equal distance from the anterior and from the root of the caudal, and it commences opposite the anterior anal ray. The upper margin is falcated; the eighth ray is a little longer than the preceding. The extent of the fin equals that of the anterior dorsal. The posterior margin of the caudal is lunated. The anal fin is nearly triangular, but that the posterior ray slightly exceeds the preceding; the third spine is $\frac{1}{3}$ the length of the anterior ray. The length of the pointed, slightly falcated, pectoral fin is $\frac{1}{5}$ less than the length of the head; above the superior margin appears an elongated, knife-blade-like scale, $\frac{1}{2}$ the length of the fin. The ventral fins commence opposite the posterior half of the pectorals; their length equals $\frac{1}{2}$ of

that of the head. The elongated scale above the root extends to the margin of the membrane which connects the anterior half of the fifth ray to the abdomen. The elongated scale between the fins is broader and projects far behind the latter connecting membrane. A single young individual was obtained from a part of the Pinang River, (Sungei Pinang), where the water is fresh.

Sub Fam. ATHERINOINÆ.

Genus ATHERINA, (*Artedi*), *Linne*, 1766. Body elongated; two widely separated dorsals; ventrals behind the pectorals; upper jaw protractile; minute teeth in both jaws; in some species also on the vomer, palatals and pterygoids; each side with a broad silvery band. Branchiostegous rays six.

(3701) *Atherian forskali*, Ruppell.

Syn. Atherina hepsetus, Forskal 69, No. 101?
Atherina forskalii. Ruppell: Neue Wirbelth, Fische: 132. Tab. 33, Fig. 1.

Head above, back and upper third of the sides pale sea green, dotted with black; from the axilla to the caudal a light blue longitudinal line, under which a pale yellowish, bordered beneath by a broad shining silvery band; muzzle and lips blackish; cheeks and opercles shining silvery, upper half of the latter steel-blue; throat and abdomen silvery white; fins hyaline, margins of spines and rays of the dorsals, caudal and pectorals minutely dotted with black; posterior margin of caudal blackish. Iris silvery; above the pupil a transverse bluish black spot. D 5—1/9 or 10, C 17 $\frac{2}{3}$, A 1/13, V 1/5, P 15, Br. VI. Inhabits *Sea of Pinang*, Red Sea. Total length: 3 $\frac{2}{8}$ inch. The length of the head is 3 $\frac{4}{5}$ in the total, measured to the centre of the posterior margin of the caudal. On each side of the flattened vertex, where the opercle joins, appears a longitudinal furrow containing two or three pores. Three or four such appear on the infraorbitals, several beneath the nostrils, and three beneath each branch of the lower jaw. The diameter of the eye is 2 $\frac{1}{2}$ in the length of the head. At the lower part of the ascending margin of the preopercle, near the angle, is a deep incision. In both jaws, on the vomer, palatals and pterygoids appear bands of velvety teeth. The vertical diameter at the ventrals is 5 $\frac{1}{3}$ in the total length. The anterior dorsal fin commences a little behind the centre of the back; the four first rays are placed close together; the fifth is somewhat removed from the fourth. The body is covered with seven longitudinal series of rather large scales; the third series from above carries the lateral line, which consists of a minute notch on the posterior margin of each scale. The anterior 7 or 8 scales of the series appear to have no such notch, so that the lateral line appears to commence on the ninth scale. The pectorals are triangular, a little downwards pointed; their length slightly exceeds $\frac{1}{6}$ of the total length. The last ray of the second dorsal, and of the anal fin is a little elongated. Two individuals observed at Pinang in July 1843 and April 1845, differ from Dr. Ruppell's description in having five instead of six spines in the anterior dorsal fin. The smaller, 2 $\frac{4}{5}$ inches in length, is of a more elongated form, its vertical diameter at the ventrals being $\frac{1}{6}$ of the total length. It is also distinguished by having on the vertex a small raised triangular space, resembling an escutcheon, with the point between the orbits. The latter ('ecusson'), is described by M.M. Cuvier and Valenciennes as a character distinguishing *Atherina lacunosa*, Forster. As both individuals examined at Pinang present similar pores, and the characteristic incision of the margin of the preopercle, neither of which characters are noted in the description of *A. lacunosa*, their identity with *A. forskali* cannot be doubted.

Fam. SCOMBROIDÆ.

Genus SCOMBER (*Artedi*) *Linne*, 1748. Anterior dorsal fin separated by a considerable interval from the second, the posterior part of which as well as of the anal fin, forms five spurious fins; on each side of the tail two small crests, the one above the other; body fusiform with small smooth scales. Branchiostegous rays 7.

(3702) *Scomber Microlepidotus*, Ruppell.

Syn. Scomber microlepidotus, Ruppell: Neue Wirbelth. Fische p. 38, Taf 11.Fig.2.

Head above, back and sides as far as the lateral line intense steel-blue, after death with three irregular series of black spots; sides of the occiput and of the body immediately beneath the lateral line silvery light blue; lower part of the sides, abdomen, and sides of the head shining silvery, immediately behind the angle of the mouth a black triangular spot; membrane of anterior dorsal transparent, scantily dotted with brown along the spines; second dorsal, caudal, anal and the spurious fins pale yellow; the dorsal spurious fins and the caudal with black margins; ventrals and pectorals whitish, the latter with a blackish line along the root. Iris silvery round the pupil, the rest bluish black. D 9—12—V, C 17 $\frac{2}{3}$, A 1/11—V, V 1/5, P 18, Br, VII. Inhabits *Sea of Pinang*, Massaua, (Red Sea.) Total length: 5 inch. The length of the head is 3 $\frac{1}{2}$ in the total. The diameter of the orbit is 3 $\frac{1}{2}$ in the length of the head; the distance between the eyes across the forehead is $\frac{2}{3}$ of the diameter. The anterior and posterior thirds of the eye are covered by an adipose crescent-shaped membrane, leaving a central, lanceolate space open. A single series of minute, yet visible teeth, appear in both jaws. The cavity of the mouth is whitish, minutely dotted with black; the anterior part of the tongue is flattened, round-

ed, and closely dotted with black, the posterior part is a narrow linear crest, covered by a series of small rounded spots of velvety teeth. The sides of the head are scaleless, except the cheeks, or the anterior half of the preopercle, which as well as the space below the pectoral fins are covered with scales, larger than the very small ones of the body. Along the lower margin of the preopercle, appear some rather indistinct radiating lines. The vertical diameter in front of the anterior dorsal is $4\frac{1}{2}$ in the total length. The first spine of the anterior dorsal fin is but little shorter than the second, (in the figure of Russell No. CXXXVI, *Scomber kanagurta*, Cuv. its length is $\frac{1}{3}$ of the second,) the second and third are each $2\frac{1}{2}$ in the length of the head. Although the present fish differs from Dr. Ruppell's in having 9 instead of 10 spines in the anterior dorsal fin, in other characters both agree so perfectly that they appear to be identical. A single individual was observed in August 1844, at Pinang.

Genus THYNNUS (*Willoughby*, 1686), *Cuvier*, 1817. Round the thorax a kind of corslet formed by scales larger, but less smooth than those of the rest of the body; a cartilaginous keel on each side of the tail between two small crests; anterior dorsal fin elongated, separated by a very short interval from the second.

(3703) *Thynnus affinis*, Cantor. Head above and back indigo-blue, lighter, silvery, with rose-colored reflections on the sides above the lateral line; from the angle between the points of the corslet to the tail, a number of oblique, backwards and upwards directed undulating blackish bands; sides beneath the lateral line and abdomen pale silvery or satin, with rose-coloured and light-blue reflections; cheeks and opercles shining silvery with similar reflections; anterior dorsal fin greyish buff with a dark brown line along the anterior margin of the six first spines, changing to a triangular spot in front of the succeeding ones; second dorsal, anal and their spurious fins pale brownish yellow, edged and washed with blackish; caudal yellowish buff, washed with brownish in the centre; ventrals brownish grey; pectorals silvery grey, blackish towards the margin. Iris silvery, blackish blue towards the orbit. D 15—3/10—VIII, C $17\frac{6}{9}$, A 3/11—VII, V 1/5 P 27, Br. VII. Inhabits *Sea of Penang*. Total length: 1 foot 10 inch. In general outline this species resembles *T. pelamys* (Linne). But compared with the description and figure of the latter species, (Cuv. and Val. T. VIII. p. 113, Pl. 214,) the present differs in colours, number of fin rays and in characters to be pointed out. The length of the head is contained three times in the distance from the symphysis of the lower jaw to the centre of a vertical line drawn between the fifth dorsal and the anal spurious fins; it is about $3\frac{1}{3}$ in the total length. (In *T. pelamys* the head but slightly exceeds $\frac{1}{3}$ of the latter.) The height at occiput is $\frac{3}{4}$ of the length of the head. The vertical diameter of the eyes is $\frac{1}{5}$, the horizontal $\frac{1}{7}$ of the distance from the point of the upper jaw to the gill-opening. (In *pelamys* the diameter of the eye is $5\frac{1}{2}$ in the distance given.) In the upper jaw appear 23 distant, small, inwards arched teeth; in the lower 30, the posterior of which are a little stronger than the rest. The posterior part of the external margin of the palatal bones carries a single series of very minute teeth. The tongue is free, flattened, oval, and as well as the whole cavity, of a pale blackish blue colour. The vertical diameter in front of the pectoral fins is $4\frac{1}{4}$ in the total length. The anterior dorsal spine is placed opposite the second seventh of the pectoral fin. Its length is $\frac{1}{2}$ of the head, taken from the symphysis of the lower jaw. (In *pelamys* it is shorter.) The second spine is nearly as long, but only half the breadth of the preceding; the rest gradually decrease in length to the sixth, which is about $\frac{1}{3}$ longer than the seventh; the succeeding decrease less perceptibly towards the fifteenth, the length of which is about $\frac{1}{2}$ of the seventh. The distance between the anterior and second dorsal fin equals the length of the seventh spine. The anterior spine of the second dorsal fin is very short; the third scarcely exceeds $\frac{1}{2}$ of the first ray: all three spines are so completely hid by the integuments, as to be nearly imperceptible unless the latter be removed, and such is also the case with the spines of the anal fin. A vertical line drawn between the points of the caudal fin is contained a little more than $3\frac{1}{2}$ (in *pelamys* scarcely more than 3) times in the total length. The length of the pectorals fin is $6\frac{1}{2}$ in the total length. The ventrals are $\frac{2}{3}$ of the length of the pectorals, and each is received into a furrow, externally bounded by a fold of the corslet. Between the fins appears an elongated lamina, in length equalling the fifth ray, the anterior half of which is connected by a membrane to the abdomen. The corslet consists of three points: the superior extends to and clasps the second dorsal fin. The series of scales nearest the anterior dorsal fin, particularly those of the anterior part, are very large, nearly rhombic; the next three series are smaller, yet conspicuously larger than the rest. The central point, the largest, commences opposite the seventh dorsal spine, and terminates in a blunt point opposite the fourteenth spine, while the lower, somewhat undulating margin, extends to a little in front of the origin of the ventral fins. Between the occiput and the anterior third of the pectoral fin, appears an oblique triangular space, covered with narrow elongated scales, but bounded behind by 4 or 5 oblique series of large rectangular scales. The lateral line commences gently ascending towards the sixth dorsal spine, from whence it gently descends till opposite the anterior dorsal spurious fin, when it proceeds straight to the

cartilaginous keel of the tail. The third point of the corslet terminates on the abdomen, opposite the point of the pectoral fins. A single individual occurred at Pinang in December 1844.

Genus CYBIUM, *Cuvier*, 1829. Body elongated, without corslet; maxillary teeth large, compressed, trenchant, (lancet-shaped;) palatal bones, anterior part of vomer, tongue and branchial arches with velvety teeth.

(3704) *Cybium commersoni*, (Lacepede.)

Syn. Scomber commerson, Lacep. II. 600, Tab. 20, Fig. 1.
Scomber maculosus, Shaw: Nat. Misc. No 982.
Russell, CXXXV. Konam.
Scomber commersonii, Shaw: Gen. Zool. IV., 589, Pl. 85.
Scomber maculosus, *Ibid.* p. 592.

Cybium commersonii, Ruppel: Neue Wirbelth, Fische, p. 41.
Cybium commersonii? Richardson: Report, 1845, 268.
Ikan Tanggiri of the Malays.

Head above and back intense blue with golden green reflections, lighter on the sides of the head and body to a little beneath the lateral line; the rest of the sides, the abdomen, opercles and cheeks shining silvery with lilac reflections; membrane of the anterior dorsal fin pale lilac grey, minutely dotted with brown, upper margin black; second dorsal, anal and their spurious fins pale silvery lilac grey; anal and its spurious fins with white margins; caudal silvery blackish; ventrals white; anterior half of pectorals white, posterior blackish; between the gill-opening and the root of the upper margin of the pectorals a large black spot. Iris silvery, bluish black near the orbit. After death the sides above the lateral line acquire a number of close, vertical undulating lines and spots; beneath the lateral line appear fewer and more distant black lines. D 17—4/13—X, C 17$\frac{1}{1}$, A 4/13—X, V 1/5, P 23, Br. VII. [The anterior dorsal and the anal fin rays are preceded by four spines (undivided rays) which however cannot distinctly be perceived without removing the covering scales and integuments. The caudal fin consists of 17 central branched rays, above and below which appear 14 gradually decreasing, undivided rays. The following number of fin-rays have been given by the different describers: Russell, whose figure is more correct than his description: D 16—16, C 24, A 14, V 6, P 22, Br. VII. Ruppell: D 16—14—X, C 26, A 3/14—X, V 1/5, P 24, Br. VI. Cuvier and Valenciennes: D 16—1/15—X, A 1/15—IX, P 22 or 23, Br. VII.] Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Isle of France, Coromandel, Bay of Bengal, Massaua, (Red Sea,) China Seas. Total length: 3 feet. The length of the head is 4$\frac{1}{3}$ in the total. The orbit is surrounded by a circular, rather broad, adipose membrane. The diameter of the orbit is a little less than $\frac{1}{4}$ of the length of the head; the distance of the eyes across the forehead is a little less than two diameters. In the upper jaw appear on each side 20 to 25 large lancet-shaped teeth in the lower 10 to 15, of which the posterior ones are the largest of all; velvety teeth appear on the anterior part of vomer, on the palatals, pterygoids, on the tongue, and on the margin as well as the internal surface of each hyoid bone. The only perceptible, small elongated scales appear along the anterior dorsal, on the second dorsal, caudal and anal fins, and from behind the infraorbitals round the eye to the occiput. The vertical diameter in front of the anterior dorsal is $\frac{1}{7}$ of the total length. The lateral line deviates but little from the upper third of the body, till opposite the first spurious dorsal fin, when it suddenly descends, describing an arch which terminates nearly opposite the fourth spurious dorsal fin; from thence it proceeds in the middle of the body, over the strong keel in front of the caudal fin. Both in front of and behind the arch, the lateral line makes a few, in different individuals varying, slight undulations. The spines of the anterior dorsal fin terminate in excessively slender points, which when uninjured are completely connected by the membrane. Such, indeed, was the case but in very few young individuals observed at Pinang, the instant they were taken out of the sea. The membrane, however, is easily torn and the spines are left each terminating in a filament as represented by Dr. Ruppell (Atlas: Taf. 25, fig. 1). The fish occurs at Pinang during all seasons, but not in numbers. As an article of food it is there valued both in its fresh and dried state. Single individuals may be seen in the cold season, but very rarely, in the Calcutta bazars. But they are not eaten by Europeans, as this as well as other Indian mackarels requires to be very fresh, to be fit for the table.

(3705) *Cybium lineolatum*, Cuvier.

Syn. Cybium lineolatum, Cuv. and Val. VIII. 170.
Cybium lineolatum, Belanger: Voyage, p. 366, Pl. II. Fig. 1.
Cybium lineolatum, Bleeker: Verh. Bat. Gen. XXII. 4.
Tanggiri of the Malays.

Head above and back intense blue with golden green reflections, lighter on the sides of the head and body, to a little beneath the anterior half of the lateral line; the rest of the sides, the abdomen, opercles and cheeks shining silvery with pale lilac reflections; membrane of anterior dorsal fin pale lilac grey, minutely dotted with brown, upper margin black; second dorsal and

purious fins pale silvery lilac grey; caudal silvery blackish grey: anal and spurious fins silvery white; ventrals white; pectorals silvery white, minutely dotted with black on the posterior outer half and on the whole inner surface, so closely as to appear blackish. Iris silvery, bluish black towards the orbit. After death appear several series of black spots: irregular above the lateral line; beneath the latter three or four series of longitudinal short linear spots, each series appearing like an interrupted line. D 16—4/12—IX, C 15$\frac{1}{1}$, A 5/14—X, V 1/5, P 21, Br. VII. Inhabits *Sea of Pinang, Peninsula, Singapore,* Malabar, Bay of Bengal, Madura, Java. Total length: 2 feet. The length of the head is 4$\frac{1}{2}$ in the total measured to the centre of the posterior caudal margin, but $\frac{1}{5}$ to the centre of a vertical line between the points of the caudal lobes. The diameter of the orbit is 4$\frac{1}{2}$ in the length of the head; the margin of the orbit supports a rather broad circular adipose membrane. The distance of the eyes across the forehead is 1$\frac{1}{4}$ diameter. On each side of both jaws appear upwards of 18 lancet-shaped large teeth, of which, however, more than 10 or 11 are seldom present. The middle ones of the lower jaw are the largest. On the anterior part of the vomer appears a pointed triangular spot with velvety teeth, and on each palatal and pterygoid a rather broad continued line of similar teeth. Others appear at the root of the small oval, flattened tongue, on the margin and internal surface of each hyoid bone. The scales are perceptible in the places noted under *Cybium commersoni.* The greatest vertical diameter slightly exceeds $\frac{1}{6}$ of the total length. The lateral line, a series of short rectangular elevations, commences following the upper fourth of the body, from which it gently deviates towards the termination of the second dorsal fin; from thence it continues declining to below the middle of the body, opposite the fifth spurious fin, when it slightly ascends towards the strong keel in front of the caudal fin. The spines of the anterior dorsal fin are very slender, and the membrane is easily detached, so as to leave the filamentous points of the anterior and the whole of the posterior five or six very short spines unconnected. The anterior spine scarcely equalling the diameter of the eye, is $\frac{2}{3}$ of the length of the second, which is shorter than the third. The fourth, the longest, is $\frac{1}{4}$ of the length of the head; the rest gradually decrease; the sixteenth is so short and slender that it easily may escape observation. The anterior spurious fin is often by a short membrane connected to the second dorsal and anal. Each caudal lobe equals the length of the head. The length of the pectorals is 8$\frac{1}{2}$ in the total; the ventrals $\frac{1}{3}$ of the pectorals. At Pinang this species occurs at all seasons, but not in numbers. In quality it resembles *C. commersoni,* and like it, a solitary, stray one, may, during the cold season, be seen in the fish bazars of Calcutta.

(3706) *Cybium guttatum.* (Bloch-Schneider).

Syn. Scomber guttatus, Bl.-Schn. 23, Pl. 5.
Russell, CXXXIV. Wingeram.
Scomber leopardus, Shaw? Gen. Zool. IV. 591.
Cybium guttatum, Cuv. R.A. II. 200 (1).
Cybium guttatum, Cuv. and Val. VIII. 173.
Cybium kuhlii, Cuv. and Val. *Ibid.* 178 (*Young*).
Cybium guttatum Richardson Report, 1845. 268.
Cybium guttatum, Bleeker: Verh: Bat. Gen. XXII. 4.
Tanggiri papan of the Malays.

Adult. Membrane of the first seven or nine spines of anterior dorsal fin black, that of the succeeding spines white, minutely dotted with brown, and broadly edged with black; rest of the body and eyes coloured like *Cybium lineolatum.* After death appear on the back and upper half of the sides numerous black rounded and oval spots, of different sizes, mostly irregularly scattered, here and there in regular longitudinal series. D 18—4/16—X, C 15$\frac{10}{10}$, A 5/16—IX, V 1/5, P 21, Br. VII. or D 17—5/16—X, A 6/16—IX. *Young.* Ventrals, second dorsal, anal and their spurious fins pale yellowish; caudal whitish, the root the posterior margin and between the central five rays silvery bluish. Rest of the body like the adult, but no black spots appear after death. D 17—5/17—VII, A 6/16—VII, or D 15—5/16—VIII, A 6/16—VIII. Inhabits *Sea of Pinang, Malayan Peninsula Singapore,* Java, Madura, Malabar, Coromandel. Total length: 3 feet. The length of the head is $\frac{1}{5}$ of the total, measured to the centre of the posterior caudal margin, but 5$\frac{1}{2}$ in the total centre of a vertical line between the points of the caudal lobes. The orbit is surrounded by a circular adipose membrane. The diameter of the orbit is $\frac{1}{4}$ of the length of the head. The distance of the eyes across the forehead is 1$\frac{1}{2}$ diameter. The maxillary teeth are generally shorter and less broad than in *C. commersoni* or *lineolatum.* On each side of the upper jaw appear upwards of 19, of the lower upwards of 15 teeth. The velvety teeth are disposed as in *C. lineolatum,* but they are more numerous, as the whole of the roof of the mouth, bounded in front by the vomer and on each side by the palatals, is studded with patches of teeth. The very centre of the roof behind the anterior pointed part of vomer, presents a singular appearance: it is covered with linear elevations separated from each other by narrower lines of the naked lining membrane. The greatest vertical diameter in front of the second dorsal fin equals the length of the head. The lateral line, consisting of little rectangular elevations follows the outline of the back while gently de-

clining till opposite the third or fourth dorsal spurious fin; from thence it continues straight to the strong keel in front of the caudal fin. In the young of this and the preceding species the latter keel is very little developed. Single individuals occur at Pinang at all seasons, and are valued as articles of food. In Calcutta they are very rarely seen, and during the cold season only.

Genus TRICHIURUS, *Linne*, 1766. Body elongated, compressed, with a single extensive dorsal fin; tail terminating in a slender finless filament; neither ventrals nor anal, but instead of the latter a number of minute spines; muzzle elongated; lower jaw projecting beyond the upper, both with distant lancet-shaped teeth, among which several arched ones longer than the rest, and with the posterior part of the point barbed; each palatal with a series of velvety teeth. Branchiostegous rays seven.

(3707) *Trichiurus haumela*, (Forskal,)

Trichiurus haumela, Ruppell, N, W. Fische, 41.
Trichiurus haumela, Swainson, II. 254.
Trichiurus haumela, Bleeker: Verh. Batav. Gen. XXII. 4.
Ikan Puchuk of the Malays.

Adult. Head above, back and naked point of the tail blue blackish, lighter silvery on the jaws sides of the head and body; abdomen silvery; dorsal rays and membrane pale reddish yellow, the latter to the twelfth ray, and from thence the upper half, minutely dotted with black, so as to appear blackish; anterior third of pectorals pale reddish yellow, the rest blackish. Iris silvery blue, blackish towards the orbit. *Young.* Head above, back and naked point of the tail silvery bluish: the rest of the body shining silvery; dorsal and pectorals yellowish white, minutely dotted with black like the adult, without, however, acquiring the blackish general appearance of the latter. D 127 to 133, P 11, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore,* Chusan, Canton River, Coromandel, Bay of Bengal, Gangetic estuaries, Malabar, Djetta, (Red Sea,) Java, Celebes, Madura. Total length: 2 feet 8 inch. The length of the head, measured from the symphysis of the lower jaw to the termination of the opercle, is $\frac{1}{4}$ of the total. The diameter of the eye is $\frac{1}{6}$ of the length of the head, or $\frac{1}{2}$ of the vertical diameter of head, through the eye itself. In the upper jaw appear on each side upwards of 15 distant teeth, of which the anterior pair which are present in the very young ones only, are directed forwards. Behind these appear a pair, or a single lower arched tooth, the posterior part of the point of which is barbed. Next follow 3 or 4 very small lancet-shaped, behind which is a very long arched, half-barbed tooth. The rest of the space is occupied by some distant lancet-shaped teeth, of which those in the middle are the largest. On each side of the symphysis of the lower jaw appears an arched tooth, like the corresponding one of the upper jaw, but shorter. Behind the tooth is a vacant space, followed by upwards of 12 lancet-shaped teeth, which with the exception of one or two half-barbed in the middle, are smaller than the corresponding of the upper jaw. Along the margin of each palatal is a series of velvety teeth. The tongue is small, oval, a little pointed, and smooth. The anterior dorsal ray is $\frac{1}{4}$ of the length of the head. The greatest vertical diameter of the body is generally $\frac{1}{15}$, but in the adult $\frac{1}{17}$ of the total length. This species is excessively numerous at all seasons in the Straits of Malacca and in the estuaries of the Ganges. The common length is about one foot, and but a solitary individual of 2 feet 8 inch was observed at Pinang. The fish is consumed fresh, but chiefly dried, by the natives, and forms in the latter state an article of exportation. It is of voracious habits, devouring its own kind, as well as other fishes, and crustacea. The adult had a nodulous enlargement of the size of a coffee seed, on one of the anal interspinal bones, similar to those observed in *Platax arthriticus*, Cuv. and Val.

(3708) *Trichiurus savala*, Cuvier.

Syn. Trichiurus savala, Cuvier, R. A. II. p. 219.
Trichiurus armatus, Gray: Zool. Misc. 9. (*Excl. Syn. Sawala, Russell.*)
(*Icon.*) Trichiurus armatus, Gray: Ill. Ind. Zool. II. Pl. 93, Fig. 1.

Trichiurus savala, Cantor: Ann. Nat. Hist. IX. 15.
Trichiurus armatus, Richardson, Report, 1845, 268.
Puchuk of the Malays.

Head above, back and the naked point of the tail pale bluish, all other parts shining silvery; dorsal and pectoral rays yellowish white, their membrane hyaline. Iris silvery, bluish towards the orbit. D 112 to 120, P 11, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore,* Canton River, Chusan, Pondicherry, Bay of Bengal, Gangetic estuaries, Malabar, China Seas. Total length; 1 foot 4 inch. The length of the head is from $6\frac{1}{2}$ to $7\frac{1}{4}$ in the total. The diameter of the eye is from $8\frac{1}{2}$ to $\frac{1}{5}$ of the length of the head, or $\frac{3}{4}$ of the vertical diameter

of the head through the eye itself. The anterior rays of the dorsal fin are proportionally shorter than in *T. haumela:* the length of the first ray but slightly exceeds the diameter of the eye. The lancet-shaped teeth of the jaws are proportionally smaller than in the preceding species, which it in other respects greatly resembles. Although not very scarce at Pinang and at the Sandheads, it is of far rarer occurrence than *T. haumela*, which it resembles in voracious habits. As observed by M.M. Cuvier and Valenciennes, neither species is electrical, but both give at certain seasons, like many other fishes, a vivid phosphoric light.

Genus ELACATE, *Cuvier*, 1829. Head depressed; body fusiform; a number of free spines preceding the dorsal fin, but none the anal; no keel in front of the caudal fin.

(3709) *Elacate bivittata*, Cuv. and Val.

Syn. Elacate bivittata, Cuv. and Val. VIII. 338.
Elacate bivittata, Temm. Schl. Fauna Japon. Pisc. 104. Pl. LVI
Elacate bivittata, Richardson, Report, 1845, 269.

Head above and back inky, or bluish black; from the posterior part of the orbit to the root of caudal, a pale silvery longitudinal band, dotted with black; from the shoulder, enclosing the posterior $\frac{1}{4}$ of the lateral line, an intense bluish black band; beneath which a narrower, pale silvery, dotted with black; under which a bluish black; throat and abdomen pale silvery, dotted with black; upper half of sides of the head silvery blackish; lower half: pale silvery dotted with black; dorsal free spines, and all fin rays whitish; their membranes pale greyish, minutely dotted brown so as to acquire a general brownish, or bluish black appearance; caudal whitish at the root, and with a white triangular spot at the upper and lower angle; in some the posterior margin whitish; pectorals whitish at the root, the rest intense black. Iris silvery, minutely dotted with black. D 8—2/30, 34, 35 or 36, C $17\frac{1}{1}\frac{3}{3}$, A 2/25, 26, 27 or 28, V 1/5, P 20, Br. VII. Inhabits *Sea of Pinang, Singapore*, Moluccas, Japan, China Seas. Total length: 2 feet. The length of the head is $\frac{1}{5}$ of the total. The eye is surrounded by a large circular adipose membrane. The transversal diameter of the orbit is $\frac{1}{4}$, the vertical $\frac{1}{5}$ of the length of the head. The distance of the orbits across the forehead slightly exceeds their transversal diameter. The diameter of the eye itself is $\frac{1}{6}$ of the length of the head. Besides the cardlike teeth of both jaws, the vomer and the palatals, the whole of the roof of the mouth between the three latter bones, the tongue and the innerside of the gums are covered with velvety teeth. As in *E. pondiceriana*, Cuv. and Val. the upper surface of the cranium has on each side a fascicle of striæ, radiating forwards and backwards. They are indeed less apparent during life and in specimens preserved in spirits, than in dried ones, which probably accounts for M.M. Cuvier and Valenciennes describing the surface as nearly smooth (VIII. p. 338). On each opercle appear upwards of 9 backwards radiating, sharp striæ. Each side of the occiput and the cheeks are covered with small oval, slightly pointed scales, like those of the body; the rest of the head is naked. The eight free dorsal spines are all directed backwards; each is attached to its groove by a small triangular membrane. The anterior ray of the dorsal and anal fins is shorter than the second, and not branched like all the succeeding. The lateral line proceeds nearly straight towards the termination of the pectorals from whence it gently declines, keeping the middle of the body, and terminating a little in front of the posterior margin of the caudal. It makes several slight undulations, and the anterior portion is sometimes found double, the one above the other. The length of the caudal fin is $\frac{1}{5}$ of the total; the posterior margin is straight, vertical. The pectoral is a little falcated; the length $\frac{1}{7}$ of the total, nearly double the length of the ventrals. The stomach is an elongated muscular sac; at some distance from the pylorus appears a cœcum nearly as long as the stomach, from the side of which proceed a number of short processes, each terminating in many minute branches, all forming a countless mass of cœca. The intestinal canal makes a single circumvolution: its length is about $\frac{1}{3}$ of the total. The liver is elongated, single-lobed. The gall-bladder is reduced to a narrow tube. The spleen is small triangular. There is no air-vessel. In several dissected the stomach contained fishes (*Clupeoidæ*) and *Loligo*. Single individuals occur at all seasons at Pinang. They are eaten by the natives.

Genus CHORINEMUS, *Cuv. and Val.* 1831. [Substituted for *Scomberoides*, Lacepede, 1800.] Body oblong, compressed; no keel in front of the caudal fin; anterior dorsal fin consisting of singly moveable spines, each with a small membrane; the first of these spines preceded by an immoveable one, [as the immoveable spine is rarely perceptible except in very young individuals, it will not be given in the formulas of the dorsal fins, but special mention will be made of it,] more or less hid in the skin and pointing forwards; rays of the second dorsal and anal fin either entirely detached, or united by a membrane so brittle, as to easily disappear, and make the rays resemble spurious fins; two free spines, resembling those of the anterior dorsal, behind the anus.

(3710) *Chorinemus lysan*, (Forskal).

Chorinemus lyzan, Cuv. and Val. VIII. 387.
Chorinemus lysan, Ruppell, N. W. Fische 44.
Chorinemus commersonii, Bleeker: Verh. Batav. Gen. XXII. 4.
Tallang raya of the Malays.

Head above and back golden greenish olive, the rest of the head and body brilliant golden citrine or sulphur colour; second dorsal, anal, pectoral and caudal like the body, but not golden; posterior margin of caudal blackish, anterior dorsal, ventrals and post-anal spines white. Iris golden sulphur-coloured, greenish towards the orbit. *After death.* Head above and back greyish olive, lighter on the sides towards the lateral line; rest of the head and body silvery; sides along or above the lateral line with 6 or 7 large oval blue-blackish or greyish spots; second dorsal, anal, pectoral and caudal yellowish white. Iris silvery. D 7 or 6—1/20, C 17/7, A 2—1/18, V 1/5, P 18, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore,* Sumatra, Java, Madura, Coromandel, Red Sea, Madagascar. Total length: 2 feet. The length of the head is 4⅔ in the total, measured to the centre of the posterior margin of the caudal; the height at occiput nearly equals the length of the head. The diameter of the orbit, supporting an adipose membrane, is ¼ of the length of the head; the distance across the forehead equals the diameter. The angle of the mouth is situated at some distance behind the orbit; the distance from the muzzle to the angle of the mouth slightly exceeds ½ the length of the head. The immoveable spine preceding the first dorsal, is apparent in the very young, but later it becomes entirely hid by the integuments. The lateral line forms an obtuse angle opposite the first dorsal spine, and at equal distance between the latter and the middle of the pectoral fin. The anterior of the black spots which appear after death is situated beneath the origin of the lateral line, between it and the root of the pectoral; the upper part of the opercle becomes frequently blackish; of the rest of the spots, the two or three are above, but touch the lateral line; the others are altogether above it. The scales are minute, oval, with a longitudinal central furrow, and enveloped in the transparent epidermis. The greatest vertical diameter of the body, in front of the posterior dorsal fin varies from 3¼ to 3½ in the total length. At Pinang single individuals occur at all seasons. They are eaten either fresh or dried by the natives.

(3711) *Chorinemus tol.*, Cuvier and Valenciennes.

Syn. Russell, CXXXVIII. Tol Parah.
Chorinemus tol, Cuv. and Val. VIII p. 385.

Head above the back metallic bluish grey, lighter on the sides to a little above the lateral line; opercles and the rest of the body silvery white; pectorals and caudal yellowish white, the latter edged with blackish; the rest of the fins white; the angle of the second dorsal fin black. Iris silvery, bluish black towards the orbit. *After death.* Upper part of opercle and a spot immediately behind it, metallic bluish grey; in some a series of from 6 to 8 similar spots above the lateral line. D 7—1/20 or 21, C 17/6, A 2—1/18, 19 or 20, V 1/5, P 18, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore,* Amboyna, Buru, Coromandel, Bay of Bengal, mouths of the Ganges, Malabar. Total length: 8⅝ inch. The length of the head is from 4¾ to ⅕ of the total, measured to the centre of the posterior margin of the caudal fin; the depth at occiput is ¾ of the length of the head. The transversal diameter of the orbit is 3½ of the length of the head; the distance across the forehead equals the diameter. The greatest vertical diameter of the body equals the length of the head. The lateral line makes a very obtuse angle opposite the third dorsal spine, from thence it declines till opposite the third or fourth ray of the second dorsal, when it proceeds straight to the centre of the caudal. The length of the lobes of the caudal equals that of the head, but generally one of the lobes is shorter than the other. The length of the pectorals and ventrals slightly exceeds ⅓ of the length of the head. The angle of the mouth is situated beneath the centre of the orbit; the lower jaw slightly projects beyond the upper. The scales appear like numerous, close, horizontal needles. The immoveable spine preceding the first dorsal, is in some partially apparent, in others entirely hidden. Younger individuals are at Pinang excessively numerous during all seasons, and are dried by the natives.

Genus TRACHYNOTUS, (*Lacep*) *Cuvier*, 1817. (Cæsiomorus, *Lacep.* 1800.—Acanthinion, *Lacep.* 1802.—) Differs from Gen. *Lichia* by a more elevated body, a profile more rapidly descending in front of the eyes, and by the more elongated points of the second dorsal and anal fin.

(3712) *Trachynotus mookalee*, Cuv. and Val.

Syn. Gasterosteus ovatus, Linne, Syst: 1325?
Centronote ovale, Lacepede?
Russell, CLIV. Mookalee Parah. Dr. Ruppell consider this identical with *Trachynotus falcatus*, (Forsk.) of which also the following synonymes are given: *Scomber falcatus*, Forskal, p. 57, No. 76.—*Cæsiomorus blochii*, Lacep. III. Tab. 3, Fig. 2,—(Ruppell: Atlas, p.

88.) To these Dr. Cantor has later added: *Trachinotus drepanis*, Cuv. and Val. VIII. 429, Trachinotus mookalee, Cuv. and Val. VIII. 423

Head above and back silvery green; sides above the lateral line golden green; beneath the line, abdomen and opercles golden gamboge; all fins gamboge; anterior margin of dorsal spines and first ray of second dorsal blackish; membrane of second dorsal, caudal and pectorals minutely dotted with brown. Iris golden gamboge, Green towards the orbit. D 6 —1/19. C $17\frac{2}{3}$, A 2—1/17, V 1/5, P 20, Br. VII. Inhabits *Sea of Pinang*, Coromandel, Malabar. Total length: 8 inch. The length of the head is $\frac{1}{4}$ of the total measured to the centre of the posterior margin of the caudal; the depth at the occiput exceeds by $\frac{1}{8}$ the length of the head. The diameter of the orbit is $\frac{1}{4}$ of the length of the head. The infraorbital is broad, rounded in front, tapering to a point beneath the centre of the orbit, so as to leave the inferior half of the narrow maxillary bone exposed. The preopercle consists of a very narrow vertical portion, and a shorter, broader horizontal; where both join, the posterior margin describes a segment of a circle. The external surface is divided in two parts by a ridge in the middle: the anterior part has at the angle four longer and several smaller spine-like radiating processes, between which appear numerous radiating lines which continue along the vertical part of the posterior margin, which has the appearance of being very finely denticulated in an oblique upward direction. The angle of the mouth is situated in front of the orbit. In a young individual, $3\frac{3}{8}$ inches in length, a band of card-like teeth appear in both jaws; but in another, 8 inches in length, the jaws have no perceptible teeth, and such was also the case in those examined by Russell. M.M. Cuvier and Valenciennes describe their specimens of *T. mookalee* with velvety, easily perceptible teeth in both jaws *T. blochii* (Lacep.) and *T. falcatus*, (Forskal), which Dr. Ruppell considers to be identical with the present species, have no teeth. (Cuv. and Val. VIII.) It would therefore appear that some, not all, individuals with age lose their teeth. As a young individual examined at Pinang has very distinct teeth, it follows that the division adopted by Dr. Ruppell (Atlas, p. 88) of *Trachinotus*, Lacep. containing species supposed to have no teeth, is inadmissible. The anterior opening of the nostrils is much smaller than the posterior. The lateral line commences slightly ascending till above the point of the pectoral fin, from whence it gently descends till opposite the posterior third of the second dorsal, when it proceeds straight to the middle of the caudal fin. The scales of the body are very minute, appearing like points. In the young individual examined at Pinang, the spine preceding the movable dorsal ones, had the point projecting, but in the larger one, although perceptible, it was imbedded in the integuments. In Russell's figure the point projects. The length of the point of the second dorsal slightly exceeds $\frac{2}{3}$ of the extent of the base of the fin. The point of the anal is a little shorter. The greatest vertical diameter, in front of the second dorsal, is by $\frac{1}{6}$ less than half of the total length. The lobe of the caudal is $\frac{1}{3}$ of the total length. The length of the pectorals is $\frac{3}{4}$ of the head; that of the ventrals $\frac{1}{2}$ of the pectorals. The two above mentioned individuals were observed at Pinang in June, 1843, and in February, 1845.

(3713) *Trachynotus quadripunctatus*, (Ruppell.)

Syn. Cæsiomorus quadripunctatus, Ruppell: Atlas, p. 90, Tap. 24. Fig. I.
Trachinotus quadripunctatus, Cuv. and Val. VIII. 434.

Head above and back silvery greyish green, lighter on the sides to a little above the lateral line; rest of the sides, abdomen, opercles and cheeks silvery white; on the lateral line 2 to 5 distant black spots; fins hyaline; point of second dorsal and anal, and lobes of caudal black. Iris silvery, greenish towards the orbit. D 6 —1/22, C $17\frac{2}{3}$, A 2—1/22, V 1/5, P 17, Br. VII. Inhabits. *Sea of Pinang*, Massaua, (Red Sea,) Seychelle Islands. Total length: $7\frac{2}{3}$ inch. The length of the head is $4\frac{1}{2}$ in the total, measured to the centre of the posterior margin of the caudal; the depth at the occiput equals the length of the head. The diameter of the orbit is $3\frac{1}{2}$ in the length of the head. The nostrils, the infraorbital and the preopercle resemble *T. mookalee*. In both jaws, on the vomer and palatals appear card-like teeth. The lateral line is slightly arched downwards till the origin of the second dorsal fin, from whence it proceeds straight in the middle of the body towards the caudal. The scales are minute, scarcely perceptible. In the individual examined at Pinang the point of the immovable spine, preceding the first dorsal, projected far beyond the integuments. On the left lateral line appeared four small black spots: the first opposite the 4th dorsal spine, the second, the largest of all, opposite the root of the second dorsal, the third opposite the middle of, and the fourth opposite the termination of the second dorsal. On the right lateral line, however, the last spot was absent. The individual described by Dr. Ruppell had on each side two such spots, corresponding to the second and third in the present. In those examined by M.M. Cuvier and Valenciennes the number of spots varied from 3 to 5. The greatest vertical diameter of the body in front of the second dorsal is $2\frac{1}{4}$ in the total length, measured to the centre of the posterior margin of the caudal. The length of the point

of the second dorsal equals the extent of the base of the fin ; that of the anal slightly exceeds it. The length of the caudal lobes is $2\frac{1}{3}$ in the total, measured as above observed. The pectorals are $\frac{3}{4}$ of the length of the head ; the ventrals $\frac{2}{3}$ of the pectorals. A single individual was taken at Pinang in June 1835, while unusually strong southerly winds prevailed. The fishermen asserted the species to be of very rare occurrence.

Genus APOLECTUS, *Cuvier and Valenciennes*, 1831. Differs from *Trachinotus* by the ventral fins being fixed under the throat.

(3714) *Apolectus stromateus*, Cuv. and Val.

Syn. Apolectus stromateus, Cuv. and Val. IX. 439.

Head above back and sides to the lateral line silvery brownish olive : cheeks, opercles and abdomen silvery pale neutral tint, everywhere minutely dotted with black ; dorsal and anal pale greenish olive, minutely dotted with black ; edges and the posterior part, containing the 3 or 4 last rays yellowish white ; ventrals blackish ; pectorals yellowish white, minutely dotted with black ; caudal yellowish white posterior half minutely dotted with black. Iris silvery buff, orbital half blackish blue. D 4—1/43, C $17\frac{1}{1}$, A 2—1/37, V 1/5, P 21, Br. VI. Inhabits *Sea of Pinang*, Java, Pondicherry. Total length : $3\frac{5}{8}$ inch. The length of the head is $3\frac{1}{2}$ in the total, measured to the centre of the posterior margin of the caudal fin ; the depth at occiput exceeds by $\frac{1}{4}$ the length. The diameter of the eye is $\frac{1}{3}$ of the length of the head. In each jaw appears a single series of excessively fine teeth. The greatest vertical diameter in front of the second dorsal fin is $1\frac{2}{3}$ in the total length. In front of the first minute dorsal spine appears an immovable forward-pointing one, anterior to which two minute spines may be felt by passing the finger along that part of the back. The length of the point of the second dorsal and anal fins is $2\frac{2}{3}$ in the total. That of the falcated pectorals and caudal lobes is $\frac{1}{3}$ of the total length. The ventrals are $\frac{1}{2}$ of the pectorals ; the rays are very slender. A single individual was observed at Pinang in June, 1844.

Genus CARANX, (*Lacep.* 1800,) *Cuvier*, 1828. Lateral line more or less mailed with scaly plates, each keeled and with a spine ; two dorsal fins ; a horizontal immoveable spine in front of the anterior dorsal ; two free spines in front of the anal ; body, the lateral line excepted, covered with small scales ; crest of cranium trenchant ; last rays of second dorsal often slightly connected ; in some separated in spurious fins.

A.—With several spurious fins behind the second dorsal and anal.

(3715) *Caranx rottleri*, (Bloch.)

Syn. Scomber cordyla, Linne, Syst. 1332 ?
Scomber rottleri. Bloch, Tab. 346.
Russell, CXLIII. Worugoo.
Scomber rottleri, Shaw IV. 598.
Caranx rottleri, (Lacep.) Ruppell : Atlas, 102.
Caranx rottleri, Cuv. R. A. II. 208 (')
Caranx rottleri. Cuv. and Val. IX. 29.
Caranx rottleri, Ruppell, N. W. Fische, 48 52.
Caranx rottleri Richardson, Report, 1845, 273.

Head above and back steel blue or silvery dark green, light on the sides towards the lateral line ; the latter as well as the rest of the body shining silvery ; on the upper part of opercle a bluish black spot ; fins transparent, yellowish ; point of the second dorsal, and margin of the caudal minutely dotted with black. Iris silvery ; adipose fold of the orbit pale amber-coloured. D 8—1/30 or 11—IX, C $17\frac{7}{7}$, A 2—1/8—VIII or VII, V 1/5, P 22. Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Coromandel, Malabar, Massaua, (Red Sea,) China Seas. Total length : 7 inch. The length of the head is $\frac{1}{4}$ of the body, the caudal not included : the greatest vertical diameter, in front of the second dorsal fin, is $3\frac{1}{2}$ in the length of the body. The diameter of the orbit is a little less than $\frac{1}{3}$ of the length of the head ; the broad adipose fold of the orbit leaves a vertically oval space, in which the eye appears. The anterior part of the lateral line is formed by very small rounded scales and describes a short high arch, which terminates opposite the middle of the anterior dorsal fin ; the rest of the line is straight, consisting of 53 to 55 oblique, keeled and spinous plates. The anterior of the latter are narrow ; each nearly $\frac{1}{2}$ of the vertical diameter of the body ; the posterior ones increase in breadth and entirely cover the tail. The falcated pectoral fins are $3\frac{1}{2}$ in the total length, measured to the centre of the posterior margin of the caudal. Single individuals occur at all seasons at Pinang. They are eaten by the natives.

B.—Without spurious fins behind the second dorsal and anal fins.

(3716) *Caranx vari*, Cuv. and Val.

Syn. Caranx vari, Cuv. and Val. IX. 48.

Head above and back steel blue with silvery green reflections, lighter on the upper half of the sides ; the rest of the body shining silvery ; abdomen with rose-coloured reflections ; on the upper part of the opercle and at the commencement of the lateral line a large pale bluish-black spot ; anterior dorsal fin black ; second dorsal and caudal pale yellowish white, their marginal halves minutely dotted with black : the rest of the fins hyaline, white ; the middle of the anal sparingly dotted with brown. Iris silvery ; adipose fold of the orbit pale amber-coloured. D 8—1/24, C 17$\frac{4}{4}$, A 2—1/20, V, 1/5, P 19, Br. VII. Inhabits *Sea of Pinang*, Pondicherry. Total length : $6\frac{5}{8}$ inch. The length of the head is $3\frac{1}{2}$ in that of the body, or $3\frac{3}{4}$ in the total measured

to the centre of the posterior margin of the caudal. The inferior margin of the opercle is very slightly concave. The diameter of the orbit is $3\frac{1}{2}$ in the length of the head; the opening of the adipose fold of the orbit is vertically oval. The greatest vertical diameter of the body, in front of the second dorsal, is $\frac{1}{5}$ of the length of the body. The arched portion of the lateral line extends to opposite the anterior part of the second dorsal, the straight portion consists of from 55 to 58 plates, none of which exceeds in height $\frac{1}{9}$ of the greatest vertical diameter of the body. The falcated pectorals are $3\frac{1}{2}$ in the total length. This species is of uncommon occurrence at Pinang.

(3717) *Caranx mate*, Cuv. and Val.

Syn. Caranx mate, Cuv. and Val. IX. 54.

Head above and back steel blue, with silvery green reflections; lighter on the upper half of the sides, rest of the body shining silvery; abdomen with mother-of-pearl reflections; pectoral, caudal and second dorsal yellowish white, the latter minutely dotted with black towards the margin; first dorsal, ventrals and anal whitish, the latter sparingly dotted with brown; upper part of opercle with a bluish black spot. Iris silvery; adipose fold of the orbit pale amber-coloured. D 8—1/24, C $17\frac{1}{2}$. A 2—1/20, V 1/5, P 22, Br. VII. Inhabits *Sea of Pinang*, Seychelles, New Guinea, Anjer, Pondicherry. Total length: $9\frac{1}{8}$ inch. The length of the head slightly exceeds $3\frac{1}{2}$ in the total, measured to the centre of the posterior margin of the caudal; the depth at the occiput is $\frac{3}{4}$ of the length of the head. The diameter of the orbit is $3\frac{2}{3}$ in the latter; the opening of the adipose fold of the orbit is vertically oval. The lower margin of the opercle is nearly straight, or slightly concave about the middle. The greatest vertical diameter of the body in front of the second dorsal is $3\frac{1}{2}$ in the total length. The arched portion of the lateral line terminates opposite the anterior fourth of the second dorsal; the rest is straight and covered by 37 to 40 plates, none of which in height exceeds $\frac{1}{6}$ of the greatest vertical diameter of the body. The length of the falcated pectorals is $3\frac{1}{3}$ in the total. The last dorsal and anal ray is stronger and more elongated than the preceding ones, and as the connecting membrane easily becomes torn, these two rays acquire the appearance of spurious ones. M.M. Cuvier and Valenciennes describe *C. xanthurus* as corresponding in every respect to the present species, except in its having a series of eight or nine dorsal spots of a darker blue than the rest of the back. From *C. affinis*, Ruppell, (*Neue Wirbelth. Fische*, 49, Tab. 14, Fig. 1.) the present also differs but slightly; in *affinis* the head is $\frac{1}{4}$ of the total length, and the pectorals equal the length of the head: both are therefore shorter than in the present. The first dorsal spine is $\frac{1}{3}$ of the fourth, the longest. In the present the first spine is $2\frac{1}{3}$ in the length of the third and fourth, which are of equal length. Single individuals occur at all seasons at Pinang. They are eaten by the natives.

(3718) *Caranx leptolepis*, Kuhl. and Van Hasselt.

Syn. Caranx leptolepis, Cuv. and Val. IX. 63.
Caranx mertensii Cuv. and Val. IX. 64.

Head above and back steel blue; from above the orbit to the caudal a broad gamboge band; the rest of the body shining silvery; dorsal and caudal fins gamboge, the rest white. Iris silvery, blue towards the orbit. In some individuals a large bluish black spot on the upper part of the opercle. D 8—1/25 or 26, C $17\frac{6}{6}$, A 2—1/22 or 23, V 1/5, P 20, Br. VII. Inhabits *Sea of Pinang*, *Singapore*, Java, Manilla. Total length: $4\frac{4}{8}$ inch. The length of the head is $3\frac{1}{3}$ in the total, measured to the centre of the posterior margin of the caudal; the depth at occiput is $\frac{1}{6}$ less than the length. The diameter of the orbit, which is surrounded by a very narrow adipose fold, is $\frac{1}{3}$ of the length of the head. The lower margin of the opercle is straight. The snout is uncommonly protractile; the teeth of both jaws are excessively minute, so as to be barely perceptible to the touch. The very slight arch of the lateral line terminates opposite the middle of the second dorsal; the anterior part of the rest is covered by minute scales, which do not preceptibly increase in size till opposite the posterior third of the second dorsal, from whence may be counted 25 such. None of these scales exceed $\frac{1}{16}$ of the greatest vertical diameter of the body, which equals the length of the head. The length of the falcated pectorals also equals that of the head. M.M. Cuvier and Valenciennes describe *C. mertensii* as merely differing by the absence of the black opercular spot. At Pinang, where the fish is uncommon, individuals occur with and without the spot, in forms and colours so exactly like, as to leave no doubt about their identity.

C.—With trenchant profile, forming a segment of a circle; plates exclusively on the straight portion of the lateral line; pectorals falciform; in front of the first dorsal an immoveable horizontal spine, often hid in the integuments.

(3719) *Caranx forsteri*, Cuv. and Val.?

Syn. Scomber hippos, Lin. apud Forster?
Caranx forsteri, Cuv. and Val. IX. 107?

Young. Head above and back golden green, lighter on the sides; rest of the body shining silvery; abdomen with mother-of-pearl reflections; at the angle of the opercle a very faint bluish black spot; first dorsal minutely dotted with brown, so as to appear pale grey; ventrals and anal white; pectoral, caudal and second dorsal yellowish, the point and margin of the latter, and the posterior margin of the caudal minutely dotted with brown, so as to appear greyish. Iris

silvery, bluish black towards the orbit. D 8—1/20 or 21, C 17/7, A 2—1/15, 16 or 17, V 1/5, P 19, Br. VII. Inhabits *Sea of Pinang*. Total length: 4⅛ inch. The length of the head is a little less than 3½ in the total, measured to the centre of the posterior margin of the caudal fin; the depth at occiput equals the length. The diameter of the orbit is 3¼ in the length of the head. The infraorbital is longer than broad: its greatest breadth, along the superior margin equalling ½ the diameter of the orbit. The arched, very slightly undulating, portion of the lateral line terminates opposite the fifth or sixth ray of the second dorsal; the straight portion is covered by 30 to 31 plates, none of which exceed about ⅙ of the greatest diameter of the body, which is 3¼ in the total length of the body. The length of the falcated pectorals equals that of the head. Single individuals occur at Pinang at all seasons. They appear nearest to correspond to the description of *C. forsteri*.

(3720) *Caranx malabaricus*, (Bloch-Schneider.)

Syn. Scomber malabaricus, Bloch-Schn. p. 31. Russell, CL. Tallam Parah.
Caranx malabaricus, Cuv and Val. IX. 121.
Caranx malabaricus, Richardson, Report, 1845, 275.

Head above and back pale silvery sea green; sides of the head and body shining silvery with blue reflections; abdomen white; at the upper part of the opercle a bluish black spot; pectorals, second dorsal and caudal yellowish white, the two latter sparingly dotted with black towards the margin; anal and ventrals white; first dorsal hyaline. Iris silvery, minutely dotted with brown; upper orbital margin bluish black. D 8—1/22, C 17/7, A 2—1/18, V 1/5, P 20, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Coromandel, Bay of Bengal, Red Sea, China Sea. Total length: 8 inch. The length of the head is 3⅓ in the total, measured to the centre of the posterior margin of the caudal; the depth at occiput equals the length. The transversal diameter of the orbit is a little less than ⅓ of the length of the head. The teeth of both jaws, of the vomer and the palatals are velvety, but those on each side of the symphysis of the jaws are a little longer than the rest. The tongue is very small, linear, and with the exception of the apex, covered with velvety teeth. The arched portion of the slightly undulating lateral line terminates opposite the posterior third of the second dorsal; the straight portion is covered by 35 to 36 plates, none of which exceeds 1/10 of the greatest vertical diameter of the body, which is about 2½ in the total length. The pectorals equal the length of the head. Single individuals occur at Pinang at all seasons, and are eaten, fresh or dried, by the natives.

(3721) *Caranx nigripes*, Cuv. and Val.

Syn. Russell CLII. Mais Parah.
Caranx nigripes, Cuv. and Val. IX. 122.
Caranx nigripes, Richardson, Report, 1845. 275.
Caranx nigripes. Bleeker; Verh. Batav. Gen. XXII. 4.

Head above and back pale silvery blue or green; sides of the head and body shining silvery with rose coloured reflections; abdomen white: on the upper part of the opercle an indistinct bluish black spot; base and anterior margin of ventrals white, rest greenish black, and between these fins a black spot; first dorsal greyish, minutely dotted with black; the rest of the fins white, the second dorsal and caudal minutely dotted with black towards the margin; at the symphysis of the lower jaw a black spot; branchiostegous rays and membrane silvery white, the latter broadly brimmed with black between the four lower rays. Iris silvery, upper orbital margin bluish black. D 8—1/21 or 22, C 17/6, A 2—1/18, 19 or 20, V 1/5, P 19, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Coromandel, Bay of Bengal, Java, Balli, Madura, China Seas. Total length: 6 inch. The length of the head is 3½ in the total, measured to the centre of the posterior caudal margin; the depth at occiput exceeds by ⅙ the length. The transversal diameter of the eye is 3¼ in the length of the head. The greatest vertical diameter of the body is 2⅛ in the total length. The horizontal, immovable, spine in front of the first dorsal, is rather strong, with the point free. The arched portion of the lateral line terminates opposite the fifth ray of the second; the straight portion is covered by about 36 or 37 slightly pointed plates, none of which exceeds 1/20 of the greatest diameter of the body. The length of the falcated pectorals is 3⅕, that of the ventrals is 4⅕ in the total. The length of the ventral spine is 2½ in the nearest ray. The point of the second dorsal and anal fin is 3⅛ in the greatest vertical diameter of the body. Behind the eyes appear some indistinct scales; the cranial crest, the rest of the head and the thorax are scaleless; the rest of the body is covered by small orbicular, somewhat deciduous scales. This species is at all times excessively numerous in the Straits of Malacca and the Bay of Bengal. The natives eat it in its fresh and dried state.

(3722) *Caranx atropus*, (Bloch-Schneider).

Syn. Brama atropus, Bloch-Schneider, 98, Pl. 23.
Olistus atropus, Cuv. and Val. IX. 141.

D 8—1/21, C 17/6, A 2—1/17, V 1/5, P 19, Br. VII. Inhabits *Sea of Pinang*, Tranquebar. Total length: 7½ inch. In proportions, number of fin rays and colours this fish exactly resembles *Caranx nigripes*, from which it merely differs in having the 6th, 7th, 8th, 9th, 10th,

11th, and 12th rays of the second dorsal longer than the rest, and the elongated part not connected by the membrane. The 8th and 9th are the longest, each being about 2½ in the greatest vertical diameter of the body. All the elongated rays, although filamentous, are distinctly branched, which consequently excludes the fish from the genus *Olisthus*. *Olisthus, Cuv.* (R. A 1829.) Differs from *Caranx*, (*Citula*) in having the middle rays of the second dorsal not branched, but merely articulated, and each elongated into a filament. The elongated part, as well as the half of the membrane in front of each ray, is minutely dotted with black. However erroneous Bloch's description and figure of *Brama atropus* may be, there seems to be no reason to doubt that a specimen of the present fish was his original. M.M. Cuvier and Valenciennes observe that the specimen now extant, marked by Bloch: *Brama atropus*, (his specimen of *Caranx nigripes* is labeled: *Brama melampus*), is nothing but *Caranx nigripes*. Mutilation of the delicate filaments of *C. atropus* would indeed render it indistinguishable from *C. nigripes*. A single individual of the present was observed at Pinang in June, 1844, and it remains to be ascertained if the elongation of some of the dorsal rays is more than an individual distinction. Dr. Ruppell obtained in the Red Sea a specimen of his *Citula ciliaria* (Syn. *Olistus? rupellii*, Cuv. and Val.) which had the middle rays of both the second dorsal and of the anal fin elongated filamentous, and he therefore thinks it possible that the fish is identical with *Olistus malabaricus*, Cuv. and Val. (Neue Wirbelth. Fische: p. 50).

(3723) *Caranx armatus*, (Ruppell).

Syn. Sciæna armata, Forskal Fauna Arab. p. 53 No. 68?
Sciæna armata, Linne, Syst. 1306?
Russell CLI. Tchawil Parah. (*Young*).
Citula armata, Ruppell: Atlas, 103.
Caranx citula (cirrhosus Ehrenb.) Cuv. and Val. IX. 126 Pl. 250.
Caranx armatus, Cuv. and Val. IX. 127.
Caranx ciliaris Cuv. and Val. IX 129. (*Young*).
Citula armata, (Syn. Caranx cirrhosus), Ruppell Neue Wirb. Fische 50.
Caranx ciliaris. Temm. et. Schl. Fauna Japon. Pisc. 112.
Caranx ciliaris, Richardson Report, 1845. 276.

Young. Head above and back pale sea green or bluish green; sides of the head and of the body beneath the lateral line mother-of-pearl with pale rose coloured reflections: abdomen white; an indistinct black spot at the upper part of the opercle; first dorsal hyaline minutely dotted with black; second dorsal yellowish white the elongated point and the upper margin minutely dotted with black; caudal yellowish white; marginal half minutely dotted with black; anal and pectorals white; base and anterior margin of the ventrals white, rest pale greenish grey, minutely dotted with brown. Iris silvery, upper orbital half greenish black. D 8—1/21, C 17⅗ A 2—1/16 or 17, V 1/5, P 19, Br VII. Inhabits *Sea of Pinang, Singapore*, Seas of China and Japan, New Guinea, Java, Coromandel, Red Sea, Indian Ocean. Total length: 4⅝ inch. The length of the head is 3⅓ in the total, measured to the centre of the caudal fin: the depth at occiput exceeds by ¼ the length. The diameter of the orbit is ⅓ of the length of the head. The greatest vertical diameter of the body, in front of the second dorsal, is 2¼ in the total length. The arched portion of the lateral line does not abruptly become straight; it straightens a little in front of and opposite the third posterior part of the second dorsal, and is covered by about 24 plates, none of which exceeds ⅓ of the greatest vertical diameter of the body. The elongated first dorsal ray exceeds by about ¼ the greatest vertical diameter of the body; the first anal ray scarcely exceeds ⅔ of the first dorsal, but is frequently less. The point of the horizontal spine, in front of the first dorsal fin, is exposed. The length of the falcated pectorals is ⅓ of the total length; the ventrals slightly exceed ⅓ of the pectorals. The species is of uncommon occurrence at Pinang. It corresponds exactly to Russell's No. CLI. (*Caranx ciliaris*, Cuv. and Val.) which would appear to be the young of *Citula armata*, which Dr. Ruppell considers to be identical with *Caranx citula* (*cirrhosus*, Ehrenb.) Cuv. and Val. The description of the latter affords no specifically distinguishing characters.

(3724) *Caranx oblongus*, Cuv. and Val.

Syn. Caranx oblongus Cuv. and Val. IX.

Young. Head above and back pale yellowish green; sides of the head and body beneath the lateral line shining silvery; abdomen white; first dorsal hyaline, sparingly dotted with brown; second dorsal and anal hyaline, the marginal half minutely dotted with brown, the elongated points of the fins bright yellow; ventrals and caudal yellow, the margin of the latter minutely dotted with black; pectorals white. Iris golden light green; upper half of orbital margin bluish black. D 8—1/22, C 17/7, A 2—1/19, V 1/5. P 21, Br. VII. Inhabits *Sea of Pinang*, Vanicolo, Oualan. Total length: 5⅝ inch. The length of the head is ⅓ of the total, measured to the centre of the posterior margin of the caudal; the depth at occiput slightly exceeds the length of the head, of which the diameter of the orbit is ⅓. Of the velvety teeth those of the symphysis of both jaws are somewhat stronger than the rest. The greatest vertical diameter of the body in front of the second dorsal is 2½ in the total length, measured to the centre of the posterior margin of the caudal. The lateral line is slight-

ly arched, following the profile of the back it terminates opposite the second third of the dorsal. The straight portion is covered by 40 strongly keeled plates, none of which exceed $\frac{1}{8}$ of the greatest vertical diameter of the body. The point of the horizontal spine in front of the first dorsal is exposed. The elongated anterior ray of the second dorsal exceeds by $\frac{1}{7}$ the greatest vertical diameter of the body, of which the anterior ray of the anal is but $\frac{1}{2}$. The falcated pectorals equal the lobes of the caudal, and are $2\frac{1}{2}$ in the total length. The ventrals are $\frac{1}{2}$ of the pectorals. A single individual occurred at Pinang in September, 1843.

(3725) *Caranx Speciosus*, (Forskal.)

Syn. Scomber speciosus Forskal, Fauna Arab 54 No. 70.
Scomber speciosus Linne Syst. 1332.
Lacepede III. Tab. 1 Fig. 1.
Russell, CXLIX. Poloosoo Parah.
Scomber speciosus Shaw. IV. 603.
Caranx a six bandes. Quoy et Gaim. Tab. 65 Fig. 4.
Caranx speciosus Ruppell Atlas, 96.
Caranx speciosus. (Syn. C. petaurista: Isid. Geoff. Eg. Tab. XXV. Fig. 1. *Adult.*) Cuvier, R. A. II. 209 (1)
Caranx speciosus, Cuv. and Val. IX. 130.
Caranx speciosus Ruppell: Neue Wirbelth. Fische 45.
Zonichthys subcarinata. Swainson: II. 248.
Caranx speciosus Bleeker: Verh. Batav. Gen. XXII. 4.

Ground colour citrine or king's-yellow with a bluish black oblique band from the centre of the orbit of the occiput; a second from the occiput vertically over the posterior margin of the opercle: a third narrow line from in front of the first dorsal to a little below the lateral line; a fourth broad band from the middle of the first dorsal to abdomen: a fifth narrow line from between the dorsals; a sixth broad band from the anterior part of the second dorsal; a seventh narrow line from the middle; an eighth broad band from the posterior part; and a ninth narrow line from the termination of the second dorsal: the posterior three alternate bands and lines reaching the abdomen; in some a bluish black spot at the root of the pectoral; branchiostegous rays and membrane, the two spines in front of the anal and the ventrals white; the rest of fins citrine, the dorsals minutely dotted with black, the points of the caudal and the posterior margin black. Iris golden citrine, upper orbital margin bluish black. D 7—1/19 or 20, C $17\frac{1}{2}$, A 2—1/14 or 16, V 1/5, P 22, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, New Holland, Vanicolo, Isle of France, Red Sea, Trincomalie, Coromandel, Java, Madura. Total length: 9 inch. The length of the head is $3\frac{1}{3}$ in the total, measured to the centre of the posterior margin of the caudal; the depth at occiput equals the length. The diameter of the orbit is $\frac{1}{4}$ of the length of the head. In individuals not exceeding $3\frac{1}{2}$ inches in length, velvety teeth may be felt on each side on the symphysis of the upper jaw; on each side of the symphysis of the lower they may distinctly be seen, and a single series of from 10 to 12 rather distant teeth appear across the vomer. In an individual 9 inches in length no teeth appeared except a small, yet distinct, one on each side of the symphysis of the lower jaw. The greatest vertical diameter of the body, in front of the second dorsal, is $\frac{1}{3}$ of the total length. The arched portion of the lateral line terminates, but not abruptly so, a little in front of and opposite the middle of the second dorsal fin. The straight portion is covered by upwards of 34 slightly keeled plates, of which none of the posterior 12, the largest, exceeds $\frac{1}{2\frac{1}{4}}$ of the greatest vertical diameter of the body. The length of the falcated pectorals equals that of the head. Single individuals occur at Pinang at all seasons. They are eaten by the natives.

Genus SCYRIS, *Cuvier*, 1829. Differs from *Caranx* by a more elevated, trenchant profile; first dorsal entirely hid; second dorsal with some of the rays elongated, filamentous.

(3726) *Scyris indicus*, Ruppell.

Scyris indicus, Ruppell: Atlas, 128, Tab. 33 Fig. 1. (*Young.*)
Scyris indica, Cuv. and Val. IX. 145, Pl. 252. (*Adult.*)
Scyris indicus, Ruppell: Neue Wirbelth. Fische 51.
Scyris ruppelli, (*Young*) } Swainson, II.
Scyris indicus, (*Adult*) } 251.
Scyris indica, Richardson, Report, 1845, 276.

Head above and back blackish silvery; cheeks and opercles shining silvery, the latter minutely and sparingly dotted with brown; at the upper part of the posterior margin of the opercle a small intensely black spot; the rest of the body silvery satin, abdomen sparingly dotted with brown; fin-rays and membranes yellowish white; upper margin of the second dorsal and posterior margin of the caudal minutely dotted, so as to appear blackish; root of the pectoral silvery. Iris silvery, upper orbital half bluish black. D 1/'9, C $17\frac{1}{6}$, A 1/16, V 1/5, P 19, Br. VII. Inhabits *Sea of Pinang*, Java, Pondicherry, Red Sea, China Seas. Total length: 1 foot 9 inch. The length of the head is $3\frac{1}{3}$ in the total, measured to the centre of the posterior margin of the caudal; the depth at occiput is but $\frac{1}{3}$ of the total length. The diameter of the orbit is $\frac{1}{4}$ of the length of the head. In both jaws appears two or three series of small, but strong, conical teeth resembling those of some *Sparoids*; those on each side of the symphysis are larger than the rest. The vomer presents a few similar, but the small, oblong, tongue is covered with card-like

teeth. The greatest vertical diameter of the body, in front of the dorsal fin, is $2\frac{2}{3}$ in the total length. Each of the small scales composing the lateral line has a central longitudinal tube, from the posterior part of which branch off two smaller ones: one upwards and backwards, the other downwards and backwards. The arched, somewhat undulating portion of the line terminates opposite the middle of the dorsal fin. The straight portion consists mostly of small scales, but towards the termination of the dorsal the posterior eleven gradually enlarge and become sharply keeled; the three or four last, although the largest, do not exceed $\frac{1}{2\frac{1}{2}}$ of the greatest vertical diameter of the body. In the adult the cranial crest is very large and arched, like that observed in *Platax arthriticus*, but the posterior part, from opposite the opercle, is not contiguous, but consists of three separate, gradually decreasing, egg-shaped pieces of bone. Behind the last, lie six successive pieces, entirely hid under the integuments, and resting on the interspinals. The anterior undulating dorsal ray is the longest, slightly exceeding the length of the head. This, as well as the three succeeding, gradually decreasing ones, are undivided; the fifth and sixth are branched like the following, but their anterior branch is undivided and slightly elongated. The anterior anal ray equals in length the corresponding dorsal, and is as well as the second undivided. In front of the anal fin lie two small distant spines entirely concealed under the integuments. The length of the falcated pectorals is $\frac{1}{5}$ of the body, not including the caudal; that of the ventrals a little less than $\frac{1}{6}$ of the pectorals. Single individuals are of very rare occurrence at Pinang.

Genus GALLICHTHYS, *Cuv. and Val.* 1833. Body high and compressed: profile much elevated; ventrals elongated; caudal furcated; first dorsal fin very low or reduced to a series of short spines; anterior rays of second dorsal and anal excessively elongated.

(3727) *Gallichthys major.* Cuv. and Val.

Syn. Russell, LVII. Gurrah Parah.
Gallichthys major, Cuv. and Val. IX 168, Pl. 254.
Blepharis gallichthys, Swainson, II. 250.
Gallichthys major, Richardson Report, 1845, 271.

Head above and back blackish silvery; cheeks and opercles shining silvery; at the upper part of the latter an indistinct bluish spot; rest of the body silvery satin; fin-rays and membranes yellowish white; elongated portion of the dorsal and anal, upper margin of the dorsal and posterior of the caudal minutely dotted with black; dorsal and anal filaments, and ventral fins black. Iris silvery, upper orbital half bluish black. D 6—1/18 or 19, C $17\frac{1}{2}$, A 2—1/16, V 1/5, P 19, Br. VII. Inhabits *Sea of Pinang, Singapore,* Coromandel, Moluccas, China Sea. Total length: 6 inch. The length of the head is $\frac{1}{4}$ of the total, measured to the centre of the posterior margin of the caudal; the depth at occiput is nearly double the length of the head. A narrow band of velvety teeth appears in both jaws and on the vomer. The diameter of the eye is $\frac{1}{3}$ of the length of the head. The greatest vertical diameter of the body is $1\frac{1}{2}$ in the total length. The lateral line in its component scales, and its course exactly resembles that of *Scyris indicus*. The length of the anterior ray and its hairlike filament, of the second dorsal, anal, and ventral fins equals the length of the body; it is, however, liable to individual variations. The four anterior rays of the second dorsal are undivided, and as well as the five succeeding branched rays, terminate in gradually decreasing hairlike filaments. The two anterior anal rays are undivided, and as well as the third, which is branched, terminate in similar filaments. The anterior ventral ray is undivided, and, as well as the second, which is branched, filamentous. The length of the falcated pectorals and of the caudal lobes is $2\frac{2}{3}$ in the total. Single individuals are rarely seen at Pinang.

Genus SERIOLA, (*Risso,*) *Cuvier* 1829. Two dorsals, no spurious fins; tail without keel or crests; jaws, vomer and palatals with velvety or card-like teeth. Differs from *Caranx* by the not mailed lateral line; from *Lichia* by the membrane uniting the spines of the first dorsal.

(3728) *Seriola binotata*, Cuv. and Val.

Syn. Seriola binotata, Cuv. and Val. IX. 215.

Head above, back and sides to the lateral line yellowish green; sides of the head and body beneath the lateral line greenish yellow, abdomen bluish white or green; dorsals greenish yellow; a black vertical band above the eye, a second broader from occiput over the opercle; a third from between the second and fourth spine of first dorsal down towards the pectoral; a fourth from the point of second dorsal to the side below the lateral line: a fifth from the middle of the second dorsal to the lateral line; a sixth from the posterior part of the second dorsal; a seventh in front of the upper half of the root of the caudal; between the bands some round and irregular black spots; caudal yellow with a round black spot in the centre and an oval over each lobe, the point of which is yellowish white; anal light bluish green, lower half black, anterior and posterior angle yellowish white; ventrals light bluish green, posterior half black, point of anterior ray yellowish white; pectorals pale yellow. Iris light golden green, orbital margin blackish. D 7—1/32 or 33, C $17\frac{1}{2}$, A 2—1/15, 16 or 17, V 1/5, P 19, Br. VII. Inhabits *Sea of Pinang, Singapore,* Pondicherry, Bay of Bengal. Total Length: $4\frac{4}{5}$ inch. The length of the head is $3\frac{1}{2}$ in the total, measured to the centre of the posterior margin of the caudal;

the depth at occiput is a little less than the length of the head. The diameter of the eye is $\frac{1}{4}$ of the length of the head. The forehead between the eyes is arched, not trenchant. The angle of the mouth is opposite the posterior margin of the orbit. The card-like teeth of the jaws, vomer and palatals are rather large, recurvous; those of the tongue velvety. The greatest vertical diameter of the body, in front of the first dorsal, slightly exceeds the length of the head. No immoveable spine is perceptible in front of the first dorsal fin. The anterior third of the lateral line is a little arched, the rest nearly straight. The first dorsal, is small: its height but $\frac{1}{3}$ of the greatest vertical diameter of the body; the point of the second dorsal is more than double the height of the former. The length of the ventrals equals that of the head; the anterior half of the fifth ray is connected to the abdomen by a membrane. The length of the pectorals is $\frac{1}{6}$ of that of the body, the caudal not included. The caudal lobes are $\frac{1}{4}$ of that distance. Single individuals occur rarely at Pinang. This species greatly resembles *Seriola nigrofasciatus* (Ruppell,) [Syn. Nomeus nigrofaciatus, Ruppell, Atlas, 82 Pl. 24, Fig. 1. — Seriola ruppelli, Cuv. and Val. IX. 216.] From which it, however, may at once be distinguished by the remarkably shorter distance between the first and second dorsal.

Genus LACTARIUS, *Cuv. and Val.* 1833. (Platylepis, *Swainson* 1839.) Differs from *Seriola* in having one or two long arched teeth on each side of the symphysis of the upper jaw; in having a single series of fine teeth in the lower, and on the symphysis one or two longer ones; and in the absence of free spines in front of the anal fin.

(3729) *Lactarius delicatulus*, Cuv. and Val.

Syn. Scomber lactarius, Bl.-Schn. 31, No. 26. Russell CVIII, Chundawah.
Seriola lactaria, Cuv. R. A. II. 206,
Lactarius delicatulus, Cuv. and Val. IX. 238. Pl. 261.
Platylepis lactaria, Swainson, II. 247.
Lactarius delicatulus, Richardson Report 1835, 272.
Lactarius delicatulus, Bleeker: Verh. Bat. Gen. XXII. 4.

Head above, back and sides to the lateral line greenish grey or lead coloured; the rest shining silvery; a black spot at the upper part of the posterior margin of the opercle; fins hyaline, marginal half of dorsals and caudal minutely dotted with black. Iris silvery, upper half of orbital margin black. D 8—1/21 or 22, C $17\frac{?}{?}$, A 3/25, 26 or 27, V 1/5, P 16, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore,* Coromandel, Bay of Bengal, mouths of the Ganges, Malabar, Java, Madura. Total length: $4\frac{1}{3}$ inch. The length of the head is $\frac{1}{4}$ of the total, measured to the centre of the posterior margin of the caudal; the diameter of the eye is $3\frac{1}{2}$ in the length of the head. The greatest vertical diameter, in front of the first dorsal equals the length of the head. The lateral line follows at the upper third of the body the outline of the back. The scales of the lateral line and the body are rather large, orbicular, very thin and deciduous. This species is excessively numerous at all seasons. It is eaten both fresh and dried.

Genus STROMATEUS, (*Artedi, Linne.*1748.) Ventral fins none; dorsal single with the spines hid in the anterior margin; vertical fins covered with scales.

(3730) *Stromateus niger*, Bloch.

Syn. Stromateus paru, Bloch Pl. 160.
Stromateus niger, Bloch Pl. 422.

Bawar or Bawal tumbak of the Malays.

Head above, back and sides dark greyish brown with blue reflections; cheeks, opercles and abdomen silvery light bluish grey or pale neutral tint; dorsal and anal silvery bluish grey, blackish towards the margin; pectorals and caudal yellowish light grey, edged with blackish. Iris silvery blackish or brownish blue. D 1/42 or 43, C $17\frac{?}{?}$, A 1/37 or 38, P 23 Br. VI. (VII?) Inhabits *Sea of Malayan Peninsula and Islands,* Chusan, Macao, Coromandel, Bay of Bengal, Bombay, Java, Celebes, Madura. Total length: 1 foot. The length of the head is $3\frac{1}{3}$ in the total, measured to the centre of the posterior margin of the caudal. The diameter of the eye is $\frac{1}{4}$ of the length of the head. In each jaw appears a single series of excessively minute teeth. The greatest vertical diameter of the body, from the middle of the point of the dorsal to the anal, is a little less than $\frac{1}{3}$ of the total length. The lateral line, at the upper third of the body, follows the outline of the back to a little in front of the dorsal, from whence it proceeds straight to the caudal. It is raised, like a thin cord; the tail is distinctly keeled. The dorsal fin is preceded by four or five, the anal by four short spines, which, however, are completely hid by the integuments. The length of the falcated pectorals is a little more than $2\frac{1}{2}$ in the total. The lobes of the caudal equal the length of the head. This species, "*the black pomfret,*" is at all seasons taken in abund-

ance in the Straits of Malacca, where, however, it is considered inferior to *Stromateus sinensis*, "*the white pomfret*." In dried state it is largely exported, and thus it appears in the bazars of Hindustan, which are chiefly supplied from Bombay.

(3731) *Stromateus sinensis*, Euphrasen.

Stromateus albus, Cantor, Ann. Nat. Hist. IX. 15.)
Stromateus atous, Richardson Report 1845, 273.
Bawar or Bawal chirmin of the Malays.

Young. Head above and back reddish brown; rest of the body and fins lighter silvery, with a mixture of ventral tint, lilac or blue; dorsal, anal, and caudal with the marginal half blackish; everywhere with brown dots of different sizes: the larger with a silvery point in the centre. *Adult*. Head above, back and sides to the lateral line deep neutral tint; rest of the body with a mixture of brownish grey with metallic reflection, lighter, silvery towards abdomen; everywhere dotted as the young; large patches of milk white naked skin, where the scales have disappeared; fins silvery grey, marginal half blackish; cavity of the mouth and tongue pale bluish grey with brown dots, silvery in the centre. Iris reddish silvery or copper-coloured, minutely dotted with brown. D 1/43 to 46, C 17/7, A 1/39 to 42, P 26 or 27, Br. VI. Inhabits *Sea of Malayan Peninsula and Islands*, Coromandel, Bay of Bengal, Macao, Chusan. Total length: 10 inch. The length of the head is 4½ in the total, measured to the centre of the posterior margin of the caudal. The diameter of the eye is a little less than ⅓ of the length of the head. The lower jaw projects a little beyond the upper: in both appears a single close series of excessively minute teeth. The thread-like lateral line, at the upper fifth of the body, follows the outline of the back to the termination of the dorsal fin, from whence it proceeds straight, along the upper third of the tail to the caudal. The scales of the body are small, orbicular and so deciduous that the fish generally appears with large patches of milkwhite naked skin. The greatest vertical diameter of the body, from the middle of the point of the dorsal to that of the anal fin, exceeds by ⅕ half the total length. The pectorals are broad, pointed but not falcated and project from the body; their length is 3½ in the total. The length of the broad triangular caudal lobes equals that of the head. Both the dorsal and anal fin are preceded by four spines completely hidden by the integuments. As in *Stromateus fiatola*, Linne, and in *S. argenteus* Bloch, the fleshy oesophagus is armed with numerous bony, barbed, spines or teeth. In the stomach of those examined appeared remains of fishes. This is par excellence the "*white pomfret*" of the Straits Settlements and Madras, "*pample blanche*" of Pondicherry. It is justly renowned for its flavour, but it requires to be freshly taken when used. In the Straits and on the Coromandel Coast it is abundant at all seasons. At the Sandheads in the Bay of Bengal, (21° N. L.) it occurs, but less numerously. Russell happened seldom to see this species and considered it very inferior to the "*black*" (*Stromateus niger*, Bloch) or "*white pomfret*," by which latter Russell means *Stromateus argenteus*, Bloch. (Russell p. 34.)

(3732) *Stromateus argenteus*, Bloch.

Syn. Stromateus argenteus, Bloch, Pl. 421.
Stromateus argenteus, Shaw IV. 110.

Stromateus securifer, Richardson Report 1845, 273.
Stromateus candidus, Bleeker: Verh. Bat. Gen. XXII. 4.

Head above back and sides to the lateral line neutral tint with purple reflections; sides of the head and body beneath the lateral line silvery grey, everywhere with minute black dots, disposed on the sides of the occiput, and the upper half of the body so as to produce alternate indistinct, blackish and silvery grey-undulating, irregular lines; on the upper part of the opercle an irregular black spot; abdomen silvery white; dorsal and anal silvery, minutely dotted with black so as to render the point and marginal half blackish; caudal and pectorals yellowish white, minutely dotted with black so as to make the posterior half and the margins blackish; cavity of the mouth and tongue as in *S. sinensis*. Iris silvery, minutely dotted with black. D 9—1/39 to 43, C 17/7, A 6—1/34 to 38, P. 25, Br. VI. Inhabits, *Sea of Malayan Peninsula and Islands*, Malabar, Coromandel, Bay of Bengal, Macao, Chusan, Java, Madura. Total length: 9 inch. The length of the head is 4½ in the total, measured to the centre of the posterior margin of the caudal. The diameter of the eye is 3½ in the length of the head. The muzzle is a rounded protuberance which

considerably projects beyond the mouth. Both jaws have a single close series of excessively minute teeth. The naked skin of the upper part of the head and the anterior part of the back is longitudinally wrinkled. The lateral line follows a similar course to that of *S. chinensis*, and the scales of the body are equally deciduous. The points of the dorsal and anal are more falcated and as well as the lobes of the caudal and the pectorals more elongated than in the former species. The length of the point of the anal, slightly exceeding that of the dorsal, equals the pointed pectorals which as well as the caudal lobes are $\frac{1}{3}$ of the total length. The greatest verticle diameter of the body between the commencement of the dorsal and anal fin, exceeds by $\frac{1}{4}$ half the total length. The dorsal fin is preceded by nine truncated processes of which each has one forwards and one backwards directed spine; the anal is preceded by six similar ones, differing, however, in having the longer spine pointing backwards. In young individuals these spines are much more distinct than in the adult, and in this stage the fish has been described as *Stromateus securifer.—Stromateus argenteus*, Euphrasen,—*Stromateus aculeatus*, Bloch-Schneider, is probably also the young of this species. In the adult fish the anterior two or three of the truncated dorsal processes are completely hidden by the integuments, and the rest are barely piercing the back, so as to be more readily felt than seen. Although they escaped the observation of Bloch, Russell correctly identified his No. XLII. *Tella Sandawa*, with Bloch's Pl. 421. In the Straits Settlements as well as at Madras, also, this species is denominated the "*white pomfret.*" In abundance and excellence it vies with *S. sinensis*.

(3733) *Stromateus cinereus*, Bloch.

Syn. Stromateus cinereus, Bloch Pl. 420.
Stromateus cinereus, Shaw IV. 109.
Russell XLV. Sudi Sandaweh.
Stromateus sudi, } Russell p. 35
Stromateus cinereus, }
Stromateus griseus, Cuv. R. A. II. 213 (?)
Stromateus griseus, Cuv. & Val. IX. 395.

Head above, back and sides to the lateral line lead grey; cheeks and opercles silvery, slightly dotted with black; an irregular black spot on the upper part of the opercle; sides beneath the lateral line silvery grey; abdomen silvery white; dorsal and anal silvery grey, minutely dotted with black; their elongated points margins blackish; caudal yellowish white, minutely dotted with black, margins and posterior part of the lobes blackish; pectorals buff, upper margin and posterior half minutely dotted with black; cavity of the mouth and tongue as in *S. sinensis*. Iris silvery, orbital half lead grey. D 7 or 8—1/39 to 41, C 17/7, A 5—1/32 to 39, P 23 to 25, Br. VI, Inhabits *Sea of Malayan Peninsula and Islands*, Coromandel, Bay of Bengal.

Length of the body..... 4 inch.
„ of the lower caudal lobe, ... 4 „
Total length: 8 inch.

The length of the head is $\frac{1}{4}$ of the total, measured to the centre of the posterior margin of the caudal. The diameter of the eye is $\frac{1}{3}$ of the length of the head. The muzzle forms a large rounded protuberance projecting over the mouth. Each jaw has a close series of excessively minute teeth. The lateral line is situated as in *S. sinensis* and *argenteus*. The scales of the body are small, orbicular and so deciduous that the fish generally appears scaleless. The truncated processes preceding the dorsal and anal fin resemble those of *S. argenteus*, from which the present may readily be distinguished by the far greater elongation of the lower lobe of the caudal, and of the falcated point of the anal fin. The falcated point of the dorsal equals the length of the pointed pectorals, which are $2\frac{2}{3}$ in the total length. The upper caudal lobe is but $\frac{1}{2}$ of the lower, which equals the length of the body, the caudal not included. The length of the falcated point of the anal fin in some individuals equals the lower caudal lobe, in others it is but $\frac{2}{3}$ of the latter. The greatest vertical diameter of the body, between the commencement of the dorsal and anal fin, exceeds by $\frac{1}{3}$ half the total length. At Pinang this species is as abundant as the preceding, but probably from its inferior size it is considered somewhat inferior in quality. At the Sandheads it occurs rarely.

Genus CYRTUS, *Bloch.* 1787. Body compressed; back greatly elevated with several small trenchant blades in front of the dorsal; between the ventrals on the pelvis a horizontal, backwards directed spine; scales excessively minute, transparent; ribs dilated, convex, forming rings in contact with each other and producing a conical cavity.

(3734) *Cyrtus indicus*, Bloch.

Kurtus cornutus, Cuv. and Val. IX. 226. (*Male?*)
Kurtus blochii, Swainson II. 253.
Kurtus blochichiü, Bleeker: Verh. Bat. Gen. XXII. 4.

Head above and body flesh-coloured, hemitransparent; back minutely and closely dotted with black, forming immediately behind the occiput a large rounded spot, from which in some

(the males?) projects the black, downwards arched, horn-like process; opercles and jaws silvery, with steel blue reflections; abdomen silvery with rose-coloured, lilac and golden reflections; pectorals and ventrals whitish, the rest of the fins pale reddish or whitish yellow, minutely dotted with black. Iris silvery, upper orbital margin blackish. D 8—2/13, C 17$\frac{1}{2}$, A 2/33 or 34, V 1/5, P 23, Br. VII. Inhabits *Sea of Malayan Peninsula and Islands*, Java, Madura, Coromandel, Sandheads. Total length: 5 inch. The length of the head in a straight line from the symphysis of the lower jaw, is $\frac{1}{4}$ of the total, measured to the centre of the posterior margin of the caudal, but taken obliquely upwards to the membranous angle of the opercle, it is but $\frac{1}{4}$ of the total, and equals the depth at occiput. The diameter of the eye is $\frac{1}{4}$ of the former length of the head. In each jaw is a band of card-like teeth: in the upper immediately under the symphysis is a naked excavated space, which receives from the lower a corresponding protuberance, covered with teeth; on the vomer and the palatals appears a single series of excessively minute velvety teeth. On the inferior margin of the preopercle appear three strong backwards arched spines, of which the posterior is the longest and somewhat removed from the others. The angle of the opercle projects far back, and is excessively thin, membranous, supported by four or five backwards radiating rays, the points of which are exposed. In those, supposed by Cuvier to be males, projects immediately behind the occiput a horn-like, compressed process, broad at the base, somewhat attenuated, but truncated at the apex. It is arched, placed horizontally, with the apex bent downwards. On the upper margin, close to the apex appear four minute spines. The two first dorsal spiny processes immediately behind the horn-like one, are very minute, triangular, with the point directed backwards; the third is truncated with a minute spine in front and behind; the fourth is much larger and consists of a forwards directed spine; the succeeding four spines gradually increase and are all directed backwards. The dorsal fin is preceded by two spines of which the anterior is $\frac{1}{4}$ of the second, which again is $\frac{1}{2}$ of the length of the first ray. The greatest vertical diameter of the body, in front of the first dorsal ray, is $\frac{1}{3}$ of the total length. Each of the broad, excavated ribs, from the third to the fifteenth vertebra, serves to form a conical, funnel-shaped cavity, very pointed towards the tail. The broad truncated lower extremity of each rib is striated, so as to appear as if fringed. The stomach is a rounded, rather capacious sac, generally expanded by remains of *Crustacea*; the liver is small, divided in two lobes; the gall bladder and the spleen excessively minute. The narrow intestinal canal forms two circumvolutions: its length is about $\frac{2}{3}$ of the length of the fish. In the Straits of Malacca and the Bay of Bengal as far as the mouths of the Ganges, it is excessively numerous at all seasons. Individuals with the horn-like process are far less numerous than those without it. Large quantities are dried, and consumed by the natives of India. Plate 277 of Cuvier and Valenciennes represents the fish much too red.

Genus EQUULA, *Cuvier* 1817. Body compressed; dorsal undivided; snout greatly protractile; edges of back and abdomen dentated along the fins.

(3735) *Equula caballa*, Cuv. and Val.

Syn. Scomber equula, Forskal, Faun. Arab, 58, No. 77.
Centrogaster equula, Linne: Syst. 1337.
Cæsio poulain, Lacep. III. 90.
Russell LXII. Tottah Karah?
Scomber equula, Shaw, IV. 596.
Equula caballa, Cuv. and Val. X. 73.
Equula caballa, Ruppell: Neue Wirbelth, Fische, 51.
Equula caballa, Bleeker: Verh. Bat. Gen. XXII. 5.

Head above and back silvery pale green, minutely dotted with black; the rest of the head and body shining silvery; muzzle above greenish grey, minutely dotted with black; dorsal and anal spines pale silvery irridescent, and as well as their membranes sparingly dotted with black; the base of the dorsal and anal membrane pale reddish yellow, the rest hyaline, the margin of the dorsal blackish; caudal yellowish white, minutely dotted with black, so as to render the posterior margin blackish, ventrals white, reddish yellow at the base and with a few black dots; pectorals hyaline, blackish silvery outside along the root, on the innerside and in axilla black. Iris silvery, orbital half blackish. D 8/16 or 7/17, C 17$\frac{1}{2}$, A 3/14 or 15, V 1/5, P 18 or 19, Br. V. Inhabits *Sea of Pinang*, *Sngapore*, Red Sea, Bombay, Malabar, Guam, Coromandel, Java, Sumbava, Madura. Total length: 6 inch. The length of the head is 3$\frac{2}{3}$ in the total, in the centre of the caudal margin; but with the muzzle protracted it slightly exceeds $\frac{1}{3}$ of the total. The diameter of the eye is $\frac{1}{3}$ of the length of the head. The narrow band of fine flexible teeth in the jaws, is almost hid by the fleshy lips. The lower part of the protracted muzzle is considerably arched downwards. The greatest vertical diameter of the body, in front of the dorsal fin, is $\frac{1}{2}$ of the total length. The second dorsal spine is broad, sabre-like, with a sharp edge, and on each side with a narrow longitudinal furrow. The second anal is shorter, but of the same shape. The anterior margin of the third and fourth dorsal, and of the third anal spine is toothed like a saw. Both the dorsal, anal, and ventral spines have the posterior margin transversely striated, a structure also observed in some species of the Genera *Apogon*, Lacep. and *Chanda*, Buchan, Ham. The succeeding

species of *Equula* present the same structure of these organs. The length of the second dorsal spine equals that of the head, or $\frac{1}{2}$ of the greatest vertical diameter of the body; the third dorsal is $\frac{1}{3}$ shorter than the second. The second anal spine is even broader than the second dorsal, but shorter, its length but slightly exceeding that of the third dorsal. The third anal is $\frac{2}{3}$ of the second. In *Equula edentula* (Bloch) (Syn. *Scomber edentulus*, Bloch.—*E. ensifera*, Cuv. and Val.) the two spines are of nearly equal length. At Pinang single individuals are of rare occurrence.

(3736) *Equula bindus*, Cuv. and Val.

Syn. Russell LXIV. Bindoo Karah.
Equula bindus, Cuv. and Val. X. 78.

Young. Head above and back silvery pale green, minutely dotted with black, so as to form a blackish line along the base of the dorsal; rest of the body shining silvery; upper part of opercle steel blue; dorsal fin hyaline, edged with black, upper third of second, third, fourth and fifth dorsal spines bright orange; caudal pale yellowish, minutely dotted with black, posterior margin blackish; anterior third of anal bright yellow, the rest hyaline; ventrals and pectorals whitish; inside of the mouth and gill-covers dotted with black. Iris silvery, orbital half blackish. D 8/16, C $17\frac{1}{7}$, A 3/14, V 1/5, P 15, Br. V. Inhabits *Sea of Pinang*, Coromandel. Total length: 3 inch. The length of the head is $3\frac{1}{3}$ in the total to the centre of the caudal margin; when the muzzle is protracted, it is $\frac{1}{3}$. The latter projects horizontally, forming a short truncated, cone. In both jaws appear a single series of excessively fine setaceous teeth. The diameter of the eye is $\frac{1}{3}$ of the length of the head. The two small spines above the anterior part of each orbit are strongly marked. The upper margin of the orbit is very finely toothed, but all the cranial crests are smooth. Russell's remark, that the back before the dorsal fin feels serrated to the finger, must therefore refer to the upper margin of the orbit. Between the interparietal crest and the first dorsal spine appears a smaller interspinal crest, the apex of which, however, does not in this more than in the other species penetrate the integuments. The greatest vertical diameter of the body, in front of the dorsal fin, is $\frac{1}{2}$ of the total length. The second dorsal spine is $\frac{1}{7}$ of the latter, or $\frac{2}{3}$ of the greatest vertical diameter; the third dorsal spine is but little shorter. The second anal spine equals in length the second dorsal, but it is a little less broad; the third anal is $\frac{3}{4}$ of the second. The ventral fins are remarkably short; their length equals the diameter of the eye; their spine is distinct, but slender. A single individual was observed at Pinang in April 1844.

(3737) *Equula splendens*, Cuvier.

Syn. Russell LXI. Goomarah Karah.
Equula splendens, Cuvier R. A. II. 212 (1).
Equula gomorah, Cuv. and Val. X. 80.
Equula gomora, Ruppell, Neue Wirb. Fische. 51.

Head above and back pale golden green, minutely dotted with black, forming a blackish line along the base of the dorsal fin; rest of the body silvery satin; the muzzle minutely dotted with black; a little above the lateral line an arched pale reddish line joining the posterior third of the lateral, which itself above borders a broad longitudinal pale reddish band; cheeks and opercles shining silvery; membrane of dorsal hyaline, the upper half between the second and sixth spine black; the rest edged with black; caudal pale reddish yellow, minutely dotted with black; anal pale reddish yellow; ventrals and pectorals white. Iris silvery, orbital margin black. D 8/16, C $17\frac{7}{7}$, A 3/14, V 1/5, P 19, Br. V. Inhabits *Sea of Pinang*, Coromandel, Malabar, Red Sea. Total length: 4 inch. The length of the head is $3\frac{2}{3}$ in the total to the centre of the caudal margin; with the muzzle protracted, it is $3\frac{1}{3}$. The latter projects very slightly downwards, forming a short truncated cone. The lips are rather fleshy and hide the single series of fine setaceous teeth. The diameter of the eye is a little more than $\frac{1}{3}$ of the length of the head. The greatest vertical diameter of the body, in front of the dorsal, is $2\frac{1}{3}$ in the total length. The second dorsal spine is $\frac{1}{5}$ of the total length, a little less than $\frac{1}{2}$ of the greatest vertical diameter; the third dorsal is but little shorter. The second anal spine is $\frac{2}{3}$ of the second dorsal; the third anal slightly shorter than the second. Single individuals occur, but rarely, at Pinang.

(3738) *Equula daura*, Cuvier.

Syn. Russell LXV. Dacer Karah.
Equula daura, Cuvier, R. A. II. 212, (1).
Equula dacer, Cuv. and Val. X. 83.

Young. Head above and back light greenish grey, minutely dotted with black, forming a black line along the base of the dorsal; rest of the body silvery satin; between the occiput and dorsal fin a large triangular blackish spot, not descending to the lateral line; from the posterior angle of the opercle to the caudal a pale yellowish longitudinal band; cheeks and opercles shining silvery, infraorbitals blackish; dorsal hyaline, upper half between the second and sixth spine blackish; caudal yellowish white, minutely dotted with black; anal and pectorals hyaline; ventrals white. Iris silvery, orbital half black. D 8/16, C $17\frac{7}{7}$, A 3/15, V 1/5, P 19, Br. V. Inhabits *Sea of Pinang*, Coromandel, Ceylon. Total length: $2\frac{5}{8}$ inch. The length of the head is $3\frac{1}{4}$ in the total to the centre of the caudal margin; when the conical, slightly downwards arched muzzle is protracted, it is $3\frac{1}{3}$. The diameter of the eye is $\frac{1}{3}$ of the length of the head. The greatest vertical diameter of the body is little less than $\frac{1}{4}$ of the total length. The second dorsal spine is $4\frac{2}{3}$ in the total length; the third is but

little shorter; the second anal is $\frac{1}{4}$ of the second dorsal; the third anal is $\frac{2}{3}$ of the second. Single individuals occur occasionally at Pinang.

(3739) *Equula filigera*, Cuv. and Val.

Syn. Cuvier: Mem. du Mus. I. 402, Pl. 23, Fig. 1.
Equula filigera, Cuv. and Val. X. 92 Pl. 284.
Equula filigera, Swainson II. 250.

Head above and back pale greyish green, minutely dotted with brown; rest of the head and body shining silvery; fins yellowish white; dorsal spines and their membranes, and the muzzle dotted with pale brown. Iris silvery, orbital margin blackish. D 8/16, C 17, A 3/14, V 1/15, P 19, Br. V. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Moluccas, Seychelles, Malabar, Ceylon. Total length: 5 inch. The length of the head is $3\frac{1}{3}$ in the total to the centre of the caudal margin; with the protracted downwards arched muzzle it is $\frac{1}{3}$. The diameter of the eye is $3\frac{1}{3}$ in the length of the head. The fleshy lips entirely cover the narrow bands of setaceous teeth. The greatest vertical diameter, in front of the dorsal fin, slightly exceeds $\frac{1}{4}$ of the total length. The second, slender, flexible dorsal spine is by $\frac{1}{7}$ less than the greatest vertical diameter of the body: the third is about $\frac{1}{3}$ of the length of the second anal; it slightly exceeds $\frac{1}{2}$ of the second dorsal, and is of equal breadth; the third anal is $\frac{2}{3}$ of the second. This species occurs, but not numerously, at all seasons at Pinang.

(3740) *Equula insidiatrix*, (Bloch).

Syn. Zeus insidiator, Bloch, Pl 192, Fig. 2.
Zeus insidiator. Linne, Syst. 1221.
Zee ruse, Lacep. IV. 575.
Zeus insidiator. Shaw IV. 284. Pl. 41.
Equula insidiatrix, Cuv. R. A. II. 212 (2).
Equula insidiatrix. Cuv. and Val. X. 98.
Equula insidiatrix, Bleeker: Verh, Bat. Gen. XXII. 5.

Head above and back metallic violet, paler on the sides towards the lateral line; rest of the head and body shining silvery; head and back minutely dotted with black, forming a blackish line along the base of the dorsal; along the upper part of the sides nine or ten pale reddish brown vertical bands, each consisting of three or four round or irregular spots, descending a little beneath the lateral line; in some individuals a blackish spot on the upper part of the opercle; from the lower part of the orbit along the anterior margin of the cheek an oblique black line bordered behind by a sulphur-coloured one; fins hyaline; caudal minutely dotted, dorsal edged with black; cavity of the mouth minutely dotted with black; internal surface of opercles sulphur-coloured, partially dotted with black. Iris silvery, orbital margin black. D 8/16, C 17, A 3/14, V 1/5., Br. IV ? Inhabits *Sea of Malayan Peninsula and Islands*, Surat, Coromandel, Malabar, Bay of Bengal, mouths of the Ganges, Java, Madura. Total length: $3\frac{3}{8}$ inch. The length of the head is $\frac{1}{4}$ of the total to the centre of the posterior margin of the caudal; when the slightly upwards directed tubular mouth is protracted, it is $\frac{1}{3}$ of the total. The lower margin of the preopercle, particularly the anterior part, is finely yet distinctly toothed. The diameter of the eye is $2\frac{1}{2}$ in the length of the head. The greatest vertical diameter of the body, in front of the dorsal, is a little less than $\frac{1}{3}$ of the total length. The second dorsal spine is $\frac{1}{3}$ of the greatest vertical diameter of the body. The second anal spine is $\frac{2}{3}$ of the second dorsal; the third anal is $\frac{1}{2}$ of the second, but much slenderer. The ventrals are very short, their length somewhat less than the diameter of the eye. The branchiostegous membrane appears to have a fifth excessively minute ray. This species is at all seasons very abundant in the Straits of Malacca, and numbers are dried and consumed by the natives.

(3741) *Equula longimana*, Cantor.

Head above and back lead coloured, minutely dotted with black along the dorsal fin; rest of the head and body shining silvery, slightly iridescent; where the opercle and preopercle join above appears a pale blackish spot; on the anterior part of the side between the commencement of the dorsal and the anterior third of the pectoral, a large rounded bluish black spot; fins hyaline; upper half of dorsal membrane, between the third and eighth spine, indistinctly spotted with pale brown. Iris silvery, orbital half black. D 10/15, C 17, A 4/13, V 1/5, P 13, Br. V. Inhabits *Sea of Malayan Peninsula Islands*. Total length: $4\frac{1}{8}$ inch. The general form of the fish is elongated oblong, the greatest vertical diameter of the body, in front of the dorsal fin, being $\frac{1}{5}$ of the total length, measured to the centre of the posterior margin of the caudal. The length of the head is $3\frac{1}{3}$ in that distance; when the very little downwards protractile mouth is extended, it is $\frac{1}{3}$. The cranial crests are short and less sharp than in the preceding species. No spines appear above the anterior part of the orbit. The diameter of the eye is $2\frac{1}{2}$ in the length of the head. The lips are fleshy, covering a narrow band of minute, recurvous, setaceous teeth, of which there are fewer in the lower than in the upper jaw. The opercle terminates behind in a very obtuse, membranous angle; it is joined to the sub-opercle by an oblique line; by a vertical to the preopercle. The latter the triangular, with the posterior part very thin; the posterior margin is smooth, not toothed, its ascending portion is vertical, the lower rounded, nearly horizontal; the anterior margin is thick, forming a broad, oblique line. The interopercle fits closely so as to cover the branchiostegous membrane; its lower margin is convex. The in-

fraorbitals are completely hid. The cheeks, as well as the rest of the head are covered with scales like those of the body, but the opercles have a scaleless appearance. The indistinct lateral line follows the outline of the back along the upper third of the body. It appears during life to be naked; it is, however, covered with large rounded, diaphanous scales. They are deciduous, and the vertical diameter of the part exposed exceeds three to four times the horizontal. All the spines of the fins are finely transversely striated, but not toothed, and, except the second anal, remarkably slender, transparent. The first dorsal spine is excessively minute; the second is $\frac{1}{3}$ of the third, the length of which slightly exceeds $\frac{1}{4}$ of the greatest vertical diameter of the body; the fourth and fifth are but little shorter. The second anal spine is $\frac{3}{4}$ of the second dorsal, but much broader, sabre-like; the third anal is $\frac{3}{4}$ of the second. The pectorals differ from those of all the other species by being very elongated and falcated; they extend as far back as the posterior third of the dorsal fin; their length is $\frac{1}{3}$ of the total. The ventral are less than $\frac{1}{3}$ of the pectorals. The caudal lobes equal the length of the head. The series of spines along the base of the dorsal and anal fin are very small. In the Straits of Malacca this species is very abundant at all seasons, and quantities, both fresh and dried, are consumed by the natives.

Genus GAZZA, *Ruppell* 1835. Body compressed, with very minute scales; mouth moderate, greatly protractile, with a single series of crooked teeth among which a few longer and stronger than the rest; no teeth on the palatals nor vomer; preopercle with a double margin; the lower part of the external margin serrated; otherwise resembling *Equula*, but the series of spines along the base of the dorsal and anal fins may be felt, not seen.

(3742) *Gazza equulaeformis*, Ruppell.

Syn. Gazza equulaeformis, Ruppell: Neue Wirbelth. Fische, 4, Tab. 1, Fig. 3.

Head above and back pale lead coloured, minutely dotted with black; rest of head and body shining silvery; muzzle and upper lip minutely dotted with black, the cheeks with pale blue; palate, floor of the mouth and internal surface of branchiostegous membrane minutely dotted with black; dorsal and anal spines pale steel blue; fin-membranes hyaline; dorsal between the second and sixth spine minutely dotted with black, superior margin black; posterior half of caudal minutely dotted with black. Iris silvery, orbital margin black. D 8/16, C 17, A 3/14, V 1/5, P 16 or 17, Br. V. Inhabits, *Sea of Pinang, Malayan Peninsula, Singapore*, Massaua (Red Sea). Total length: 4 inch. The length of the head is $3\frac{1}{5}$ in the total to the centre of the posterior margin of the caudal; with the mouth protracted it is $\frac{1}{5}$. The diameter of the eye is $\frac{1}{3}$ of the length of the head. Above the anterior part of the orbit appear two minute spines, and behind them the whole of the upper margin of the orbit is very finely toothed. The greatest vertical diameter of the body, in front of the dorsal fin, slightly exceeds $2\frac{1}{2}$ in the total length. The second dorsal spine is $2\frac{1}{3}$ in the greatest vertical diameter; the second anal is $\frac{3}{4}$ of the length of the second dorsal; third anal is but slightly shorter than the second. The superior branchiostegous ray is closely adhering to the gill-cover; the inferior, (the fifth), is farther removed from the fourth than the other four or among themselves. In the Straits of Malacca this species is very numerous at all seasons, and forms like the rest an article of food.

Genus MENE, *Lacepede* 1803. Mouth like that of *Equula*, but body more compressed; margin of abdomen trenchant, very convex owing to the development of the scapular and pelvic bones, throwing the ventrals farther back than the pectorals; profile of the back nearly horizontal.

(3743) *Mene maculata*, (Bloch-Schneider).

Mene maculata, Temm. Schl. Fauna Japon. Pisc. 127, Pl. LXVII. Fig. 3.
Mene maculata, Richardson, Report 1845 276.

Head above and back greenish lead coloured, paler on the sides towards the lateral line; rest of the body silvery satin; above the lateral line one or two longitudinal series of more or less distinct, rounded, lead coloured spots; beneath the lateral line two similar series; jaws, cheeks and opercles shining silvery; dorsal pale olive greyish, minutely dotted with black; caudal silvery at the base, rest yellowish white, minutely dotted with black; anal silvery white; ventrals white, first, elongated ray, silvery at the base, rest blackish; pectorals hyaline; lips blackish; tongue, and internal surface of the mouth dotted with black. Iris silvery, orbital margin blackish. D 4/43, C $17\frac{1}{2}$, A 31, V 1/5, P 16, Br. VII. Inhabits, *Sea of Pinang*, Java, Coromandel, Japan. Total length: 5 inch. The length of the head is $3\frac{1}{3}$ in the total to the centre of the posterior margin of the caudal with the muzzle protracted it is $2\frac{3}{4}$. The diameter of the eye is $3\frac{1}{2}$ in the length of the head. The teeth are excessively minute, velvety: in the upper jaw their narrow linear band suddenly widens towards the angle of the mouth. In the space between the interparietal and the interspinal crest, front of the dorsal fin, appear in succession three small flat-

tened, lancet-shaped ossicles. The greatest vertical diameter of the body, in front of the dorsal fin, is a little less than ⅓ of the total length. In a solitary individual, observed in August 1845 at Pinang, the lateral line presents the following appearance, The short anterior part, consisting of three rather large tubes, rises nearly vertically, when it turns backwards under a nearly right angle, and proceeds very close to the back towards the origin of the dorsal, where it suddenly disappears. A similar line, but formed of much smaller tubes, commences on the upper fifth of the back, opposite the eighth dorsal ray, and proceeds, deviating a little obliquely upwards. to the thirty-first dorsal ray, where it suddenly terminates. The length of the first ventral ray is 2½ in the total length. The pectoral rays are remarkably broad, compressed, particularly the second which resembles the blade of a sabre.

Fam. CHÆTODONTIDÆ.

Gen. CHÆTODON, (*Artedi*) *Linne* 1748. Teeth of the jaws slender, flexible and close like the hairs of a brush; mouth very small, slightly or not at all projecting; body elliptical or nearly orbicular; caudal fin truncated; 12 or 13 dorsal, 3 anal spines; dorsal spines and rays continued in a nearly uniform curve; branchiostegous rays six.

(3744) *Chætodon prætextatus*, Cantor.

Plate III.

Head as far as the occiput, gill-covers and throat black; on the chin a rounded white spot; a white band round the throat to the angle of the mouth; a second, also encircling the throat, obliquely upwards and forwards in front of the eye across the forehead; a third, narrow, backwards arched white line on the forehead between the eyes; a broad white band surrounding the chest, narrowing as it vertically ascends between the preopercle and the eye, and continues to a little in front of the first dorsal spine; body and the scaly part of the dorsal and anal fin lightly greyish brown; each scale minutely dotted with black, and on the body with a short central dark bar, reflecting a series of parallel lines ascending obliquely backwards; dorsal spines vermilion, their membrane light greyish brown; margin of the soft fin black (the very point of the rays colourless,) beneath bordered by a narrow white line, under which a broad vermilion band, gradually widening backwards; in some the latter is placed immediately under the black margin, and longitudinally divided by a narrow white line; on the anterior half of the caudal a vertical vermilion band, next a narrower black, behind which the rest of the fin is white; anal spines light brownish grey, membrane black; margin of the soft part black (the very point of the rays colourless,) bordered above by a broad crescent shaped vermilion band; ventrals black; pectorals brownish or blackish at the root; the rays brownish white, membrane transparent. Iris milky white or buff. D 12/26, 27 or 28, C 17½ A 3/20, 21 or 22, V 1/5, P 15 or 16, Br. VI. Inhabits *Sea of Pinang*. Total length 5⅛ inch. The outline of the much compressed body is broad oval, deeply emarginated behind by the three vertical fins; the profile descends nearly straight from the dorsal fin to the narrow, slightly elongated muzzle. The greatest vertical diameter of the body, taken from the root of the 7th dorsal spine, is ½ of the total length. The length of the head, nearly equalling the height at the occiput, is about ¼ of the total length; the eye is situated a little above the centre of the longitudinal diameter, but in the centre of the greatest vertical diameter of the head; its diameter is ⅓ of the length of the head. The mouth is slightly protractile, very small, the cleft being ⅓ of the length of the head; the teeth are normal; the nostrils open near the anterior part of the orbit; the preopercle is narrow; near the angle are a few indistinct crenulations: the operacle terminates in a small flat membranous point. The black ocular band is in front bordered by the second white band, which obliquely encircles that part of the head; behind by the posterior white band; which from the chest proceeds vertically over the preopercle to a little in front of the anterior dorsal spine. As the profile of the head is sloping, the black ocular band is nearly threesided, much broader above than below the eye. The dorsal spines gradually increase in length till the fifth which, as well as the rest, is nearly equal ⅔ of the length of the head; the two anterior spines are exposed; the rest become gradually covered with scales which spread in an oblique arched line, so as barely to leave the points of the three last spines visible; the soft portion is gently arched, scaly, highest in the middle, where the rays slightly exceed the length of the fifth spine. The length of the caudal fin is a little more than ½ of the length of head; the posterior margin is straight when at rest, but rounded when expanded, and then more than double the length of the fin; the anterior ¾ are covered with scales. The anal commences opposite the 8th or 9th dorsal ray; the anterior spine is ⅓ of the second and third, which in length equal the fifth dorsal; they are gradually covered with scales, so that of the last one third only is exposed; the soft part is rounded, scaly, its highest elevation in the middle equalling that of the dorsal. The ventrals commence opposite the termination of the root of the pectoral; the length of the spine is ½ that of the head, and ⅔ of that of the first ray; above the root of each ventral appears a broad pointed scale. The length of the pectorals is a little more than ⅕ of the total. The scales of the body are rounded, higher than long, ciliated; those of the lateral line much smaller than the rest and nearly triangular; the line itself ascends

backwards till opposite the 11th dorsal spine, from whence it descends, closely following the back to the termination of the soft dorsal fin. The lateral line follows a similar course in *Chætodon reticulatus*, Cuv. and Val. Of the present species two were observed at Pinang in May 1845, and in June, eleven were taken together in a fishing net, all nearly of equal size. The fishermen asserted the fish to be an excellent article of food, but of rare occurrence, and not to attain greater dimensions. Like other species of this and the neighbouring genera, the present expires immediately, when removed from its element. It appears to be allied to *C. reticulatus* and *C. lunula*, Cuv. and Val.

Genus CHELMON, *Cuvier* 1817. Muzzle excessively long, slender formed by the horizontally elongated internaxillary bone and the lower jaw, both of which have one half or two thirds united by a membrane, so as to reduce the mouth to a small horizontal cleft at the extremity of the cylinder; teeth in both jaws fine, velvety; in other respects like *Chætodon*.

(3745) *Chelmon Rostratus*, (Linne.)

Syn. Seba. III. Pl. 25 Fig. 17.
Chætodon rostratus, Lin. Mus. Ad. Fr. I. 61, Tab. 33, Fig. 2.

Chætodon enceladus, Shaw: Nat. Misc. 2, Pl. 67.
Chætodon rostratus Shaw: IV. 337, Pl. 47.
Chelmon rostratus. Cuv. R. A. II. 190.
Chelmon rostratus, Bennett: Life of Raffles, 689.
Chelmon rostratus. Cuv. and Val. VII. 87.

Ground colour of body and fins silvery, with one frontal and five vertical, lateral bands; all, except the fifth, orange or brownish ochreous, edged with blackish brown, outside of which with white; the frontal band along the profile of the head to the point of the elongated muzzle; the first lateral from the occiput through the iris to the throat; the second from between the first and second dorsal spine over the opercle in front of the pectoral to the abdomen in front of the ventrals; the third from the sixth and seventh dorsal spine down to the anus; the fourth, the broadest from between the ninth spine and the tenth dorsal ray to between the third anal; within this band, at the base of the soft dorsal, a rounded black spot edged with white; the fifth, in front of the caudal, black with white margins. The soft dorsal and anal with a black margin, the base of which bordered by a white line enclosed between two black ones; the anterior half of the caudal pale ochreous, the rest as well as the pectorals and ventrals white, the latter minutely dotted with black. Iris pale golden orange, longitudinally divided by the ocular band. D 9/29, C 17/$\frac{1}{3}$, A 3/20, V 1/5, P 10, Br. V. Inhabits *Sea of Singapore, Malacca*, Sea and rivers of Java, Sumatra. Total length: 5$\frac{1}{8}$ inch. Numbers were observed in May 1840, at Singapore; they were, however, all dead, and their colours apparently somewhat faded. The fish is considered excellent by the natives, and eaten both fresh and dried. At Malacca it appears to be of rare occurrence, and at Pinang no specimen was observed during upwards of four years search. The fishermen, judging from a drawing, asserted that they were acquainted with the species, but they invariably brought *Platax ocellatus*, Cuv. and Val. instead, which in colours and their peculiar distribution, certainly offers a remarkable resemblance to the present species.

Genus DIPHREUTES, *Cantor*. [Διφρευτης, a charioteer. Substituted for *Heniochus*, Cuvier 1817, pre-occupied by *Henioche*, Hubner 1816. (*Lepidoptera.*)] (*Equivalent to* Heniochus, *Cuvier.*) The anterior dorsal spines rapidly increasing in length, the third or fourth filamentous, sometimes double the length of the body, resembling a coach-whip; scales large.

(3746) *Diphreutes macrolepidotus*, (Linne.)

Syn. Chætodon macrolepidotus, Linne, Syst.
Chætodon macrolepidotus, Bloch, Pl. 200, Fig. 1.
Chætodon bifasciatus, Shaw IV. 342.

Heniochus macrolepidotus, Cuv. and Val. VII. 93, Pl. 176.
Heniochus macrolepidotus, Temm. and Schl. F. J. Pise. 82, Tab. XLIV. Fig. 1. (*Young.*)
Heniochus macroclepidotus, Richardson, Report 1845, 246.

Young. Ground colour of the head and body milk-white; on the upper part of the muzzle, as far as the anterior opening of the nostrils, a small black rectangular band; between the eyes across the forehead, a backwards pointing angular black band; a broader, comprising the three anterior and in some the root of the elongated fourth dorsal spine, proceeds obliquely downwards over the side and posterior part of the opercle, from whence it becomes broader, spreading in front over the ventrals, behind over the spinous part of the anal, edging, the soft part; a posterior black band, partially covering the 5th, 6th, 7th and 8th dorsal spine, proceeds obliquely backwards over the side covering the posterior half of the soft anal. The fourth elongated, flexible, dorsal spine and its membrane milk-white, minutely dotted with black; rest of the dorsal, the caudal and pectoral fins bright gamboge or citrine. Iris gamboge, blackish towards the orbit, divided by an oblique

black band, appearing as a continuation of the angular one of the forehead. D 11/25 or 26, C 17⅔, A 3/18 or 19, V 1/5 P 17, Br. V. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula,* Manilla, Moluccas, New Guinea, Celebes, Ceylon, Pondicherry, Isle of France, Mauritius, Mozambique, Japan. Total length; 6 inch. Solitary young individuals, not exceeding the length given, occur at all seasons at Pinang.

Genus ILARCHES, *Cantor.* [Ιλαρχης, commander of a troop. Substituted for *Ephippus*, Cuvier 1829, pre-occupied by *Ephippium*, Latreille 1802 (*Diptera.*)] (*Equivalent to* Ephippus, *Cuvier.*) Body oval or nearly orbicular: dorsal fins two, or one deeply emarginated between the spinous and soft portion; the former not covered with scales, capable of reclining in a groove, formed by the skin of the back; anal spines three; pectorals oval.

(3747) *Ilarches orbis*, (Bloch.)

Syn. Chætodon orbis, Bloch, Tab. 202, Fig. 2.
Chætodon orbis, Linne, Syst. 1244.
Chætodon orbe, Lacep. IV. 458, 491.

Ephippus orbis, Cuvier and Val. VII. 127.
Ephippus orbis, Swainson, II. 213.
Ephippus orbis, Richardson Rep. 1845, 245.

Head above and back light greyish green; sides and abdomen silvery with pale lilac lustre; fin-membranes transparent, minutely dotted with black, giving the marginal half a blackish appearance; dorsal and anal spines and their membranes, pale silvery, the rays yellowish white. Iris pale golden, minutely dotted with black. D 8—1/19, C 17⅞, A 3/16, V 1/5, P 19, Br. VI. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula,* Malabar, Tranquebar, Pondicherry, Indian and China Seas. Total length: 5⅛ inch. The greatest vertical diameter of the head exceeds by ⅓ its length, which is a little less than ¼ of the total; the greatest vertical diameter of the body is 1¾ in the total length. The young individuals, like those of *Ilarches fuber*, (Brouss). are of a less orbicular outline than the adult, their greatest vertical diameter being ½ of the total length. On each side of the centre of the upper jaw appears a small pore, and on each side of the symphysis of the lower two similar, the one placed a little in front of the other. There is besides a large pore or sometimes two on each branch of the lower jaw. The posterior margin of the caudal fin is not straight, but convex in the centre, above and below which it is slightly concave. In the young the color of the dorsal membrane, particularly the upper half of the soft, the anal and the ventral is of a deeper black than in the adult. Although individuals occur at Pinang at all seasons, they are not numerous. The fish though bony, and considered indifferent, is by the natives consumed both fresh and dried.

Genus HARPOCHIRUS, *Cantor,* [Αρπη, scythe χειρ, hand. Substituted for *Drepane*, Cuv. and Val. 1831, pre-occupied by *Drepana*, Schrank 1802 (*Lepidoptera*).] (*Equivalent to* Drepane, *Cuv. and Val.*) Pectoral fins elongated, falciform, nearly reaching the base of the caudal; outline of the body almost quadrangular.

(3748) *Harpochirus punctatus*, (Linne).

Syn. Chætodon punctatus, Linne: Syst. 1243.
Chetodon faucheur, Lacepede.
Chætodon punctatus, Shaw, IV. 365.
Russell LXXIX. Latte.
Ephippus punctatus, Cuv. R. A. II. 191 (4).

Drepane punctata, Swainson II. 213.
Drepane punctata, Richardson, Report 1845, 245.
Drepane punctata, Bleeker: Verh. Bat. Gen. XXII. 5.

Head and body iridescent silvery; the crest from the occiput to the dorsal fin blackish; the upper half of the sides with more or less regular vertical series of small black spots; in some a small black spot in the axilla, in others a single oblique series of spots at the base of the soft dorsal; spines and rays pale silvery, the anterior margins of the first dorsal ray black; fin-membranes whitish transparent, the scaly portion silvery, the marginal minutely dotted with black, in some sufficiently strong to impart a blackish appearance to the marginal half. Iris silvery. D 8—1/20 or 21, C 17⅜, A 3/17, V 1/5, P 17 or 18, Br. VI. Inhabits *Sea and estuaries Pinang, Malayan Peninsula, Singapore,* Coasts of New Holland, New Guinea, Southern coasts of China, Java, Celebes, Madura, Bay of Bengal, Gangetic estuaries, Malabar. Total length: 1 foot 5 inch. The body appears to become elongated with age; in the adult the diameter from the angle of the back to that at the commencement of the anal fin is about ⅚ of the length of the body, the caudal not included. In the young it is something more than ⅘ of that distance. In the very young individuals the occipital crest is denticulated, and they are at all seasons numerous at Pinang, but large individuals occur rarely. In the largest observed, the length of which is given above, the rounded protuberance of the skull between the eyes is very large and prominent, and the roots of the four central caudal rays are enlarged and joined together without any intermediate membrane. A similar enlargement of the occipital crest and some of the bones occurs in adult individuals of *Platax arthriticus*, Cuv. and Val. The present species is bony and insipid. It is, however, eaten by the natives in its fresh and dried state.

(3749) *Harpochirus longimanus*, (Bloch-Schneider.)

Syn. Chætodon longimanus, Bloch-Schneider, 231.
Russell LXXX. Terla A.
Russell LXXXI. Terla B.
Ephippus longimanus, Cuv. R. A. II. 191 (3).
Drepane longimana. Cuv. and Val: VII. 133.
Drepane longimana, Richardson Report 1845.

Young. Head and body iridescent silvery; the crest from the occiput to the dorsal fin blackish; the upper half of the sides with four or five vertical, more or less distinct, lead coloured bands. Fins like *H. punctatus*. Iris silvery. *Adult.* Body uniformly iridescent silvery; rest like the young. Number of fin rays like *H. punctatus*. Inhabits *Sea and estuaries of Pinang, Malayan Peninsula, Singapore,* Java, Bay of Bengal, Gangetic estuaries, Malabar, China Seas. Total length: 8⅛ inch. Except the colours, no external character can be assigned to distinguish the two species; but anatomical differences have been pointed out by M.M. Cuvier and Valenciennes. Large individuals are rarely seen at Pinang, but there, as in the mouth of the Ganges, young ones are very numerous. During life or shortly after death, none of those examined presented the red colour described by Russell.

Genus CACODOXUS, *Cantor.* [Κἀκοδοξος, ill-reputed. Substituted for *Scatophagus*, Cuv. and Val. 1831, pre-occupied by *Scatophaga*, Meigen 1802. (*Diptera.*)] (*Equivalent to* Scatophagus, *Cuvier and Valenciennes.*) Four anal, eleven dorsal spines; scales excessively small.

(3750) *Cacodoxus argus*, (Linne.)

Scatophagus areus, Cuv. and Val. VII. 136.
Scatophagus argus, Richardson Report 1845. 245.
Scatophagus argus, Bleeker: Verh. Bat. Gen. XXII. 5.

Head above and back silvery blackish or brownish green, or purple, lighter on the sides; abdomen whitish or yellowish; back and sides, and in some the opercles, with blackish or brownish spots, in form, number and size liable to individual variations; dorsal and anal spines and membranes silvery, minutely dotted with black, imparting to the latter a more or less intense colour; dorsal, caudal and anal ray of the ground colour of the body, their membranes more or less intense black, with or without some smaller spots like those of the body; ventrals greyish or whitish, minutely dotted with black; pectorals whitish. Iris brown or blackish with a narrow golden circle round the pupil. D 10 –1/18, C 17½, A 4/14, V 1/5, P 18. Br. VI. Inhabits *Estuaries and Sea of Pinang, Malayan Peninsula, Singapore,* Malabar, Ceylon, Bay of Bengal, Gangetic estuaries, Java, Celebes, Madura, Moluccas, China Sea. Total length: 10 inch. The young are generally of more brilliant colours; in one taken in the Joomrah, one of the mouths of the Ganges, the dorsal spines and ventral fins were of a deep red. At Pinang this species is not very numerous. It is eaten by the natives, though many reject it on account of its reputed disgusting habits. In several examined in the estuaries of the Ganges, and at Pinang, the stomach contained remains of small fishes and crustacea. According to Bennett, it is in Ceylon angled on hooks baited with a kind of sea-weed ("Pendah,") of which this fish appears to be particularly fond.

Genus HOLACANTHUS, *Lacepede* 1802. With a large backwards pointed spine at the angle of the preopercle, the margins of which are toothed.

(3751) *Holacanthus annularis*, (Bloch.)

Syn. Chætodon annularis, Bloch. Tab. 214.
Chætodon annularis, Linne: Syst. 1262.
Holacanthe anneau, Lacepede IV, 526, 533.
Chætodon annularis, Shaw, IV. 330, Pl. 47.
Russell, LXXXVIII. Sahni Tchapa.
Holacanthus annularis, Cuv. R. A II. 122 (4).
Holacanthus annularis, Cuv. and Val.

Ground colour of the body and fins light brown with golden lustre, darker on the head; external half of soft dorsal and anal blackish; scales of the body with a central blackish spot; at a little distance above the shoulder and opercle a ring of deep blue, internally and externally edged with black; on the body a number of similarly coloured oblique, slightly arched bands: the anterior, from the 7th dorsal spine, obliquely downwards, terminating a little below the ring; the second from the 10th dorsal spine; the third from the 4th dorsal ray joins the termination of the two preceding bands; the succeeding radiate from about the fifth dorsal, each describing a larger arch, the fourth terminating opposite the point of the opercle; the fifth in the axilla, the sixth, seventh and eighth, which latter passes along the base of the anal, terminate between the root of the pectoral and ventral; the ninth passes vertically in front of the caudal fin, spanning the soft anal; the tenth and eleventh follow the course the ninth. From the orbit a short horizontal blue black edged band, which on the opercle divides in three branches, of which the lower

passes obliquely down to meet the fourth of the body; from the nostrils to the upper part of the preopercle another horizontal band. Dorsal and anal spines white, covered by the brownish membrane; caudal, ventral and pectoral rays, light yellowish brown, membrane dark brown; the large preopercular spine white, the shallow groove on the external surface filled with a brown membrane; to the slightly convex upper margin is attached a black, loose membrane. Iris brownish golden, the orbital half speckled with black. D 13/22, C 17, A 3/21, V 1/5, P. 18, Br. VI. Inhabits *Sea of Pinang*, Moluccas, Malacca, Pondicherry, Vizagapatam. Total length: 1 foot. In November 1843 a single individual was observed at Pinang. From the descriptions and figures published, it appears that the number and distribution of the bands are liable to individual variations. In the one examined, the length of the entire fourth dorsal ray did not exceed that of the first ventral, whereas it commonly projects beyond the caudal fin. The figure of Russell is defective in not representing the loose membrane attached to the superior concave margin of the large spine, nor the dentitions of the margins of the preopercle.

Genus PLATAX, *Cuvier* 1817. Teeth setaceous, external series trilobate; body very compressed and high; dorsal spines few, hid in the anterior margin of the fin; anterior rays of dorsal, anal and ventral fins elongated, in some falciform.

(3752) *Platax Vespertilio*, (Bloch).

Head and body pale bluish silvery brown, lighter on the cheeks, opercles, throat, sides and abdomen; the scales minutely dotted and edged with blackish brown, and sometimes with a few scattered small dark spots on the sides; the ocular, pectoral and caudal band indistinct; basal half of dorsal and anal fins like the body; upper half blackish; the rays whitish; caudal pale greyish transparent; posterior margin blackish; ventrals blackish; pectoral rays brownish yellow, with a broad brownish band at the base. Iris brownish golden, vertically divided by the ocular band. D 5/36, 37, 38 or 39, C. 17½, A 3/25, 26, 27 or 28, V 1/5, P 17 or 18, Br. VI, Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Isle of France, Red Sea, Ceylon, Bay of Bengal, China Sea, Japan, New Guinea, Amboina, Java, Madura. Total length: 7 inch. The greatest height of the body is a little less than ¾ of the total length or equal the distance from the symphysis of the lower jaw to the termenation of the dorsal and anal fins. [In the present and in the two succeeding species, it is calculated from the first dorsal to the first anal spine].

Platax guttulatus, Cuv. and Val. VII. 227 Pl. 186.
Platax vespertilio. Rüppell: Neue Wirbelth. Fische. 33.

Head and body pale silvery chocolate coloured; cheeks, opercle, throat and abdomen bluish white; on the forehead above each orbit a brown dot; from the occiput through the iris to the ventrals, a continued or interrupted dark brown band, or light brown with dark edges; from the first dorsal spine to the pectoral more or less distinct traces of a second band; on different parts

of the body some scattered pearl-coloured spots, with dark brown edges and of irregular shape; base of dorsal and anal of the ground colour of the body; rest of their membranes bluish white dotted with black; their margins blackish; rays light greyish; base of the caudal of the ground-colour of the body with a vertical, forwards arched, dark brown band; rest of the fin pale yellow; ventrals blackish; the fifth ray and its membrane whitish, minutely dotted with brown; pectorals yellowish white. Iris pale chocolate coloured, with a narrow golden ring, vertically intersected by the ocular band. Total length: 1⅛ to 3⅛ inch. In individuals of the given dimensions, the greatest height equals the length of the body to the centre of the dark band on the caudal fin, or it is about ⅛ less than the total. The elongation of the anterior dorsal, anal and ventral rays is liable to individual variations, the maximum of the two former fins not exceeding ¾ of the greatest height of the body. The ventrals never exceed ⅔ of the greatest height. On each side of the lower jaw appear three minute distant pores. In the early age the teeth of the two or three external series are trilobate, but they become blunter with age. At Pinang young individuals with pearl-coloured spots, appear to be of rarer occurrence than the others. The intestinal canal is nearly twice the length of the fish; of the five cæcopyloric appendages the three larger are of nearly equal length; the other two are very minute; the air-vessel is lanceolate, very thin, pearl coloured. In individuals of all ages the stomach contained remains of fishes and crustacea. Dr. Ruppell adds *Platax gaymardi*, Cuv. and Val. (VII. 216) to the synonymes of the present species.

(3753) *Platax teira*, (Forskal).

Syn. Chætodon pinnatus, Chinens. Lagerstr No. 25?
Chætodon teira, Forskal, 60 No. 82, Tab. XXII.
Chætodon teira, Bloch, Tab. 199 Fig. 1.
Chætodon teira, Linné Syst. 1265.
Chætodon teira, Shaw, IV. 345, Pl. 48.
Platax teira, Cuv. R. A. II. 193 (1)
Platax teira, Ruppell: Atl. 68.
Platax teira, Cuv. and Val. 226.
Platax teira, Ruppell: Neue Wirbelth. Fische 33. 37.

Young. Ground colour of the body, dorsal, anal and ventral fins pale silvery whitish, the scales edged with blackish brown or deep purple; opercles, throat and abdomen bluish white, minutely dotted with black; from the occiput, through the iris over the ventral soft fin a blackish band; a second from the anterior margin of the dorsal fin, spreading over the dorsal spines, continuing vertically over the posterior part of the opercle to the abdomen; a third over the posterior part of the dorsal, the body and the anal fin and over the base of the caudal; the rest of the caudal and the pectorals whitish. Iris pale golden, vertically divided by the ocular band. *Older.* The vertical bands very indistinct; dorsal, anal and ventral fins bluish black or brown; caudal greyish brown, the margin blackish. Iris blackish or brownish with a narrow golden ring round the pupil. D 5/31 or 32, C 17½, A 3/23, 24 or 25, V 1/5, P 17, Br. VI. Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Singapore*, Red Sea, Malabar, Bay of Bengal. Total length: 8 inch. The greatest height equals the length of the body, the caudal fin not included; the latter, as also the head, being ¼ of the total length. The elongation of the anterior rays of the dorsal, anal and ventral fins is comparatively greater in young than in older individuals; in all, however, it is liable to considerable individual variations. The dorsal and anal are either equal or differing: in the young their greatest elongation exceeds by ⅓ the greatest height of the body. The ventrals often differ among themselves: in the young their greatest length does not exceed the greatest height of the body, in older ones it slightly exceeds one half of that distance. On each side of the lower jaw appears three small distant pores. At Pinang smaller individuals occur at all seasons; larger ones are less frequent.

(3754) *Platax arthriticus*, Cuv. and Val.

Syn. Ecan bonna, Bell: Philosoph. Transact. 1793.
Chætodon arthriticus, Cuv. and Val. VII. 229.

Head, back, sides, dorsal, caudal and anal fins dull chocolate brown or lead coloured, in some largely marbled with dark brown; abdomen pale whitish; ventrals brownish yellow; pectoral whitish. Iris of the ground colour of the body, with a narrow golden ring. D (5)/31, C 17½, A (3)/23, V 1/5, P 17, Br. VI. Inhabits *Sea of Pinang*, *Singapore*, Java, Sumatra. Total length: 1 foot 7 inch. The dorsal and anal spines are so completely hidden, that they are imperceptible to the touch, but on close inspection their points may be perceived through the integuments. The greatest height equals the distance from the muzzle to the termination of the dorsal and ventral fins. The diameter of the eye is ¼ of the length of the head, which is about ¼ of the total. The large arched occipital crest, and the nodulous enlargement of some of the bones render this species easily distinguishable. On each side of the symphysis of the upper jaw appears a minute pore, and five somewhat larger on each side of the lower jaw. At Pinang this species is not numerous, although from October till January eight or ten are sometimes captured at a time in the fishing stakes. The flavour is considered excellent. The large air-vessel is too thin, and yields too little isinglass to become of value.

(3755) *Platax ocellatus*, Cuv. and Val.

Syn. Platax ocellatus, Cuv. and Val. VII. 229.

Ground colour of body and fins pale ochreous silvery; with one frontal and five lateral ferruginous bands, edged with black: a narrow frontal band along the profile of the head to the point of the muzzle; the first lateral from the occiput, describing a forwards directed arch, through the iris, over the cheek to a little in front of the ventrals; the second, less arched, from in front of the dorsal, bordering on the opercle, enclosing the base of the pectoral to midway between the ventrals and anus; the third following obliquely the two or three posterior dorsal spines, proceeds a little backwards down the side, to the anterior margin of the anal; the fourth, the broadest, from between the spine and soft part of the dorsal, describing a slightly backwards directed arch down the side and over the anterior third of the anal; at the base of the dorsal within this band a large rounded or oval black spot; the fifth band follows the margin of the soft dorsal; in front of the caudal, within the black edges of this band, a vertical oval black spot with a broad white margin; the rest of the band following the margin of the soft anal, successively joins the fourth and third preceding bands; the dorsal spines and the angle they form with the rays of a brilliant orange, which spreads over the origin of the fourth and fifth bands. Anterior half of caudal ferruginous, posterior whitish, bluish or blackish towards the margin; pectorals yellowish white; ventrals milky white, the marginal half of the soft part black. Iris pale golden, vertically divided by the anterior lateral band. C 6 or 7/29 or 30, C 17½ A 3/19 or 20, V 1/5, P 15, Br. VI. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore.* Total length: 3⅝ inch. The length of the head is a little less than ¼ of the total, its greatest vertical diameter slightly exceeding the length. The eye is situated a little above the centre of the vertical diameter of the head, close to the profile; the diameter is a little less than ⅓ of the length of the head, equal the distance across the forehead. The form of the body is broad oval, the back and abdomen forming uniform arches, interrupted by the somewhat horizontally protracted muzzle. The greatest height of the body, from the root of the fourth dorsal ray to the first anal spine, exceeds by ⅓ half the total length. The mouth is very small, slightly protractile, the lower jaw longer than the upper; the teeth setaceous, all uniformly pointed, none trilobate. The anterior dorsal spines are very short, the rest gradually increase, the last equalling the length of the head. The two or three anterior rays, the longest, slightly exceed ⅓ of the greatest height of the body; the extent of the base of the dorsal fin equals the length of the body, the head and caudal not included. The posterior margin of the caudal is slightly arched; the length of this and the pectoral fins is about ⅓ of the total. The third anal spine equals the fifth dorsal; the two anterior rays, the longest, measure ⅓ of the longest dorsal rays; the extent of the base of the anal is less than ⅔ of that of the dorsal. The ventral spine equals the fifth dorsal spine; the first ray is elongated, about the length of the head. The scales are rather large, orbicular, finely ciliated; the lateral line continues straight to a short distance from the head, where it rises to a moderate arch, gradually approaching the back till suddenly terminating beneath the last dorsal rays. The proportions and the colours are the same in all ages. The uniformly setaceous teeth, the comparatively less height of the body and elongation of the dorsal and anal fins are characters which remove this species from the rest, and approach it to the Genus *Chætodon*. As above observed, the peculiar distribution of colours bears a striking resemblance to that of *Chelmon rostratus*. (Linne). During the month of May 1840 numerous individuals were daily observed in the fishmarket at Singapore. At Pinang single individuals occur during all seasons. The fish is eaten both fresh and dried by the natives, although reputed indifferent and bony.

Genus MONODACTYLUS. *Lacepede.* 1800. Body compressed; dorsal and anal scaly, more or less falciform, with their spines hid to the point in the anterior margin; teeth close, velvety, ventral spines minute, the latter so as easily to escape observation.

(3756) *Monodactylus rhombeus* (Forskal.)

Syn. Scomber rhombeus, Forskal Fauna Arab. 58, No. 78.
Centrogaster rhombeus, Linne: Syst. 1338.
Centropodus rhomboidalis, Lacepede III 303, 304, 305.
Russell, LIX. Kauki Sandawa.
Psettus rhombeus, Cuv. R. A. II. 193
Psettus rhombeus, Cuv. and Val- VII. 245.
Monodactylus rhombeus, Swainson II. 212.

Adult. Profile of the head and back black: the rest above the lateral line golden green: sides of the head, opercles, and the body beneath the lateral line pale silvery; from the anus to the anal fin a black line; from the occiput to the centre of the upper margin of the orbit an oblique black band, continued through the pale golden iris, and in some over the cheek; a second similar band from the first dorsal spine to the point of the opercle; anterior margin of dorsal and angle formed by the anterior six or eight rays black; the branched part of the succeeding rays gamboge, minutely dotted with black; the rest of the fin golden green; caudal gamboge, margin black or blackish; anterior margin of anal and the angle formed by the anterior four rays

bluish black; the branched part of the succeeding rays pale bluish or blackish, minutely dotted with black: the rest of the fin greenish or bluish silvery; anal spines and rays white, the latter minutely dotted with black; pectorals yellowish white. *Young*. Like the adult, but the head, body, dorsal and anal fins, minutely dotted with black, in some so closely, as to impart a general blackish colour. D 8/28, 29 or 30, C 17⅔, A 3/29 or 30, V 1/3, 4 or 5, P 17 or 18, Br. VI. Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Singapore*, Isle of France, Red Sea, Coromandel. Total length: 5⅛ inch. The length of the head is contained 3½ times in the total; its greatest vertical diameter is ⅓ of the total length. The diameter of the eye is contained 2½ times in the length of the head, but equals the distance across the forehead. The height of the body, between the origin of the dorsal and anal fins, is contained about 1½ time in the total length: it equals the distance from the centre of the anterior part of the orbit to the termination of the dorsal and anal fins. Vertically measured, the dorsal equals the length of the head; the anal is somewhat more; it nearly equals the greatest vertical diameter of the head or about ⅓ of the total length. The ventral spines are very short, but strong, each being $\frac{1}{10}$ of the length of the head; at the base both are almost in contact, but their points diverge. The ventral rays of each fin are contained in a small grove in the body; they are very minute and their number not only varies from 5 to 3 in different individuals, but also on either side in the same individual. The proposed genus *Psettus*, Cuv. and Val. 1831, is characterised as having no palatal teeth, which, as far as the present species is concerned, is a mistake. Forskal's diagnosis of *Scomber rhombeus*: "*dentes numerosi subtiles. Lingua obtusa, prope apicem superne callo ovali, plano, albido scabro*," which is perfectly correct. All the teeth are velvety, "en velours ras et serre;" those of both jaws appear like narrow bands; of the vomer like a small rhombic elevation; of the plate on each side like a lancet-shaped line, broader in front; of each of the pterygoid bones like a triangular band, broader than the rest, and with the apex in front. On the oval tongue the teeth occupy the middle, leaving the margin naked. Single individuals occur during all seasons at Pinang, where they are eaten by the natives.

Genus **PIMELEPTERUS**, *Lacepede* 1802. Body oval, compressed; dorsal single, its rays, as well as those of the caudal and anal, covered with scales; the single external series of maxillary teeth trenchant, fixed by means of a horizontal posterior process resembling a talon.

(3757) *Pimelepterus oblongior*, Cuv. and Val.

Syn. Pimelepterus oblongior, Cuv. and Val. VII. 264.

Adult? Head above and back blackish brown; the scales silvery brownish grey, edged with brown: those above the lateral line with darker brown than those below; each series of scales longitudinally separated from the succeeding by a lighter or darker ferruginous stripe, imparting to the body a striped appearance; from beneath the eye, over the cheek and opercle a ferruginous stripe; a second continued or interrupted, from behind the orbit to the point of the opercle; on the occiput some irregular ferruginous spot. Dorsal and anal spines and membrane pale greyish brown, or neutral tint, minutely dotted with brown; soft portion of dorsal, anal and the caudal of the ground colour; their marginal part blackish; ventrals pale bluish grey, minutely dotted with brown, marginal half blackish; pectoral rays buff, membrane transparent; the scales of the base and those between the rays like those of the body. Iris silvery near the pupil, the rest bluish black or brown. *Young*. Ground colour of the body paler and with a bluish tint; lateral stripes paler and fewer. D 11/12, 14 or 15, C 17⅔, A 3/12, 13 or 14, V 1/5. P 18 or 19, Br. VII. Inhabits *Sea of Pinang*, *Malayan Peninsula*. Total length: 7⅝ inch. The length of the head is contained less than four times in the total: its height at the occiput equals the length. The eye is situated above the centre of the head, nearer the muzzle than the gill-opening: its horizontal diameter is about ⅓ of the length of the head. The greatest vertical diameter of the body slightly exceeds ⅓ of the total length. The number of external maxillary teeth appears to increase with age: the largest individual examined had 30 in each jaw. Their size decreases from the centre towards the angles of the mouth; the posterior, horizontal process is slightly longer than the anterior trenchant one. Behind the external series is a narrow crescent-shaped naked space, from the posterior concave margin of which rises a single series of minute, distant, backwards arched teeth. On the vomer appears a transversely oval elevation with velvety teeth; on each palatal bone a narrow line, and on each pterygoid a broad lanceolate elevation with similar teeth. The tongue is small, but broad, rounded in front; on each side of the base appears a small oval spot of velvety teeth. The largest individual presented nine longitudinal series of scales above the lateral line, eighteen below, the longest of which contained 52 scales. The anal spines gradually increase in length; the posterior, the longest, is less than ½ of the length of the succeeding ray. From the figure of *Pimelepterus boscii*, Lacepede (Cuv. and Val. Pl. 187), it would appear, that in that species the second and third anal spines are of equal length. At Pinang single individuals of the present species occur, but rarely, during all seasons. The flavour is said to be very good.

Genus PEMPHERIS, *Cuvier* 1829. Anal

fin long, scaly; dorsal short, elevated; head obtuse; eye large; opercle with a small spine; velvety teeth in the jaws, on the vomer and palatal bones.

(3758) *Pempheris molucca*, Cuv.

Syn. Pempheris molucca, Cuv. R. A. II. 195 (1).
Pempheris molucca, Cuv. and Val. VII 306.
Pempheris molucca, Temm. Schl. Fauna Japon. Pisc. 85, Pl. XLIV. Fig. 3.
Pempheris molucca, Richardson, Report 1845, 244.

Young. Head above and back pale metallic copper-coloured, lighter on the upper half of the sides; cheeks, opercles and abdomen silvery with golden and steel-blue reflections; all parts minutely dotted with brown, on the opercles and cheeks so closely as to acquire the appearance of a brown band following the posterior and the inferior margin of the orbit; lateral line pale orange; fins pale reddish yellow; the scaly portion of the dorsal, caudal and anal coloured and dotted like the body; the upper half of the dorsal spines and membrane so closely dotted with reddish brown, as to acquire a general brownish appearance. Iris pale golden round the pupil, the rest minutely and closely dotted with black. D 6/9, C 17$\frac{1}{2}$, A 3/42, V 1/5, P 19, Br. VII. Inhabits *Sea of Pinang*, Moluccas, Batavia, Japan. Total length: 3$\frac{1}{8}$ inch. The length of the head is contained 4$\frac{1}{3}$ times in the total: its greatest vertical diameter equals the length. The profile between the eyes is not convex, but somewhat concave, owing to a slight projection of the upper margin of the orbit, thus intersecting the profile. The diameter of the eye is a little less than $\frac{1}{2}$ of the length of the head; the orbit occupies the upper half, nearer the muzzle than the gill-opening. The greatest vertical diameter of the body, at the origin of the dorsal fin, is about $\frac{1}{3}$ of the total length. The stomach is thick, leathery, with four larger and two smaller appendicula cœcopylorica. The intestinal canal is $\frac{3}{4}$ of the length of the fish. The gall bladder is long, linear. The air-vessel large, thick; the anterior third is rounded joined by a constriction to the posterior oval portion. A single young individual was observed at Pinang in May 1845.

Genus TOXOTES, *Cuvier* 1817. Body short and compressed; dorsal fin placed on the posterior half of the back, with very strong spines; soft part of dorsal and anal scaly; muzzle depressed, short; lower jaw projecting beyond the upper; velvety teeth in the jaws, vomer, palatals, pterygoids and on the tongue; lower margin of infraorbital and preopercle finely toothed; branchiostegous rays 7.

(3759) *Toxotes jaculator*, (Pallas).

(3760) *Var. Toxotes malaccensis*, Cuv. and Val.

Syn. Cuv. and Val. VII. 320.
Ikan sumpit or Sa sumpit of the Malays.

Head above silvery olive green, brown or blackish, all the rest silvery buff or greyish; all the scales with minute brown dots, either spread or collected round the centre, so as to produce faint brownish longitudinal lines; along the side five large rounded spots: the first on the occiput in front of the opercle; the second behind the opercle, intersected by the lateral line; the third between the spiny and soft dorsal; the fourth close to the termination of the soft dorsal; the fifth at the upper half of the root of the caudal; above this series another of smaller black spots, viz. one between the first and second lower spots; another between the second and third; a third at the centre of the base of the soft dorsal; in some the upper series of spots is confluent along the back: some have a small black spot on the symphysis of the lower jaw. Dorsal spines and membrane either brownish black or greyish, minutely dotted with black; the soft dorsal silvery olive, with a large oblique black spot joining the third of the upper dorsal series; another spreading over the upper half of the posterior seventh or eight ray; margin of the soft portion black; caudal bright gamboge with a more or less distinct black, backwards arched band behind the root; upper half of anal silvery olive or greyish green, lower half black; pectorals and ventrals white, the latter with a large black spot, in some occupying nearly the whole space between the first and fourth ray. Iris bright gamboge or orange, blackish towards the orbit. D 5/12 or 13, C 17$\frac{1}{2}$, A 3/15, 16 or 17, V 1/5 P 13 or 14 Br. VII. Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Singapore*, New Guinea, Isle of Buru, Java, Malabar, mouths of the Ganges. Total length: 7 inch. This appears to be the variety, described by M.M. Cuvier and Valenciennes from a drawing in the series, formerly in the late Colonel Farquhar's possession. The food of several examined, consisted of remains of crustacea. In the Straits of Malacca this fish occurs, but not numerously, at all seasons. It is eaten by the Malays, who record its habits in the denomination: *ikan* signifying a fish, *sumpitan* a blow-pipe.

Fam. TÆNIOIDÆ.

Genus CEPOLA, *Linne* 1766. Body elongated, compressed like a sword-blade; dorsal and anal fins very long; caudal pointed; ventrals

attached under the pectorals; muzzle obtuse; jaws opening nearly vertically, with pointed teeth; the ventrals are the only fins preceded by a bony spine.

(3761) *Cepola abreviata*, Cuv. and Val.

Syn. Cepola abreviata, Cuv. and Val. X. 403.
Cepola variegata, Swainson II. Appendix, 402.

Head above carmine; cheeks and opercle paler; jaws, preopercle and throat silvery whitish; back deep flesh-coloured, paler, with silvery reflections on the sides and abdomen, pale bluish under the pectorals; lateral line silvery; along the middle of the sides a longitudinal series of about 14 round, distant, orange, or cornelian-red spots, gradually decreasing in size towards the caudal; dorsal and anal rose-coloured, deepening to crimson on the marginal half; and hedged throughout, dorsal at the posterior part, with dark purple; membranes sparingly dotted with brown; caudal rays black; membrane cornelian-red; pectorals transparent, ventrals white. Iris silvery rose-coloured, orbital margin black. D 72 or 74, C 13, A 74, V 1/5, P 19, Br. VI. Inhabits *Sea of Pinang*, Moluccas, Anjer (Java,) China. Total length: 7⅜ inch. The length of the head is ⅛ of the total; the depth at the occiput ¾ of the length. The distance from the muzzle to the eye is ⅕ of that from the muzzle to the point of the opercle. The diameter of the eye is ⅓ of the length of the head. In each jaw appears a single series of small pointed recurvous teeth, of which those near the symphysis are a little longer than the rest. There are about 24 on each side of the upper, 12 on each side of the lower jaw. On the lower margin of the preopercle appear five rather strong spines: two pointing obliquely backwards and downwards at the angle, and three, pointing forwards, along the margin. The cheeks and opercles are covered with scales, the rest of the head is naked. The vertical diameter at the pectorals nearly equals the length of the head; the diameter in front of the caudal is scarcely ⅙ of the former. They body is covered with small rounded scales, considerably larger, however, than in *Cepola rubescens*, Linne. The lateral line, like a thin cord, consists of keeled scales. It proceeds from the upper part of the gill-opening obliquely upwards to the fourth dorsal ray, from whence it accompanies the base of the dorsal fin to the termination, which latter is joined to the caudal. The length of the longest dorsal ray is ⅓ of the vertical diameter of the body. The anal commences opposite the eighth dorsal ray; the longest rays slightly exceed those of the dorsal. The pectorals are rounded, their length is $\frac{1}{14}$ of the total. The ventrals are situated a little in front of the pectorals, and are a little shorter; the first ray terminates in a filament reaching the anus, or origin of the anal fin; the fifth ray has three fourths of its length attached to the abdomen by a membrane. The caudal is pointed; its length is 11½ in the total. The stomach is small, but thickened. There are eight cæcopyloric appendages. The instestinal caudal is ⅓ of the length of the fish. The air-vessel is rather large, silvery. Two individuals occurred at Pinang in March and April 1845. The smaller, 4 inches in length, resembled the one just described, in colours and in the distribution of the spots; but it differed in the following dimensions. The length of the head was 6½ in the total, of which the caudal and the pectorals measured ⅓. Both head and these fins, therefore, were proportionally considerably longer in the smaller than in the larger individual. The specimen in the Zoological Society's Museum, London, described by Mr. Swainson, measnres one foot in length.

Fam. GOBIOIDÆ.

Genus GOBIUS, *Linne*, 1748. Head depressed with pores between the eyes; dorsal fins two, distinct, rays of both flexible; ventral fins united at the edges, forming a circle; vent with a tubercle; body covered with scales, the free edges of which ciliated; teeth small, numerous; branchiostegous rays five.

(3762) *Gobius elegans*, Kuhl. and Van. Hasselt, Var. Buff with a tinge of olive, minutely dotted with brown; the upper half of the sides with 3 or 4 indistinct lines, each formed by a series of very short brown streaks, beneath which a series of indistinct brown spots; a blackish spot at the posterior margin of the orbit; a second at the upper part of the root of the pectoral fin, and a third at the lower part of the root, spreading on the gill-membrane. Near the lower part of the root of the pectoral is a faint trace of a fourth brown spot. The membranes of the fins are of a very pale bluish green, minutely dotted with brown; those of the dorsals, particularly the second, with 3 or 4 indistinct series of blackish spots, and few similar on the caudal membrane. The rays of the anterior dorsal have 2 or 3 series of brown spots. Iris pale greenish silvery, minutely dotted with brown. D 6—1/9, C 15⅘, A 1/8, V 1/5, P 18, Br. V. Inhabits *Sea of Pinang*. Total length: 3⅘ inch. A single individual observed differs from *Gobius elegans*, Cuv. and Val. XII. 58. found in Vanikolo, New Guinea, Java, and Bombay, in having one soft ray less in the 2nd dorsal and anal-fins; and slightly in colours, which differences however appear not sufficient to constitute a distinct species.

(3763) *Gobius kokius*, Cuv. and Val.

Syn. Russell LI. Kohu.
Gobius kokius, Cuv. and Val. XII.
Gobius kokius, Jacquemont, Atlas: Pl. 14, Fig. 3?
Gobius kokius, Jerdon, Madras Journ. XV. 148.

Gobius kokius, Bleeker: Verh. Batav. Gen. XXII. 24, 5.

Head above and back greenish brown, sides pale reddish yellow; abdomen white; the back with 5 large, distant, brownish spots; 5 similar on the sides, the latter disposed beneath the intervals of the former. The rays and membranes of the dorsal and caudal fins with brown spots distributed in transversal series, which, however, are frequently very indistinct, and in some scarcely perceptible. One or two brown spots appear in some at the root of the pectoral fins, the membrane of which and of the ventral and anal fins is whitish. The lower half of the anal and caudal membrane is blackish in some individuals. Iris golden, in some dotted with black. D 6—1/9, C 16⅔ or 19/7, A 1/8, V 1/5, P 20 or 21, Br. V. Inhabits *Fresh-water and sea of Pinang*, Isle of France, Malabar, Coromandel, Orissa, Java, Madura. Total length: 8¼ inch. This species is closely allied to *Gobius giuris*, Buch. Ham. from which M. Valenciennes observes, it chiefly differs in the comparatively smaller eye, the diameter of which is ⅛ or ⅐ of the length of the head, while in *G. giuris* it occupies the second fourth of the length of the head.

(3764) *Gobius sublitus*, Cantor. Pale greyish brown, lighter on the sides, abdomen buff; back and sides with six indistinct parallel longitudinal streaks, produced by a short brownish line dividing each scale; fin-membranes minutely dotted with brown; anterior dorsal with a central transversal whitish waved band, and a similar at the base; second dorsal and caudal with 4 or 5 transversal series of oval whitish spots: and with a subterminal reddish white band; the posterior pointed part of this fin, as well as the outer half of the ventrals and pectorals, blackish. Iris pale golden. D 6—1/9, C 15⅔, A 1/8, V 1/5, P 19, Br. V. Inhabits *Sea of Pinang*. Total length: 3 inch. The head is elongated, ¼ of the total length, depressed; the breadth of the nape a little less than the depth, which equals ½ of the length of the head; the profile gently sloping: the cheeks and opercles tumid; the eyes are nearly vertical, occupying the second fourth of the head, and placed excessively close together; the muzzle pointed; the lower jaw slightly longer than the upper; the mouth very large, oblique, the angle situated beneath the posterior margin of the orbit. The teeth of both jaws are crowded, card-like, of unequal length, the external series shorter than the rest, distant, bent inwards. On each side of the symphysis of the upper jaw, on the internal series, is a pair of teeth in length exceeding all the rest. The anterior teeth of the inner series of the lower jaw are somewhat longer than the rest; the tongue is smooth flattened, crescent-shaped. The body is elongated, its greatest depth being about 6½ times in the total length. The scales are rather large, finely ciliated, with striæ converging towards the centre of the posterior margin. The longitudinal series, from the root of the pectoral to the caudal, contains about 38 scales. The height of the first dorsal is ⅛ of the total length; the fifth ray is slightly longer than the rest, and terminates in a short filament; the membrane is carried very close to the origin of the second dorsal, the height of which is ⅓ of the total length. In extent and height the anal is a little less than the former: the posterior extremity of both is pointed. The caudal, ventral and pectoral fins are a little pointed, of nearly equal length, ⅓ of the total. The species is not numerous: it appears to be closely allied to *Gobius bioccllatus*, Cuv. and Val. (XII. 73), but it differs in its dentition and the filamentous fifth ray of the anterior dorsal.

(3765) *Gobius apogonius*, Cantor. Back brownish, sides and abdomen buff, opercles minutely dotted with black. Back and sides with 5 or 6 parallel, sometimes interrupted, series of black spots; fin-membranes buff; on the anterior dorsal two elongated black spots, of which the posterior between the 4th and 5th ray; the second dorsal and anal fin with 2 or 3 transversal series of black stops, and with their free margins black; caudal edged with black with a number of somewhat irregular transversal series of black spots; ventrals with the extremities of the two central rays (the fifth) black. Iris pale golden, spotted with black. D 6—1/8, C 15/7, A 1/8, V 1/5, P 18, Br. V. Inhabits *Sea of Pinang*, Total length 2⅜ inch The general outline, the short robust make, and the large scales impart to this species a certain resemblance to the Genus *Apogon*. The head is about ¼ of the total length, depressed, sloping; the muzzle broad, rounded; the eyes are lateral, near the upper profile, occupying the second fourth of the head; their distance across the head, and that from the lower margin of the orbit to the angle of the mouth, equals the diameter of the eye, or one fourth of the length of the head. The jaws are nearly semi-circular, the lower slightly projects beyond the upper; the mouth is obliquely cleft, the angle situated under the middle of the orbit. The teeth of both jaws are velvety, the external series of the upper consists of a few distant teeth, slightly larger than the rest; in the lower jaw there is a similar internal series, of which the two nearest the symphysis have the appearance of small canines. The tongue is thin, narrow, crescent-shaped, and smooth. The profile of the forehead rises obliquely towards the first ray of the anterior dorsal, where the vertical diameter equals about ⅓ of the total length; from thence the arched profile of the back and abdomen gradually converge towards the last ray of the second dorsal and anal fins, the vertical diameter between which equals ⅙ of the total length, and such it continues to the root of the caudal. The height of the first ray of the anterior dorsal

fin equals one half of the greatest vertical diameter; the second and third rays gradually increase; the fourth terminating in a filament, slightly excedes the greatest vertical diameter of the body; but the sixth ray scarcely equals half the height of the first. The second dorsal and the anal fin are nearly opposite, on a backwards sloping level, their extent being somewhat less than $\frac{1}{5}$ of the total length. Their sixth, divided, rays, are the longest and equal about one-sixth of the total length. Their first and last rays are about $\frac{1}{9}$ of the total length. The distance between the anterior and second dorsal is about $\frac{1}{3}$ of that between the latter and the caudal fin. The latter is rounded, about $\frac{1}{4}$ of the total length. The pectoral fins are rounded, nearly as long as the caudal, and with the rays slightly filamentous. The ventrals are a little pointed, and scarcely exceed one half the length of the pectorals. The scales are generally very large, particularly on the crown of the head, and the opercles finely ciliated, and striated; their breadth double their length. The longitudinal series, from the root of the pectoral to the caudal, contains about 25 scales; the sides behind the second dorsal and the anal fins are covered by 5 vertical series. A few individuals were occasionally observed among the fishes taken in the stakes off the coast of Pinang. This species is closely allied to another from the estuaries near Calcutta: *Gobius sadanandio*, Buchan. Ham. (*Gangetic Fishes*, 52,366) among whose duplicate series of drawings there is a representation. In the number of rays and the large size of the scales both agree, and the black markings of the fins and the body are also nearly the same. But *G. sadanandio* is of a strikingly more elongated shape, the third ray of the anterior dorsal fin is the longest, and the fourth is shorter not terminating in a filament. *Gobius filosus*, Cuv. and Val, (XII. 78) appears also to be allied to the present species.

(3766) *Gobius acutipennis*, Cuv. and Val., Var. [XII. 80.] Brownish buff with some indistinct blackish coloured spots on the back and sides; fin-membranes bluish white, minutely dotted with black; the two dorsals and the upper third of the caudal with indistinct transversal series of blackish spots. Iris blackish silvery. D 6—1/12, C 17, A 1/13, V 1/5, P 22, Br. V. Inhabits *Sea of Pinang*. Total length: $3\frac{3}{8}$ inch. The rays of the first dorsal gradually increase towards the fifth, which terminates in a filament, in length slightly exceeding $\frac{1}{3}$ of the total. The second dorsal and the other fins are pointed; the length of the caudal is $\frac{1}{5}$ of the total; that of the head slightly exceeds $\frac{1}{6}$. In both jaws the teeth are placed in a single series; those of the upper are a little longer and more distant than those of the lower; there are no canines. *G. acutipennis*, Cuv. and Val. has 10 branched rays in the second dorsal and 11 in the anal. But in proportions and colours it closely agrees with the present.

(3767) *Gobius criniger*, Cuv. and Val.

Syn. Gobius criniger, Cuv. and Val., XII. 82.

Pale ochreous with faint silvery lustre; abdomen whitish; head and upper jaw black; three round black spots on the cheeks; a fourth larger at the posterior angle of the orbit; a similar on the operele; on the sides three large rounded black spots: the anterior behind the pectoral fin, spreading on the back; the second below the posterior part of the second dorsal, and the third at the root of the tail. Between these spots several smaller, irregular black marks. The fin-membranes whitish, that of the ventrals minutely dotted with black. That of the two dorsals and the caudal with rather large black spots; the free margin of the caudal and anal black. Iris pale golden, blackish. D 6—1/9, C $13\frac{3}{4}$, A 1/9, V 1/5, P 17, Br. V. Inhabits *Sea of Pinang*, New Guinea, Malabar. Total length $2\frac{3}{4}$ inch. The occiput and the opercles are without scales; the rest of the body with large ciliated, faintly striated scales, of which the longitudinal series from the root of the pectoral to the anterior part of the caudal contains about 34. The length of the head is about $\frac{1}{4}$ of the total. The second ray of the anterior dorsal is the longest, terminating in a filament; its length is double that of the greatest vertical diameter, or a little less than $\frac{1}{4}$ of the total length. The teeth are minute, velvety, of nearly equal length. This species appears not to be numerous at Pinang.

(3768) *Gobius Cyanoclavis*, Cantor. Greenish-grey, paler on the abdomen; the scales with a central azure spot, forming on the body from 5 to 8 longitudinal series; the operele and root of the pectorals with a few similar spots; anterior dorsal minutely dotted and clouded with brown; second dorsal black, pale at the base, upper margin orange, between the rays 4 to 5 white oval spots, forming transversal series; caudal similarly coloured, but with the upper half of the posterior margin orange; anal intenses, ventrals and pectorals paler black, the anterior margin of each of the anal branched rays accompanied by a blue streak. Genital papilla with an orange coloured apex. Iris golden, spotted with black; pupil strongly iridescent. D 6—1/10, C $17\frac{1}{6}$, A 1/10, V 1/5, P 19, Br. V. Inhabits, *Sea of Pinang*. Total length: 6 inch. The head is a little depressed, the profile slightly sloping, the length $\frac{1}{5}$ of the total; the breadth at the nape is contained $2\frac{1}{3}$ times in the depth, which exceeds one half of the length of the head; the cheeks are tumid; eyes obliquely oval, nearly vertical, situated nearer the posterior angle of the preopercle than the muzzle; their greatest diameter is about $\frac{1}{5}$ of the length of the head; their distance $\frac{1}{3}$ of the greatest diameter; the muzzle is bluntly rounded, the lower jaw slightly projecting beyond the upper; the gape is wide, the angle of the mouth is beneath the posterior margin of the orbit. The teeth of the

upper jaw are generally minute, but the anterior 4 or 5 on each side a little longer than the rest; the external series on each side of the lower jaw consists of 9 teeth, of which the two last towards the angle of the mouth are stronger, and much longer than the rest, and recurvous. These teeth M. Valenciennes compares with the fangs of venomous serpents. The other teeth are minute like those of the upper jaw. On the lower part of the margin of the preopercle appear five pores of which the two upper ones are a little larger than the rest. The scales of the nape, of the opercle and of the root of the pectorals are much smaller than those of the body which are very large, finely ciliated and striated. The longitudinal series from the root of the pectoral to the caudal contains about 32 scales. All the rays of the anterior dorsal terminate in filaments; the third is the longest, equalling nearly half the total length; next to that is the fourth ray; the sixth is the shortest, but all except the third, are liable to individual variations. The posterio dorsal and anal fins are pointed, increasing in height towards the last, double, ray, which is about $\frac{1}{6}$ of the total length. The caudal is contained $4\frac{1}{2}$ times, the pectorals and ventrals 6 times in the total length: all these fins are broad, and a little pointed. The species is of no uncommon occurrence: it is closely allied to *Gobius caninus*, Cuv. and Val. (XII. 16).

(3769) *Gobius Russus*, Cantor. Flesh or pale salmon-coloured; back blackish; on each side 4 or 5 large clouded blackish spots, the scales of which have a minute vertical lanceolate whitish spot in the centre; first dorsal whitish at the base and of the upper magin, with two transversely waved blackish bands, separated by a white, which surrounds a large black spot between the 4th and 5th rays; posterior dorsal whitish, minutely dotted with brown, and with two irregular transversal series of pale blackish, clouded, spots; rays of dorsals and anal flesh-coloured; membranes of caudal, anal, ventral and pectoral fins whitish, minutely dotted with brown. Iris pale golden, spotted with black. D 6—1/10, C 19$\frac{1}{2}$, A 1/10, V 1/5, P 18, Br. V. Inhabits *Sea of Pinang*. Total length: 4$\frac{3}{8}$ inch. The head is depressed, the profile slightly sloping from the eyes; the length equals that of the caudal, and is contained about 4$\frac{1}{2}$ times in the total length; the breadth at the nape is a little less than the height which is about $\frac{1}{4}$ of the total; the cheeks tumid; the eyes oval, lateral, situated on the profile, occupying a little more than the second fourth of the head, nearer the muzzle than the angle of the preopercle; the muzzle is broad rounded; the lower jaw a little longer than the upper; the gape is wide, oblique, the angle is situated beneath the middle of the orbit. The teeth are velvety; the 4 anterior on each side of the upper jaw are distant and longer than the rest. The external series of the lower jaw consists of five similar teeth on each side, the last of which is slightly recurvous, but in length scarcely exceeding the four anterior. The space between the nape and the anterior dorsal is naked; the rest of the body is covered with small ciliated, striated scales, which are indistinct and almost hidden in the skin. The rays of the anterior dorsal terminate in short filaments; the first is the longest, scarcely exceeding the vertical diameter at the nape, or about $\frac{1}{8}$ of the total length; the membrane closely approaches the posterior dorsal, which, as well as the anal, slightly increases in height towards the 9th branched ray, the length of which equals the first ray of the anterior dorsal. The caudal, ventral and pectoral fins are broad, slightly pointed; the length of the two latter is little more than $\frac{1}{7}$ of the total. The species is not numerous: it closely approaches *Gobius phalana* Cuv. and Val. (XII. 92).

Genus APOCRYPTES, *Cuv. and Val.* 1837. Scartelaos, *Swainson*, 1839 [By mistake characterised as being destitute of scales.] Ventral fins united as in *Gobius;* two dorsals; body elongated; caudal long, pointed (lanceolate); teeth pointed, distant, in a single series in both jaws, near the symphysis of the lower two teeth a little behind the rest; scales small.

(3770) *Apocryptes lanceolatus*, (Bloch-Schneider).

Syn. Eleotris lanceolata, Bloch-Schneider, 67, Pl. 15.
Gobius changva, Buchan. Ham. 41,365, Pl. 5. Fig. 10.
Apocryptes changva, Cuv. and Val. XII. 145.
Scartelaos calliurus, Swainson, II. 280.
Apocryptes changva, Bleeker: Verh. Batav. Gen. XXII. 36, 5.

Head, cheeks and opercles blackish olive, bluish beneath; back blackish olive; sides greenish or bright gamboge mottled with blackish; abdomen whitish or rose-coloured; dorsal fins minutely dotted with black. The rays of the second in some with brownish spots; in the young both are transversely waved with pale brown; caudal with alternate vermiculated brownish and without lines, and at the upper part of the root a black ocellated spot; anal, ventrals and pectorals buff or pale yellowish. Iris buff. D 5—1/30 or 31, C 17$\frac{1}{2}$, A 1/29, V 1/5, P 18, Br. V. Inhabits *Estuaries of Pinang, Malayan Peninsula, Singapore*, Batavia, Madura, Rangoon, Pondicherry, estuaries of the Ganges. Total length: 6$\frac{1}{8}$ inch. The species is numerous at Pinang.

(3771) *Apocryptes nexipinnis*, Cantor.

Slate-coloured, lighter on the abdomen; throat bluish white; fin membrane of the united dorsals and of the caudal minutely dotted with brown,

giving the fins a greyish appearance; anal and ventrals transparent, pectorals blackish grey, divided in the middle by a crescent-shaped transparent band, which expands over the lowest eight rays. Iris slate-coloured. D 6/26, C 17½, A 1/25, P 21. Br. V. Inhabits *Sea of Pinang*. Total length: 3⅜ inch. The head is depressed, gently sloping before the eyes; the breadth at the nape exceeds the vertical diameter by one third, and equals ⅓ of the length of the head; the latter is ¼ of the total length; the eyes are vertical, oval, occupying the third seventh of the length of the head; their distance is somewhat less than their diameter. The muzzle is rounded, the lower jaw slightly projects beyond the upper; the gape is enormous, almost horizontal; the angle of the mouth marks the anterior half of the length of the head. The anterior tooth on each side of the symphysis of the upper jaw is excessively long, curved and projecting beyond the lower jaw when the mouth is closed. At a distance from these canines commences on each side a single series of 12 to 14 smaller, distant teeth, placed almost horizontally, and arched downwards. The thin membranous upper lip covers all the teeth except the two foremost, and has a small downwards pointed lobe beneath the anterior angle of the orbit. The lower jaw has on each side a single series of 10 to 12 distant teeth, horizontally placed and bent upwards. The first on each side of the symphysis is placed a little behind the rest, and it is the smallest; the succeeding four gradually increase in length; the two last are the longest of the series, which terminates with the anterior half of the jaw, and, considerably in front of the teeth of the upper jaw. The tongue is very narrow, almost linear, short, smooth, rounded in front and tied to the floor of the mouth. It is of a buff colour, but the cavity of the mouth is inky. The scales of the nape are very small and deciduous, so as to make the part appear naked; they gradually increase in size towards the posterior part of the body, where they are very large. They are orbicular with about 16 striæ. The body is compressed, the profile gradually narrowing towards the tail. The first dorsal ray is situated at the second third of the total length: its height is about ⅓ of the vertical diameter at the nape; the succeeding, undivided, rays gradually increase towards the 5th, which, as well as the 6th are about ⅔ of the vertical diameter at the nape. The distance between the 5th and 6th, undivided, rays, and between the latter and the first branched ray is conspicuously greater than the distances between any of the preceding or following dorsal rays. The first branched ray is somewhat shorter than the 6th undivided, which produces a sinking in the upper margin of the connecting membrane, and indicates the transition from the undivided to the branched rays. The latter gradually increase in length towards the penultimate, which nearly equals the vertical diameter at the nape. The caudal is broad lanceolate, its length about ⅓ of the total. The first undivided ray of the anal is situated opposite the 3d branched dorsal; the height of the fin is slightly less than that of the dorsal. The papilla immediately behind the anus is short, conical. The ventrals are rounded, their length equalling the vertical diameter at the nape; the transversal diameter exceeding the latter by one third. The pectorals are pointed, their length ⅓ of the total. It is not numerous at Pinang. Although the dorsal fin is single, as it is in *Gobioides*, Lacepede, this species has the characteristic dentition of *Apocryptes*: it is in fact an *Apocryptes* with the two dorsal fins united, and as above observed, with the junction perceptible. The single character is of too little value to warrant the formation of a separate genus, particularly, as in *Apocryptes dentatus*, Cuv. and Val. (XII. 112) the membrane of the anterior dorsal is continued to the base of the second.

Genus TRYPAUCHENA, *Cuv. & Val.* 1837. Ventral fins united as in *Gobius*; the single dorsal, the caudal and anal united; on each side of the nape above the opercle a deep fossa.

(3772) *Trypauchena vagina*, (Bloch).

Syn. Gobius vagina, Bloch-Schn. 73, No. 20.
Gobioides ruber, Buchan. Ham., 38, 365.
Trypauchena vagina, Cuv. and Val. XII. 153. Pl. 351.

Trypauchena vagina, Richardson, Report 1845, 206.
Trypauchena vagina, Bleeker: Verh. Bat. Gen. XXII. 37, 5.

Rose-coloured with light blue reflections, paler towards the abdomen which is whitish; eyes minute, barely preceptible, like two blackish points; fins transparent, colourless. D 6/47 to 49, C 17, A 1/49, V 1/5, P 17, Br. VI. Inhabits *Sea of Pinang*, Sea, estuaries and fresh-water of Bengal, Coromandel, Malabar, China Seas, Java, Madura, Balli. Total length: 8 inch. Not numerous at Pinang.

Genus AMBLYOPUS, *Cuv. and Val.* 1837. [Substituted for *Tænioides*, Lacepede 1800, the definition of which, M. Valenciennes observes, is incorrect, and not complete.] (Psilosomus, *Swainson*, 1839). Body elongated; ventrals like *Gobius*; dorsal, caudal and anal fins united; mouth vertical; in both jaws an external series of exposed, curved, distant teeth, longer than the rest; eyes very minute, hid by the skin, scarcely perceptible; no fossæ on the sides of the nape.

(3773) *Amblyopus hermannianus*, (Lacepede).

Syn. Tænioide hermannien, Lacepede, IV. 533.
Cepola hermanniana, Shaw, IV. 191.

Amblyopus hermannianus, Cuv. and Val. XII. 159, Pl. 350.
Psilosomus, Swainson, II. 183.
Amblyopus hermannianus, Swainson, II. 279.

Head and back brownish ochre; sides brick-red, paler on the abdomen, fins reddish ochre, caudal in some blood coloured. D 6/44, C 15, A 1/45, V 1/5, P 15, Br. V. Buchanan Ham.: D 46, A 40, V 12. Cuv. and Val.: D 6/40, C 15, A. 1/37, V 1/5, P 15. Inhabits *Sea of Pinang*, Estuaries and fresh water of Bengal, Rangoon, Tranquebar, Peiho river. Total length: 1 ft. 2 inch. The height at the nape is from $\frac{1}{13}$ to $\frac{1}{17}$ of the total length; the length of the head is $\frac{1}{7}$ to $\frac{1}{8}$ of the total; the length of the pectoral fin is $\frac{1}{27}$ to $\frac{1}{29}$ of the total, and $\frac{1}{3}$ of that of the ventrals. It is of no common occurrence at Pinang.

Genus PERIOPHTHALMUS, (*Bloch-Schn.* 1801) *Cuv. and Val.* 1837. Profile rapidly sloping at an obtuse angle where the eyes are situated; the latter are very close to each other, provided with a lower lid capable of covering the eye. Ventral fins in some entirely united, in others partially at the basal half; pectorals muscular at the base, covered with scales and appearing as if supported on arms. Teeth of both jaws in a single series, more or less horizontally placed.

(3774) *Periophthalmus schlosseri*, (Pallas).

Periophthalmus schlosseri, Bleeker, Verh. Bat. Gen. XXII. 39.
Ikan lásah, lísah, or leésah of the Malays. [*Lásah*, restless].

Upper part of the head and back blackish green or olive, cheeks and sides greenish gamboge, the scales with blackish edges and a large blackish spot at the upper angle of the opercle; throat and abdomen white. Interior dorsal shining reddish brown, the upper margin whitish; second dorsal: upper margin and basal half brownish white, in the middle a broad obliquely upwards turned black band; posterior part of the pectorals and caudal black; anal and ventrals whitish. Iris black with a narrow internal golden ring; eyes strongly iridescent. D 8—1/2, C $16\frac{6}{6}$, A 1/12, V 1/5, P 17, Br. V. Inhabits *Estuaries of Pinang, Malayan Peninsula, Singapore*, Amboina, Sumatra, Java. Total length: $16\frac{1}{2}$ inch. Some individuals have on one or both sides of the symphysis of the upper jaw a second internal, short series of two or three small teeth. At Pinang this species occurs in great numbers in the moat of Fort Cornwallis, which is filled by each tide from the sea. Like the other Gobies it is very wary and difficult to capture, but unlike most of the others, it is very fierce when taken, and is capable of inflicting rather severe wounds with the long hooked teeth.

Genus BOLEOPHTHALMUS, *Cuv. and Val.* 1837. Differs from *Periophthalmus:* in having all or the middle teeth of the upper jaw straight and strong; those of the lower jaw placed horizontally, all very fine, except two stronger than the rest, recurvous, and placed a little inwards; head more oblong than *Periophthalmus*; scales small or imperceptible; anterior dorsal fin with five rays; the base of the pectorals not in all species covered with scales.

(3775) *Boleophthalmus Boddaerti*, (Pallas).

Boleophthalmus boddaerti, Bleeker: Verh. Bat. Gen. XXII. 40, 5.

Lips, upper part of the head and the back blackish green; sides greenish gamboge; abdomen white; the sides from the second dorsal with 6 or 7 obliquely backwards directed blackish bands, (not reaching the abdomen); the whole body, pectorals and caudal with numerous verdigris spots; anterior dorsal pale brownish lilac with violet spots, the upper margin between the first four rays whitish second dorsal brownish, whitish towards the base, between the rays two or three transversal violet bands edged with white, forming irregular transversal series; caudal with blackish rays; anal and ventrals whitish; pectoral membrane blackish. Eyes black, strongly iridescent. D 5—1/24 to 26, C 16, A 1/25, V 1/5, P 19, Br. V. Inhabits *Estuaries and Sea of Pinang, Malayan Peninsula*, Madura, Borneo, Java, Sea of China and Japan, Moluccas, Bengal, Coromandel, Malabar. Total length: 5 inch. At Pinang the species is very numerous in the same localities as *Periophthalmus Schlosseri.*

(3776) *Boleophthalmus pectinirostris*, (Linne.)

Syn. Gobius pectinirostris, Linne: Chinens, Lagerstr.—Amoen. Acad. Dec. 1754.
Apocryptes chinenses, Osback: It. 130.—Amoen. Acad. IV, Pl. 3, Fig. 3.

Gobius pectinirostris, Shaw IV. 245.
Apocryptes pectinirostris, Cuv. and Val. XII. 150.
Boleophthalmus pectinirostris, Richardson Report 1845, 208.

Head and back greyish green, lighter on the sides; abdomen whitish; the whole body with minute blackish tubercles, and with metallic sky-blue or verdigris spots; muzzle, lips, throat and posterior margin of the opercle pale greenish black; anterior dorsal greenish black with numerous vertically placed lilac spots; posterior dorsal greenish black with 6 or 7 transversal series of elongated lilac, black-edged spots, which between the 8 posterior rays become larger, but rarer; caudal brownish black with transversal series of indistinct lilac spots; anal, ventral and pectoral fins brownish; the base of ventrals greenish black, the anterior scaly part of the pectorals with a blackish crescent-shaped margin. Iris narrow golden; pupil strongly iridescent. D 5—1/25, C 16⅔, A 1/25, V 1/5, P 20, Br. V. Inhabits *Sea coast of Pinang*, Canton. Total length: 6 inch. The length of the head is a little more than ⅓ of the total length, the height slightly exceeds the breadth and equals half the length. The vertical diameter at the anterior dorsal is ½ of the total length. The muzzle is rounded, the gape wide, the angle of the mouth is opposite the posterior angle of the orbit. The eyes are contiguous, situated a little behind the second fifth of the head; upper eyelid with tubercles; the lower membranes, hemi-transparent. The upper jaw has on each side of the symphysis three conical teeth, distant, and longer than the rest, of which there are upwards of 30 very minute, and distant, on each side. On the upper lip behind the canines appears a small flattened lobe. Each side of the lower jaw carries 30 to 34 horizontal, closely set teeth, which are long, almost setaceous, obliquely truncated at the apex. On each side of the symphysis, on a more inward level than the others is a stronger, conical, vertical tooth. The tongue is small, rounded, fleshy, and fixed to the floor of the cavity, and as well as the latter inky. The anterior dorsal commences a little behind the root of the pectoral; the four posterior rays are filamentous: the third, the longest, is little less than ⅓ of the total length; the fifth, a little shorter than the first, equals about the one half of the third; the membrane extends close to the posterior dorsal; the base of this fin equals the greatest vertical diameter of the body. The posterior dorsal slightly increases in height towards the 21st ray, which measures about ⅔ of the greatest vertical diameter of the body; the base of the fin is 3½ times its height. The caudal is a little pointed, the length little less than ⅓ of the total. The anal commences opposite the second branched ray of the posterior dorsal, the tract of which it follows, but its height is less by one third; the 23rd ray is the longest and less than one half of the greatest diameter of the body. The ventrals are infundibuliform, their length is about ⅕ of the total. Two thirds of the pectorals are covered with scales; their length is about ⅓ of the total; the naked portion of this fin is oval. The scales resemble those of *B. boddaerti*, increasing in size on the abdomen and posterior part of the body, deeply imbedded in the integuments, which are covered with numerous papillæ. Single individuals were observed at Pinang.

(3777) *Boleophthalmus viridis*, (Buchan-Ham.)

Syn. Gobius viridis, Buchan. Ham. 42, 45, 366, Pl. XXXII. Fig. 12.
Boleophthalmus viridis, Cuv. and Val. XII. 213.
Boleophthalmus histophorus, Cuv. and Val. XII. 210.
Scartelaos viridis, Swainson II, 280,

Head and back greenish; sides bluish-slate coloured; above the indistinct lateral line more or few distant black dots; in some a varying number of blackish vertical lines; the festooned lips, the throat and abdomen bluish white; dorsal fins greenish grey edged with black, the posterior one dotted with black: caudal similar, but the black dots forming a few undulating transversal lines; anal and ventrals pale rose coloured or whitish: pectorals greyish with a few scattered black dots. Iris pale golden. D 5—1/26 C 17, A 1/25, V 1/5 P 17, Br. V. Inhabits *Sea of Pinang*, Estuaries of the Ganges, Bombay, Surat. Total length: 5 inch. From comparison of a number of living individuals it appears that the deeper or lighter greenish colour of the back, and the absence or presence of vertical lines on the sides are but individual differences, perhaps influenced by age, sex, or habits. Buchanan Hamilton correctly observes "there are very minute scales on the body and upper part of the head." They are imbedded in the skin, distant, orbicular or slightly oval, and become larger towards the tail. On submitting a portion of the skin to 60 or 100 linear magnifying power, the scales may be seen distinctly enough. This species is very numerous at Pinang,

Genus ELEOTRIS, *Gronov.* 1763. General structure of *Gobius*, but the ventral fins are not united; branchiostegous rays six.

(3778) *Eleotris porocephala*, Cuv. and Val.

Syn. Eleotris porocephal, Cuv. and Val. XII. 237.

Head and back blackish brown; sides brownish white with clouded brownish spots; abdomen

brownish white minutely dotted with brown; anterior dorsal pale brownish; posterior dorsal and caudal darker with indistinct transversal series of brownish spots, their free margin whitish; anal, ventrals and pectorals whitish hemi-transparent. Iris golden, more are less spotted with black. D 6—1/8, C 17$\frac{6}{8}$, A 1/7, V 1/5, P 15, B. VI. Inhabits *Freshwater Pinang*, Freshwater Seychelle Islands, New Ireland. Total length: 5$\frac{1}{2}$ inch. The pore a little above the posterior nostril, and that immediately behind the orbit are indistinct in the two young individuals examined; the uppermost of the four pores on the posterior ascending margin of the preopercle is distinct, the other three less so, confluent, forming a short sulcus.

(3779) ***Eleotris ophioccephalus***, Kuhl and Van Hasselt.

Syn. Eleotris ophiocephalus, Cuv. and Val. XII. 239.

Head and back pale brownish black on a golden ground; sides with six parallel longitudinal brown lines; abdomen buff, minutely dotted with brown; dorsal brownish; the posterior and the caudal with indistinct transversal series of brownish spots, and with whitish margins; anal, ventrals and pectorals hemi-transparent, minutely dotted with brown. Iris golden blackish. D 6—1/8, C 17$\frac{5}{8}$, A 1/7, V 1/5, P 15, Br. VI. Inhabits, *Sea of Pinang*, Java. Total length; 5$\frac{6}{8}$ inch. From *E porocephala* the present species principally differs in its colours: the head appears a little more elongated, the scales of the crown somewhat larger, and the inferior margin of the preopercle has but a single rather indistinct pore, near the angle of the mouth. It appears to be of rare occurrence at Pinang.

(3780) ***Eleotris Butis***, (Buchan. Ham.)

Syn. Cheilodipterus butis, Buchan. Ham. 57.367.
(*Icon.*) Cheilodipterus butis, Gray. ILL. Ind. Zool. II. Pl. 93. Fig. 3
Eleotris humeralis Cuv. and Val XII. 246.
Eleotris humeralis, Bleeker: Verhand. Batav. Gen. XXII. 22. 5.

Reddish brown with dark central spots on some of the scales of the head and sides, and the latter with numerous vermilion spots; the two dorsals brownish at the base, transparent in the middle with the broad vermilion margins; caudal and anal black with vermilion margins; anal rays with similar spots; pectorals transparent; near the root, between the 8th and 16th ray, a large rounded black spot, above and below which a smaller vermillion spot, and a few others at the root of this and the ventral fins. Iris blackish golden. D 6—1/8, C 17$\frac{5}{8}$, A 1/8, V 1/5, P 18, Br. VI. Buchanan Hamilton gives by mistake 7 branchiostegous rays. Inhabits *Sea and estuaries of Pinang*, Estuaries of Bengal, Batavia, Samarang, Surabaya, Pasuruan, West Coast of Madura. Total length: 6 inch. It is readily recognised by the much depressed elongated head, the length of which is contained 3$\frac{1}{2}$ times in the total; the greatest verticle diameter of the body slightly exceeds $\frac{1}{6}$ of the total length. The opercle is a little pointed above the root of the pectorals, which, however, is less perceptible in the young than in the adult. Although Buchanan Hamilton points out the strong affinity of this species to the Gen. *Gobiomorus*, Lacepede, he was led to consider it a *Cheilodipterus*. His specimen from the Ganges, figured in his unpublished drawings, and later by Mr. Gray, was destitute of the vermilion spots of the body, which vanish in individuals inhabiting muddy estuaries. These spots as also the scarlet margins of the fins, become obliterated after death, when the black spot of the pectoral fins appears surrounded by two smaller yellowish-white ones, as described by M. Valenciennes. (Hist. Nat. des Poiss. XII. p. 186.) It is not numerous at Pinang.

(3781) ***Eleotris caperatus***, Cantor. Ground-colours, the vermillion spots of the body and the margins of the fins, the black spots at the root of the pectorals exactly resembling those of *Eleotris butis*. D 6—1/8, C 16$\frac{4}{4}$, A 1/8, V 1/5, P 21, Br. VI. Inhabits *Sea of Pinang*. Total length: 3$\frac{2}{8}$ inch. The crown of the head is apparently scaleless as far as the posterior margin of the orbit; it is depressed, but less elongated than *E. butis*, its length being contained 4$\frac{1}{2}$ times in the total; the opercles expansible and cleft as in *E. butis*. The muzzle is rounded, the gape nearly vertical, the angle of the mouth opposite the anterior part of the orbit; the lower jaw scarcely longer than the upper; the teeth minute, velvety, the external and internal series of both jaws distant, somewhat longer than the rest; the tongue small, flattened, rounded in front; the eye oval, comparatively larger than in *E. butis*, occupying the second fourth of the head; the distance between both is about one vertical diameter. The upper margin of the orbit forms a sharp arched crest, armed with minute, close, forwards pointing spines; the crest itself is continued obliquely downwards, but becomes spineless in front of the orbit, and there it separates the rostral cavity in which the two nostrils open, from a short crescent-shaped cavity, immediately below the anterior angle of the orbit. Along the upper margin of the somewhat pointed preopercle proceeds a short, but rather deep, horizontal sulcus, which farther follows the tract behind the supraorbital spinous crest. The greatest vertical diameter of the body, at the commencement of the anterior dorsal fin, is a little less than the length of the head. The scales of the opercles, cheeks and the nape are a little smaller than those of the body, which are a little broader than long. The longitudinal series from the root of the pectorals to the caudal contains about 34 scales. The length of the

pectoral fins equals that of the head; the other fins, as well as the genital papilla in shape and proportions resemble those organs of *E. bitis*. The similarity of colours and their distribution is so striking in both species, that they might be mistaken, but for the supraorbital spinous crest, the sulcated, and comparatively shorter head of *E. caperatus*. Two individuals were observed at Pinang, taken together in stakes with other fishes.

Subfam. ECHENEIDINÆ.

Genus ECHENEIS, ([*Artedi*,] *Linne* 1748), *Cuvier* 1817. With a flattened disk on the head, composed of a certain number of transversal laminæ, directed obliquely backwards, dentated or spiny on their posterior margin, and moveable so that by creating a vacuum between them, or by hooking on by the spines, they are capable of attaching themselves to various bodies such as rocks, ships, fishes, &c. Body elongated covered with minute scales; a single soft dorsal opposite to the anal; head perfectly flat above; eyes lateral: mouth, horizontally cleft, rounded; lower jaw projecting and as well as the intermaxillaries furnished with minute card-like teeth; a regular series of minute teeth like cilia along the margin of the upper maxillaries: branchiostegous rays eight; the stomach is a wide cul-de-sac; cæca six or eight; intestine ample, but short; air-vessel none.

(3782) *Echeneis naucrates*, Linne.

Guddimi of the Malays.

(*Adult.*) Disk, fins, and ground-colour of body livid or lead colour of different shades; from the muzzle over the side of the head a broad bluish black band, in some more or less continued along the lateral line; in some the throat and posterior half of the body bluish black; in others livid patches on the sides and abdomen; upper and lower corner of the caudal with a crescent-shaped or triangular milk-white spot. Iris silvery bluish black. (*Young*). Of darker colours than the adult; the elevated angles of the dorsal and caudal milk-white as also the angular spots on the trapezoidal caudal. D 2/33 to 38, C 17½, A 2/33 to 38, V 1/5, P 21, to 23, Br. IX. Disks 23 to 26. Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Singapore*, Atlantic on both sides, Red Sea, Indian Ocean, Bay of Bengal, Sumatra, Australia, Polynesia, Japan. Total length: 2 ft. 4 inch. Single individuals occur at all seasons in the Straits of Malacca. The Malays consider this fish to be powerful manure for fruit trees. (Low.: *Dissert. of Pinang*, 179).

Fam. BLENNIOIDÆ.

Genus PETROSCIRTES, *Ruppell* 1823. (Omobranchus, [*Ehrenberg*], *Cuv. and Val.* 1836. —Blennechis, *Cuv. and Val.* 1836). [*Blennechis*, Cuv. and Val.—"Branchiostegous membrane closed beneath and communicating externally by a small fissure above the base of the pectoral fins: dentition a modification of that of *Blennius*: lower incisors, attached to the anterior part of the jaw; on each side a long canine, in some species enormous, reclining; in others arched, and when the mouth is closed, fitting in a cavity on each side of the palate; dorsal undivided; tentacles absent in most." (Cuv. and Val. XI. 279).—Of the two species of *Petroscirtes*, described by Dr. Ruppell, *P. mitratus* is characterized as having in both jaws a single close series of the setaceous teeth; *P. ancylodon* as having in addition two small canines on each side of the upper jaw, and a very long one on each side of the lower. As M.M. Cuvier and Valenciennes admit both species in their Genus *Blennechis*, Dr. Ruppell's *Petroscirtes* claims priority.] Teeth setaceous, minute, in a single series; branchial opening very small, placed above the pectoral fins; dorsal single, with flexible, but not articulated rays; ventrals thoracic, with three rays.

(3783) *Petroscirtes variabilis*, Cantor. Head above and back light brownish olive; sides of the head and body yellowish; abdomen greenish yellow; from the orbit to the caudal a longitudinal blackish band, above which the head and body minutely dotted and clouded with black; dorsal yellowish olive, dotted with black, rays with more or less distinct blackish spots forming two or three longitudinal series; in some individuals a black spot between the points of the first and second ray; caudal yellow, base minutely dotted with black and in some with a central black spot; anal yellow minutely dotted with black, in some with black spots on the rays forming two or three longitudinal series; ventrals yellow; pectorals transparent. Iris bright yellow clouded with blackish; orbital margin olive. D 11/17 to 20, C 11½, A 17 to 21, V 3, P 15, B. VI. Inhabits *Sea of Pinang*, *Singapore*. Total length: 5 inch. The form of the body is elongated, gradually compressed from the head to the tail; the greatest vertical diameter of the body, in front of the anal, is ⅓ of the total; of which that in front of

the caudal is $\frac{1}{12}$. The vertical section at the occiput is nearly square, from thence the sides of the head are gradually compressed towards the truncated muzzle, the breadth of which is $\frac{1}{3}$ less than that of the occiput. The upper part of the head is flattened, gently declining to between the eyes, when it becomes arched and abruptly declining. The length of the head is $\frac{1}{4}$ of the total, the depth at occiput about $\frac{1}{3}$ of the length. The distance from the muzzle to the orbit is $\frac{1}{3}$ of the length of the head. The upper part of the orbit forms a part of the profile; the diameter of the eye is $\frac{1}{4}$ of the length of the head. The mouth is rather large: as the jaws are truncated in front, they consist of a central and two lateral portions. The central or transversal supports a single close series of minute setaceous trenchant teeth: those of the upper jaw are placed vertically; those of the lower, the shorter, horizontally. In the upper jaw their number varies from 30 to 40; in the lower from 32 to 50. The number appears to be independent of age: of two individuals measuring 5 inch. in length, one had $\frac{34}{36}$, the other $\frac{34}{36}$ incisors, while two others, about 3 inches in length, had $\frac{34}{40}$ and $\frac{30}{32}$. On each side of the lateral part of the upper jaw, a short distance behind the incisors, appears a small canine. A much longer canine, equalling the diameter of the eye, is placed on each side of the lower jaw immediately behind the incisors. When the mouth is closed each of the lower canines is received into a large oval cavity in the palate. Behind the canines the jaws are toothless. There is no tongue; under the throat are two excessively minute filaments. Just above and a little in front of the root of the pectorals appears a short crescent-shaped fissure, the opening of the gills. On the upper part of the head are several pores, of which one above the anterior part of each orbit, appears to be constant. The body appears to be naked with numerous minute pores secreting mucus. The lateral line proceeds from the posterior part of the opercle obliquely upwards to about the fifth dorsal ray, from whence it follows close to the base of the fin towards the eleventh ray, when it turns for a short distance obliquely downwards and suddenly terminates. The dorsal fin commences on a line with the posterior margin of the preopercle; the first ray is a little shorter than the rest, which are nearly equal, $\frac{1}{3}$ of the greatest diameter of the body. The dorsal, like all the other fin rays, are undivided, but the first 11 dorsal are simple, not jointed; the last one is connected by a triangular membrane to the posterior part of the back. The caudal equals the length of the head; when spread out, the posterior margin is rounded with the points of the rays exposed, but ordinarily the fin appears lanceolate. The anal commences opposite the twelfth dorsal ray; it resembles the dorsal, but the rays are a little shorter; the last one is connected by a membrane to the posterior part of the abdomen. The pectorals are rounded, $\frac{1}{5}$ of the total length. The ventrals consist of three rays, of which the anterior is the shortest; the central is the broadest, but its length equals the very thin posterior one, which is about $\frac{1}{8}$ of the total length. Single individuals occur at all seasons at Pinang. They resemble some of the *Gobioidæ* in their power of sustaining life for some time out of water, in their skipping movements, and in their habit of inflating the gill-membrane. The diaphragm is silvery white; the stomach capacious, generally expanded with minute crustacea; the liver small; the gall large, pyriform: the intestinal canal is simple, about the length of the fish; the air-vessel small, pyriform, silvery. This species is closely allied to *P. bankieri*, Richardson, which, however, is rapidly distinguishable by its larger eye ($\frac{1}{3}$ of the head) and by the third ventral ray being much shorter than the second. [*Ichthyology of the Voyage of H. M. S. Sulphur*, 136, Pl. LXIV. Fig. 8, 9.—*Report* 1845, 266.

Fam. LOPHIOIDÆ.

Genus ANTENNARIUS, (*Commerson*) *Lacepede* 1798. (Chironectes, *Chironectes*, Illiger. 1831, a genus of *Marsupialia*. *Cuvier*, 1817).

Head compressed with three free rays on the crown; mouth vertically cleft; opening of the gills small, round, behind the pectoral fins, in the posterior part of axilla. Tongue toothless. Intermaxillaries, lower jaw, vomer, palantines and pharyngeals with minute card-like teeth. Dorsal fin elongated.

(3784) *Antennarius raninus*, (Tilesius).

Syn. Klein: Miss. III Pl. 3, Fig. 4?
Lophius histrio, Var C., Bloch-Schn., 142?

Chironectes raninus, Richardson, Rep. 1845, 203.
Chironectes marmoratus, Temm. and Schl. Fauna Jap Pisc. 159, LXXXI. Fig. 1.

Ground colour of back, sides and fins yellow ochre, largely marbled with blackish brown, in which occur single darker spots; abdomen silvery yellowish-white with brown spots; the cutaneous filaments of the fins and back blackish, those of the sides pale yellow, those of the abdomen white. Iris pale brownish golden with distant radiating brown lines; pupil sinuate, black. D 3—12, C 9, A 8, V 5, P 10, Br. 7. Inhabits *Sea of Pinang*, New Guinea, Bombay, Japan. Total length 4½ inch. Yellow body is minutely granulated, and the first dorsal ray is excessively slender: it was absent in the larger of two individuals observed at Pinang.

(3785) *Antennarius hispidus*, (Bloch-Schn.)

Syn. Kochlfauter. N. C. Petrop. X. Pl. 8, Fig. 1.

Chironectes lophidus, Cuvier: Mem. du Mus. III. Pl. 17 Fig. 2.
Chironectes hispidus, Cuv. and Val. XII 407.

Pale reddish yellow (flankin colour), paler on the abdomen; head and back with transversal sooty brown stripes: those of the nape and back nearly transversal or slightly oblique, radiating obliquely downwards from the eye and from the tail; all the fins except the ventrals spotted with sooty brown; first dorsal ray yellowish alternately brown; the tuft of filaments longitudinally blackish and white; the few short filaments of the body, the lips, tongue, and cavity of the mouth pale yellowish. Iris pale burnished golden with radiating brown lines; pupil black, circular. D 3—12, C 9, A 7, V 5, P 10, Br. VI. Inhabits, *Sea of Pinang*, *Singapore*, Bay of Bengal. Total length: 9 inch. The body and fins are covered with small, closely set, dipartite spines which rise vertically from the skin. The lateral line is composed of larger somewhat distant spines, each terminating in 6 to 9 points; it commences from the muzzle, proceeds in an arch above the eye and continues following the slope of the back towards the posterior part of the second dorsal. A second, rather indistinct line of distant, larger spines is observed on the upper half of the upper jaw, and a third similar marks externally the posterior margin of the opercle. Here and there on the body, but particularly towards the anterior part of the abdomen, appear some short fleshy filaments. The larger individual was observed at Singapore in May 1840, a second, 4 inches in length, at Pinang in 1845 The stomach is conical, very capacious, occupying the entire length of lower part of the expansible abdominal cavity; the coats are very thick, leathery; the internal surface with numerous irregular folds. The duodenum, the widest of the intestines, receives the elongated ductus coledochus at a distance of about $\frac{3}{8}$ inches from pylorus. The length of the intestinal canal is double that of the fish. The liver is very voluminous, elongated; the gall bladder is like a pea, half imbedded in the liver; the spleen very minute. The air-vessel large, oval; the coats very thick.

(3786) *Antennarius commersoni*, (Lacepede).

Lophius commersonii, Lacepede I. 327.
Lacepede I. Pl. 14, Fig. 3?
Chironectes commersonii, Cuv: Mem. du Mus. III. 435, Pl. 18, Fig. 1.
Chironectes commersonii, Cuv. and Val XII. 426.

Bluish black. On the back, above the lateral line, and in front of the first articulated ray an oblique rose-coloured oval spot, within which a black ring; at the root of the caudal, above and below two similar smaller spots, and one on the side between the pectorals and anal fins. First very slender dorsal ray alternately rose-coloured and black, the tuft of filaments rather full, blackish grey. Rays of the dorsal, anal, pectoral and ventral fins black, the membranes inky with a rather broad submarginal rose-coloured band, edged with black. The points of the ventral rays rose-coloured. The caudal rays black; between the third and ninth, near the root, the black membrane has a transversal rose-coloured band divided in the middle by a black line. On the posterior part of the caudal a broad sub-marginal rose-coloured band, within which four somewhat undulating black lines, edged with black. Lips throat, tongue, and cavity of the mouth light bluish gray, dotted with black. Iris rose-coloured silvery, with six radiating black lines, pupil circular, black. D 3—14, C 9, A 7, V 5, P 9, Br. VI.? Inhabits *Sea of Singapore*, Isle of France. Total length: $5\frac{7}{8}$. The body and fins are covered with small black spines like those of *A. hispidus*, but there are no fleshy filaments. The lateral line is continued to the root of the caudal fin. The abdomen is very expansible. The present differs from the description given by Cuvier and Valenciennes in the position and number of the rose-coloured spots or ocelli, and the anal fin has one ray less, differences sufficiently insignificant to be considered individual. A single individual was observed at Singapore in May 1840.

Genus BATRACHUS, *Klein* 1744. Head broad; mouth widely cleft, lips frequently with numerous cutaneous filaments; anterior dorsal fin very small and almost hid by the integuments; pectorals supported by flat short arms; ventrals jugular with three rays of which the anterior is elongated, flattened like a sword-blade; teeth in the jaws, vomer and palate; posterior dorsal and the anal extensive, but low; sub-opercle as large as opercle, both terminating in strong spine; infra-orbitals none; branchiostegous rays six.

(3787) *Batrachus grunniens*, (Linne).

Batrachoides gangene. Buchan. Ham. 34, 365 Pl. XIV. Fig. 8.
Batrachus grunniens, Cuv. and Val. XII. 466.

Head above, back and sides light greenish or brownish olive, abdomen greenish or brownish white; head marbled and spotted with black; body with more or less distinct oblique and vertical broad bands, darker than the ground-colour

edged and spotted with black; fleshy filaments buff; fins of the ground-colour of the body, dorsals and anal indistinctly clouded with black or with very oblique blackish bands; caudal, pectorals and ventrals with blackish spots or narrow vertical bands. Iris narrow silvery olive, orbital part blackish. D 3—22, C 13½, A 18, V 1/2, P 23, Br. VI. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore,* Java, Bombay, Gangetic estuaries. Total length: 10 inch. The length of the head is about ¼ of the total; the transversal diameter of the orbit is ⅛ of the length of the head. The eyes are placed nearly horizontally, their distance from the muzzle is one diameter, from each other it is somewhat less than two transversal diameters. The intermaxillary teeth are minute, placed in a double series, which reaches from the symphysis to opposite the eyes. A double series of stronger conical teeth occupies the vomer and palatal, and extends further back than the intermaxillaries. The lower jaw has a double series of strong conical teeth on the symphysis, but it becomes single in the branches of the jaw. The tongue is bony, small, flattened, elongated and so completely hid in the integuments that it cannot be perceived during life. The opercle terminates in two strong spines of which the superior points obliquely upwards and backwards, the lower is horizontal. The sub-opercle terminates in a single horizontal spine, in length equalling the lower one of the opercle. A number of fleshy filaments terminating in cilia are scattered over the head. One behind each eye, and at the angle of the mouth is longer than the rest. The greatest vertical diameter of the body equals the length of the head. The ventral spine is very short and by a membrane closely joined to the first ray which is the longer and undivided. The second ray is shorter and divided in numerous branches. Single individuals occur, but rarely, at Pinang. The natives attribute poisonous qualities to these fishes, and reject them even as manure. The creaking sound they emit has been noted by Buchanan. They are capable of living a considerable time out of their element.

Fam. TEUTHIDID.E.

Genus TEUTHIS, *Linne* 1766. (Siganus, *Forskal* 1775.—Centrogaster. *Houttuyn.*—Amphacanthus, *Bloch-Schneider* 1801.—Buro, [*Commers.*] *Lacepede,* 1803.) Body oval, compressed; mouth slightly cleft and little protractile; teeth minute, crenulated, in a single series; a horizontal spine in front of the dorsal fin; ventrals with two spines; an external and an internal, between which three rays; branchiostegous rays five, of which the lowest is dilated and hid in the isthmus.

(3788) *Teuthis java,* Linne.

Syn. Gronov. Zoophyl. 113, No. 352, Pl. 8, Fig. 4.
Teuthis java, Linn.: Syst. 1362.
Russell CII. Werabuah.
Teuthis javus, Cuv. R. A. II. 223, (2).

Amphacanthus javus, Bleeker: Verh. Batav. Gen. XXII. 5.
Ikan kitang of the Malays.

Head above, back and sides dark brownish neutral tint, paler towards abdomen; on the head and back numerous pale bluish grey rounded spots, which on the sides and chest become elongated, irregular, vermiculated; on the abdomen longitudinal and whitish; sides of the head metallic greenish yellow or sulphur-coloured; cheeks washed with brown; pectorals transparent greyish white; rest of the fins pale brownish grey closely dotted with brown, and washed with brown, pale orange and lilac. Iris pale metallic sulphur-coloured; orbital half dark brown or neutral tint. D 13/10, C 17$\frac{10}{1}$, A 7/9, V 1/3/1, P 18, Br. V. Inhabits *Sea of Malayan Peninsula and Islands,* Sunda, Java, Madura, Coromandel. Total length. 11 inch. The length of the head is a little more than ⅛ of the total, in which the depth at occiput is contained 3⅓ times. The greatest diameter of the orbit, which is a little oblique and falling beneath the widened crenulated anterior margin, is ⅓ of the length of the head. The greatest vertical diameter of the body is 2½ in the total length. The horizontal spine in front of the first dorsal has in the young of this and of the following species the point exposed; with age it becomes entirely hid by the integuments. In young individuals the length of the head is from 4½ to 4⅔ in the total; the greatest diameter of the orbit is 2¾ in the length of the head; the greatest vertical diameter of the body is 2⅔ in the total length. At Pinang small individuals are numerous at all seasons. As all the species of the present genus are supposed by the Malays of the Straits to be highly poisonous, they are not eaten, but set aside among offal of fish to be used as manure.

(3789) *Teuthis concatenata,* (Cuv. and Val.)

Syn. Amphacanthus concatenatus, Cuv. and Val. X. 127.
Kitang of the Malays.

Head above, back and anterior part of the sides above the lateral line blue purple; rest of the sides reddish yellow; abdomen reddish white; back and sides with numerous rounded brick-red spots becoming reddish yellow on the lower part of the sides; sides of the head reddish yellow bronze washed with brown; nostrils, infraorbitals and opercles brimmed with cobalt; pectorals transparent; rest of the fins pale brownish grey, closely dotted with brown, washed with pale reddish yellow and lilac; between the dor-

sal and anal rays some indistinct brown spots. Iris narrow, sulphur-coloured round the pupil; rest brown bronze. D 13/10, C 17½, A 8/9, V 1/3/1, P 17, Br. V. Inhabits *Sea of Pinang*, Isle of Buru, Batavia. Total length: 6⅝ inch. The length of the head is 4⅓ in the total, the depth at occiput 3½. The greatest oblique diameter of the orbit is 2½ in the length of the head. The outline of the head is convex, particularly between the eyes. The greatest vertical diameter of the body is 2½ in the total length. When the caudal fin is spread out, the posterior margin is nearly straight. Single individuals occur at Pinang at all seasons.

(3790) *Teuthis dorsalis*, (Cuv. and Val.)

Syn. Amphacanthus dorsalis, Cuv. and Val. X. 143.
Amphacanthus dorsalis, Schlegel and Muller: l. c. 10, 13, Tab. 2, Fig. 1.
Kitang of the Malays.

Head above and back pale brownish olive, lighter on the upper half of the sides; lower half and abdomen bluish white; immediately beneath the origin of the lateral line and in front of the pectorals pale reddish lilac; back and sides with numerous small oval bluish white spots; cheeks and opercles pale metallic sulphur-coloured; opercles edged with pale lilac; pectorals transparent; caudal pale brownish olive, minutely dotted with brown; rest of the fins greyish white, tinged with lilac, minutely dotted with brown. Iris yellowish white, orbital margin olive. D 13/10, C 17½, A 7/9, V 1/3/1, P 16, Br. V. Inhabits. *Sea of Pinang*, Batavia. Total length: 6 inch. The length of the head is 4⅓ in the total. The greatest, oblique, diameter of the orbit is ⅓ of the length of the head. The greatest vertical diameter of the body is ½ of the total length. At Pinang this species is numerous at all seasons.

Genus ACANTHURUS, *Forskal* 1775. (Harpurus, *Forster* 1778.—Aspidurus, *Lacep.* 1802.) Tail on each side armed with a strong moveable spine; head and body compressed; eyes elevated; mouth slightly cleft; teeth in a single series, trenchant, with crenulated margins; dorsal single; body covered with minute scales; branchiostegous rays five.

(3791) *Acanthurus xanthoplerus*, Cuv. and Val. Plate IV.

Syn. Acanthurus xanthopterus, Cuv. and Val. X. 215.

Young. Head and body violet brown, paler towards abdomen; the nostrils opening in a bright gamboge triangular spot, resting behind on the anterior half of the orbit, the apex towards the middle of the profile; dorsal fin bright yellow, minutely dotted with brown; along the base a cobalt blue longitudinal band, above which a second parallel lilac one terminating on the anterior third of the fin; a third and a fourth above each other: both bifurcating about the anterior half; upper margin black; anterior half of caudal white, the rest brown like the body; posterior margin broad, black; anal bright yellow minutely dotted with brown, with a cobalt blue basal band, above which four parallel lilac ones, external margin black; ventral spine and rays pale bluish black; membrane pale grey minutely dotted with brown; pectoral rays yellow, membrane transparent. Iris narrow, yellow round the pupil, next broad silvery white, orbital margin reddish brown. D 9/27, C 17½, A 3/25, V 1/5, P 17, Br. V. Inhabits *Sea of Pinang*, Seychelles. Total length: 5⅛ inch. The length of the head is 4½ in the total; the diameter of the eye is 3½ in the length of the head. The preopercle, opercle, scapular and humeral bones are distinctly radiated. In each jaw is a single series of 16 trenchant teeth: those of the upper appear somewhat larger and their margin has from 10 to 12 crenulations (Fig. 3. Magnif.); in the lower jaw the pair of teeth on the symphysis is longer than the rest, and the whole of the margin carries 10 crenulations: all the rest are shorter, truncated with about 5 crenulations. The greatest vertical diameter of the body (Fig. 2.) is 2½ in the total length. The whole of the head and body, the anterior half of the caudal and the base of the dorsal and anal fins, are covered with small elongated oval scales (Fig. 4. Magnif.), of which those of the body have the posterior part truncated with about 12 unequal cilia on the margin. The lateral line appears like a thread at the upper fifth of the body; it is slightly undulating, following the outline of the back, which is less arched than that of the abdomen, till it arrives between the terminations of the dorsal and anal fins. From thence it is at first a little downwards arched and then rises, so as to pass above the spine of the tail towards the caudal. Above and below the lateral line appear a number of short, excessively minute, backwards directed tubes. The length of the spine is less than the diameter of the eye; the anterior margin is sharp, the posterior rounded. The posterior margin of the caudal is slightly concave; the superior lobe a little longer than the inferior. The stomach is short, thick, gizzard-like; the gall very large. There are four cœcopyloric appendages. The intestinal canal is spirally folded, more than twice the length of the fish. A single young individual was observed at Pinang in March 1845. The fishermen asserted that it is of rare occurrence, and attains to a foot in length.

Fam. AULOSTOMATIDÆ.

Genus CANNORYNCHUS, *Cantor*. [Κάννη, reed; ῥύγχος, snout. Substituted for *Fistularia*, Linne, 1766, pre-occupied by *Fistularia*, Donati,

1750. (*Polypi*).] (*Equivalent to* Fistulari. *Linn.* 1766). Mouth tubular, elongated, depressed; jaws slightly cleft, nearly horizontal, with small teeth; head elongated from ⅓ to ¼ of the total length; body elongated depressed; scales invisible; behind the head, above and below, some bony appendages cover the anterior part of the head, dorsal fin single, and as well as the anal composed of undivided rays; branchiostegous rays seven.

Fistularia immaculata, Richardson, Rep. 1845, 247.

Young. Head above light greenish grey; upper half of opercles greenish olive minutely dotted with black, lower half as well as the under surface of the head and the abdomen whitish; sides of the body light slate grey; the lateral line bordered beneath by a pale silvery bluish white line; fins greenish hyaline; caudal filament brownish olive. Iris narrow golden round the pupil; the rest blackish silvery. D 15, 16 or 17 C 13/5, A 14 or 15, V 1/5, P 15, Br. VII Inhabits *Sea of Pinang*, Indian Ocean, Coromandel, Mohila, (Red Sea.)

Length of the head,...	... ...	... 0 ft. 5½ inch
„ „ „ body to the root of caudal fin,		... 0 „ 8⅞ „
„ „ „ caudal filament,	...	... 0 „ 4⅝ „
Total length,.....		1 ft. 6⅜ inch.

The length of the head is ⅓ of the length of the body, measured from the symphysis of the lower jaw to the point of the caudal fin. The tubular mouth, to the anterior margin of the orbit, is 2¾ times longer than the rest of the head. The horizontal diameter of the eye is 9½ in the length of the head; the distance of the eyes across the forehead is ½ of the diameter; the narrow forehead is widened by a transparent membrane extending along the upper margin of the orbit, and giving it an elongated oval shape. From the sides of the occiput proceeds a sharp crest of minute spines to the præopercle; the posterior and anterior part of the orbit are finely toothed, and the latter part has a short broad spine above and below. On each side of the tubular mouth, appears a sharp ridge, the posterior half of which is armed with small forwards directed spines. The lower jaw is longer than the upper, with a round protuberance at the symphysis. Both jaws have a single series of small, somewhat unequal, reclining teeth. A similar single series appears on each of the palatals, and from four to six on the anterior part of the vomer. Between the intermaxillary series of teeth and those of the vomer is extended small crescent-shaped membrane. From the centre of the opercle proceed downwards two strong striæ and numerous finer ones radiate backwards. From the posterior part of the orbit radiate a number of lines backwards. Immediately behind the occiput commence a pair of elongated lanceolate bony plates, each contained about 5½ times in the length of the body, forming in the middle of the back a slightly raised line. Behind the pectoral fins appears a shorter lanceolate bony plate, the upper margin of which joins the former pair of the back; the lower joins a larger also lanceolate plate, which on each side covers the anterior part of the abdomen. The latter pair of abdominal plates are turned up at the sides at a right angle; their lower surface is honeycombed and the anterior half of their lower margin leaves a central open space on the abdominal surface. The length of the pair of abdominal plates is ⅔ of the dorsal. The length of the pectoral fins and the lobes of the caudal equal the horizontal diameter of the eye. The vertical diameter at occiput, as well as the greatest diameter of the body, is ⅘ of the horizontal diameter of the eye. The breadth across the occiput equals the latter diameter. A vertical section of the head is broad rectangular; one of the anterior part of the body, in front of the dorsal, is nearly triangular; behind the dorsal it is rhombic. The dorsal and anal fins commence opposite each other at the posterior fourth of the distance from the anterior part of the orbit to the point of the caudal lobes. The lateral line commences above the opercle; the anterior part, occupying the dorsal plates, is arched with the convexity towards the centre of the back, so that the lines of both sides describe the figure of an elongated hour-glass. At the termination of the lateral pair of bony plates the lateral line commences, following the centre of the side, above the bluish white line. The lateral line consists of a number of linear tubes, deeply cleft at both ends; behind the dorsal fin the tubes change to very short, sharp bony ridges, which to the touch appear like spines. The ventral fins are very short situated in the centre between the muzzle and the point of the caudal lobes. The length of the elongated central caudal ray appears to be proportionally longer in the very young individuals; in the largest it was divided in two. Four individuals were observed at different seasons at Pinang; [Another species of the present family: *Amphisyle soulata*, Klein, was observed in great numbers at Singapore in May 1840. From 1842 to 1845 none occurred at Pinang, nor were the fishermen there acquainted with the fish.] they were examined sometime after death, and none of them exhibited the lateral series of blue spots noted by Dr. Ruppell.

ORDER ANACANTHINI. Fam. PLEURONECTIDÆ.

Genus PLATESSA. *Cuvier*, 1817. In each jaw a series of trenchant obtuse teeth; frequently on the pharyngeals teeth like paving-stones; dorsal extending in front to above the upper eye, leaving, as well as the anal, a naked interval between themselves and the caudal; shape rhomboidal; most species have the eyes on the right side; [The terms *right and left*, or *dextral* and *sinistral* are applied to the species of this family, as to those of every other, while the fish is placed with the tail towards the observer, the dorsal fin upwards, and the anal downwards.] two or three small cœca.

Eyes and colour on the left side.

(3793) *Platessa russelli.*

(*Icon.*) Platessa russelli, Gray: Ill. Ind. Zool. Pl. 94. Fig. 2.
Ikan Siblah of the Malays.

Left side. Pale reddish or yellowish-brown; each scale with a vertical buff spot close to the dark brown posterior margin; opercle and anterior third of abdomen pale bluish or neutral tint. Iris silvery, coloured like the body. *Right side.* Buff or dust-coloured; opercle and anterior third of abdomen pale bluish. Fins transparent, coloured like the body, but paler, minutely dotted with brown; dorsal, caudal and anal with a few scattered indistinct brownish spots. D 70 to 73. C 15½. A 56, V 6, P 12, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore.* Total length: 1 ft. 1 inch. *Left side* The length of the head is 4⅓ in the total. The upper orbit occupies the second-fourth of the head, close to the profile of the back without encroaching upon it; it is oval; the horizontal diameter being ¼ of the length of the head, exceeds by ⅓ that of the lower rounded orbit. Both are separated by a very narrow sharp ridge. The vertical distance from the centre of the inferior orbital margin of the lower eye to the margin of the lower jaw is ⅓ of the length of the head. The posterior apertures of both nostrils are situated immediately in front of the orbits; they are rounded and larger than the anterior ones. Of the latter the upper one appears to be a small puncture about mid-way in front between both orbits. The lower anterior aperture is situated obliquely in front of the posterior, close to the margin of the left upper maxillary. The latter bone is narrow, widened and obliquely truncated at the lower extremity. The angle of the mouth scarcely extends to the anterior part of the orbits. The margin of the mouth is exclusively formed by the elongated intermaxillaries, to which are confined the teeth. The latter are conical, blunt, slightly inwards arched and placed in a single series, of which the anterior four or five of each side are a little larger and more distant than the rest, which are minute and placed closely together. The teeth of the lower jaw are longer, fewer, and all with intervals. The tongue is linear, smooth. The opercles and cheeks are hid by scales. The form of the body is oblong, the greatest vertical diameter, at the second-third of the total length, slightly exceeds ⅓ of the total The body is covered by upwards of 67 longitudinal series of scales, of which there are about 81 on a line between the gill-opening and the caudal. The scales are small rounded with about 15 radiating lines at the radical part; the posterior margin is closely ciliated. The lateral line consists of simple tubes It commences at the lower margin of the lower orbit, ascends in the shape of the letter S to the upper extremity of the preopercle, then slightly descends to above the posterior angle of the opercle, when it suddenly rises describing a short arch, terminating above the point of the pectorals. From thence it proceeds straight along the middle of the side to the point of the posterior margin of the caudal fin. The dorsal fin commences opposite the anterior angle of the upper orbit; the distance from the muzzle equals the horizontal diameter of the upper eye. All the rays, except the three last ones, are undivided, and with a single series of small scales along the anterior margin; the point of the rays project a little beyond the membrane, so as to give the fin a fringed appearance. The longest rays are contained 2¼ times in the length of the head: they are situated at the commencement of the posterior half of the fin, the distance of which from the caudal is ⅓ of that of the anterior ray from the muzzle. The root of the caudal is covered with small scales; the posterior margin is pointed in the centre, the two rays of which are the longest, ⅔ of the head. The posterior four or five anal rays are divided; the rest are simple and resemble the dorsal. The extent of the base of the anal is about ¼ less than that of the dorsal. The left ventral is situated a little nearer the gill-opening than the anal; the two first rays are undivided; the second, the longest, is ⅔ of the head, and extends to the second anal ray. The right ventrals is a little farther back, the first ray commencing opposite the third ray of the left fin. The two upper pectoral rays are undivided; the third, the longest, slightly exceed ⅔ of the head. Single individauls occur at Pinang, at all seasons. They are eaten by the natives.

Genus HIPPOGLOSSUS, *Cuvier*, 1817. Fins resembling those of *Platessa*: form generally more elongated; jaws and pharynx with teeth, in most species strong and sharp.

A.—Eyes and colour on the right side.

(3794) *Hippoglossus erumei.* (Bloch-Schneider.)

Syn. Pleuronectes erumei, Bloch-Schneider.
Russell, LXIX. Adalah.
Hippoglossus erumei. Cuv. R. A. II. 340. (2)

Hippoglossus erumei, Ruppell: Atlas 121.
Hippoglossus erumei. Ruppell: Neue Wirbelth, Fische, 84.
Ikan Siblah of the Malays.

Right side. Dull brownish or greenish-grey; anterior third of dorsal milk-white, minutely dotted with brown; rest pale bluish brown, dotted with brown and washed with black; caudal blackish with a broad vertical, whitish band at the base; anterior eighth of anal milk-white, rest like dorsal; pectorals and ventrals hyaline, the latter minutely dotted with brown. Iris silvery, sending a number of vermicular diverging threads over the circular black pupil. *Left side.* Brownish white, minutely dotted with brown. D 48 to 53, C 15/5, A 35 to 39, V 6, P 14 or 15, Br. VII. Inhabits *Sea of Pinang, Malayan Peninsula*, Coromandel, Bay of Bengal, Estuaries of the Ganges, Massauah. Total length: 1 ft. *Right side.* The length of the head is ¼ of the total. The upper orbit is placed horizontally on the upper surface of the head; its distances from the muzzle is ⅔ of its longitudinal diameter, which is ¼ of the length of the head. A little below, and in front of the upper orbit, on the left side of the muzzle, appears the posterior circular aperture of the left nostril: the anterior one is smaller, tubular and situated a little in front of the posterior. The right orbit is slightly shorter than the left, and is situated vertically on the left side of the head, bordering upon the upper maxillary. The circular pupils are protected by a number of vermicular silvery filaments which diverge from the upper margin of the iris. The distance between both orbits scarcely exceed ¼ of their diameter; each orbital margin is a little raised with a narrow intervening furrow. The apertures of the right nostril are situated immediately in front of the right eye, and resemble the corresponding of the left. The upper maxillary is elongated, widened and truncated bowel. The linear elongated intermaxillaries form the margin of the mouth, and have two series of long, distant, arched teeth, each with a minute barb on the posterior part of the point. The teeth of the external series are fixed, but those of the internal are moveable, and may be laid down like those of *Saurus nehereus*, (Buchan. Hamilton). The teeth of the lower jaw resemble those of the upper, but they are more numerous; those of the inner series are a little longer, and those near the symphysis have an indistinct double barb. On each side of the palate appears a single series of small pointed teeth, and in young individuals, upwards of 4 inches in length, four to six similar on the vomer, which, however, very early disappear. The tongue is minute and smooth; on each side of the root rises a small cluster of minute pointed teeth, and similar appear at intervals on the rest of the hyoid. The angle of the mouth is situated opposite the posterior part of the left orbit. The greatest vertical diameter of the body, at the second third of the total length, slightly exceeds ½ of the latter. The lateral line commences at the inferior margin of the lower eye, which it follows, and turning backwards over the upper margin of the opercle, it describes a low arch which terminates opposite the middle of the dorsal. From thence it proceeds straight along the middle, to the point of the posterior margin of the caudal. The line is a little raised, and is on each scale composed of three small tubes: a central, from which an upper and lower diverge backwards. The greatest vertical diameter contains from 55 to 57 series of scales; the lateral line, from the opercle to the root of the caudal, 69 to 71 scales. The scales are small rounded, with 12 to 15 radiating lines at the radical portion and indistinctly ciliated in the centre of the posterior margin. The dorsal fin commences behind the upper orbit at a distance of one longitudinal diameter, and terminates at an equal distance from the caudal. The 9 or 10 anterior rays are undivided; the longest, towards the middle of the fin, are 2½ in the length of the head; all have at their anterior margin a series of small scales. The anal is ⅛ shorter than the dorsal; the two first rays are undivided; in other respects it resembles the dorsal. The root of the caudal is scaly; the posterior margin is bluntly pointed in the centre, the two rays of which, the longest are ⅔ of the head. The right ventral is situated a little in front of the pectoral, much nearer the gill-opening than the first anal ray; the two first rays are undivided; the fourth, the longest, is 2½ in the length of the head. The left ventral is placed a little farther backward. The pectorals are pointed, ⅓ the length of the head. The stomach is very capacious, broad pyriform; the intestinal canal is simple, about ¼ of the total length. Single individuals occur at all seasons at Pinang, and are eaten by the natives.

B.—Eyes and colour on the left side.

(3795) *Hippoglossus erumei*, Var. A. Inhabits *Sea of Pinang.* This is simply a *reversed, sinistral variety*, necessary, however, to distinguish as such from a second, differing in colours. The present attains to the size of the dextral, but at Pinang it is of rarer occurrence. Individuals of equal length differ in no characters except in such as are necessarily the consequence of *reversion*, such, for instance, as the left ventral fin being placed a little anterior to the right.

(3796) *Hippoglossus erumei*, Var. B.

Syn. Russell, LXXVII. Neoora-Nalaka C.
Hippoglossus nalaka, Cuvier, R. A. II. 340 (?).

Left side. Ground colour pale brownish grey or white minutely dotted with brown; a broad brownish black vertical band, extending from the jaws over the sides of the head and body to the

root of the pectorals; two similar on the sides of the body, and a fourth over the posterior part of the body and the tail; and three last bands extending faintly over the corresponding parts of the dorsal and anal; anterior half of caudal whitish dotted with brown; posterior half brownish black; rest of the fins and eyes like *H. erumei*. *Right side*, like the *left* of *H. erumei*. Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Singapore*, Coromandel. Except in colours and being sinistral, the present variety agrees in every other character with *H. erumei*. Russell, indeed, obseved the strong resemblance, but he imagined that in this variety the scales were smaller, and the lateral line carinated. Comparison of equal individuals of both shews no difference of the size of the scales, and the lateral line is equally raised in both. Russell describes the length as being six inches. Of a number of individuals examined at Pinang and Singapore none exceeded 6⅔ inches. It remains to be ascertained if this variety attains to the same size as *Var. A*, or if it is merely a transient livery of certain young individuals of *Var. A*.

Genus SOLEA, *Klein* 1748. Eyes and colour on the right side; mouth distorted on the side opposite the eyes; minute crowded teeth in the half of both jaws opposite the eyes, the other half toothless; form of the body oblong; muzzle rounded and generally projecting beyond the mouth; dorsal commencing opposite or a little in front of the upper eye; caudal separated from dorsal and anal.

(3797) *Solea humilis*, Cantor. *Right side*. Pale umber-brown, minutely dotted with black, and with numerous small blackish spots; an indistinct larger one close below the middle of the base of the dorsal, and a second at the posterior third; two corresponding spots near the base of the anal; membranes of the fins pale brownish buff dotted with black, rays pale umber; on the caudal some indistinct blackish spots; near the point of the pectoral an oval, and between the two lowest rays a linear black spot. Iris pale silvery. *Left side*. Pectoral, ventral and short filaments about the mouth brownish white, D 57, C 12⅘, A 42, V 5, P 8, Br. VI. Inhabits *Sea of Pinang*. Total length: 3⅘ inch. *Right side*. The form of the body resembles that of *Solea pegusa*. Yarrel, [Zool Journ. IV. 467, Pl. 16,—British Fishes: II. 260] but the vertical diameter is greater in the present. The length of the head is 5⅓ in the total. The upper orbit, the larger, is situated in the centre between the angle of the mouth and the corresponding part of the dorsal, but much nearer the muzzle; the horizontal diameter is ⅛ of the length of the head. The lower orbit is situated between the angle of the mouth and the posterior angle of the upper orbit, of which its horizontal diameter is ⅓. The distance between the orbits slightly exceeds the horizontal diameter of the upper orbit. The whole of the head is covered with little scales like those of the body rough to the touch. The tongue is minute, smooth, truncated triangular. The greatest vertical diameter of the body, at the end of the anterior third of the dorsal, is 2½ in the total length. On the diameter may be counted 69 series of scales. The slightly raised lateral line continues straight from behind the upper part of the opercle to the caudal, a little nearer the back than the abdomen. It contains 85 scales, each with a minute central tube. The scales of the head and body are small, elongated tetragonal, the posterior margin rounded. On the radical part appear about nine radiating lines, some of which are divided in two; the centre of the posterior margin has upwards of thirteen cilia, although very fine, yet sufficiently strong to make the scales appear rough to the touch. The fist dorsal ray commences on a level with the anterior angle of the upper orbit. The first nine rays are undivided; all are covered by an elongated pyramidal sheath of scales, consisting of two or three series, which extend to near the points of the rays, which project beyond the membrane. The longest rays, towards the middle of the fin, equal ½ the length of the head. The anal resembles the dorsal, but has only the four anterior rays undivided. The caudal is rounded, equal the length of the head. The pectoral is pointed, ½ the length of the head. The right ventral is very small, about ⅓ of the pectoral, and the last ray is connected by a membrane to the first anal. *Left side*. A little above and behind the symphysis of the upper jaw appears a small tubercle, through which is pierced a single minute nostril. The base of the dorsal as far as the nine first rays carries a few short soft filaments, some of which are scattered over the side of the head; they become more numerous and crowded towards the left angle of the mouth. This side of the jaws resembles the cipher 3, there being at the angle a small pointed tubercle, directed inward. The teeth are very fine, crowded and hid to the point in the fleshy lips. The left ventral is longer than the right and not joined to the anal. A single individual was observed at Pinang in October 1842.

(3798) *Solea ovata*, Richardson.

Syn. Solea ovata, Richardson: Report, 1845, 279.

Right side. Brownish ash-grey, minutely mottled with pale blackish, towards the base of the dorsal and anal three rounded, distant, black spots, edged with light grey; on the rest of the body a few scattered similar spots, also indistinctly ocellated; pectoral greyish at the base rest black; rest of the fins pale ash-grey minutely mottled with blackish. Pupil horizontally oval; iris pale silvery round the pupil; the rest ash-grey. *Left side*. Brownish white; opercles

and abdomen lead grey; filaments about the head white; fins buff. D 65, C 12½, A 48, V 5, P 9, Br. VI. Inhabits *Sea of Pinang*, China Seas, Canton. Total length: 3⅞ inch. *Right side.* The length of the head is ⅕ of the total. Both eyes are nearly equal, ⅛ of the length of the head; the upper one occupies the second-fifth; the lower is removed slightly farther back, and touches the upper lip; the posterior angle of both eyes are situated a little farther back than the angle of the mouth, the eyes are separated by a sharp rest, the diameter of which is scarcely ¼ of the horizontal diameter of each eye. The tongue and teeth resemble those organs of *S. humilis.* The greatest vertical diameter of the body, at about the middle of the dorsal is 2⅓ in the total length. On the diameter may be counted about 76 scales. The latter are rough to the touch; on the radical part appear upwards of 16 radiating lines, some of which are divided in two; the centre of the posterior margin is armed with from 9 to 12 fine spines. The lateral line proceeds straight in the middle of the side from the gill-opening to the caudal: it contains upwards of 95 scales, each with a minute central tube. The first dorsal ray commences opposite the anterior angle of the upper eye; the longest rays, towards the middle of the fin slightly exceed ½ of the length of the head. The anal resembles the dorsal. The rounded caudal is distinct, but united by a membrane to the dorsal and anal; its length is ⅕ of the head. The pectoral is elongated ⅝ of the length of the head. The ventrals are nearly equal, about ½ of the length of the head. *Left side.* Numerous filaments appear on the lower lip and the lower margin of the gill-cover. The left pectoral is but ⅓ of the right. Single individuals occur at Pinang at all seasons.

Sub Genus SYNAPTURA, *Cantor.* [Συναπτὸς, joined; οὐρὰ, tail. Substituted for *Brachirus*, properly written: *Brachyurus*, Swainson 1839, preoccupied by *Brachyurus*, Fischer, 1814. (*Mammalia.*)] (Brachyurus, *Swainson*, 1839.) General structure of *Solea*, but the caudal, dorsal and anal fins are all united.

(3799) *Synaptura commersoniana*, (Lacepede.)

Syn. Plenronecte commersonien. Lacep. III. Pl. 12. Fig. 2, (not IV. 656.)
Russell, LXX. Jerree Potoo A.
Solea commersoniana, Cuvier, R. A. II. 343. (1).
Brachirus commersonii, Swainson, II. 303.
Ikan ledah [*Ledah*, tongue,] of the Malays.

Right side. Greenish or brownish olive, darkest on the opercles, minutely dotted with brown; all the scales with a small verticle buff spot behind the cilia, giving a dusky appearance to the ground colour; pectoral black with buff margin; rest of the fins like the body but lighter; dorsal, caudal and anal with a narrow milkwhite edge within which a second sooty brown, composed by a series of single spots on the membranes; lips and pointed papillæ of the lower olive; mouth and opercles inside pale olive, closely dotted with black. Iris a silvery or golden green ring; the rest bluish black. *Left side.* Pectoral and ventral buff.

D 78 or 81.
C 12,..... *Right* V 5, *Left* V 4, P 6, Br. VI.
A 65 or 66,

155 or 159

Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Coromandel. Total length: 8⅝ inch. *Right side.* The length of the head is ⅐ of the total. The upper orbit is situated above the middle of the right upper lip at equal distance from the angle of the mouth and the muzzle; the greatest diameter is oblique, upwards and backwards is ⅛ of the length of the head. From the anterior angle of the upper orbit proceeds a short bony ridge which terminates close to the muzzle in a flat rounded point, with which the muzzle produces a short furrow. The lower orbit is situated immediately above the angle of the mouth, a little posterior to the upper one, and in a different position. The greatest diameter is oblique, downwards and backwards, scarcely shorter than that of the upper orbit. The distance between the anterior angles of both orbits equals their greatest diameter. The posterior aperture of the nostril is a little in front of the lower orbit; the anterior is a little farther in front, tubular or pierced through a small papilla. The lower right lip is fleshy with numerous pointed papillæ. The tongue is minute, linear, smooth. The teeth resembles those of *Solea humilis.* All the scales of the head, below the level of the upper eye are a little larger than those of the body; above that level, towards the origin of the lateral line, they are nearly double the size, and by far the greatest of all. The form of all is nearly rectangular, with the posterior margin rounded, with 8 or 9 fine spines, which makes the scales rough to the touch. At the radical part appear 3 or 4 radiating lines. The greatest vertical diameter of the body, at the commencement of the second third of the back, is ¼ of the total length. This diameter contains about 71 series of scales. The lateral line commences behind the upper part of the opercle and proceeds straight, a little nearer the back than the abdomen, to the caudal. It consists of about 167 minute central tubes. The first dorsal ray commences close to the muzzle, a little below the level of the anterior margin of the upper orbit. The rays, of which the first four are undivided, gradually increase in length to the last which is ⅓ of the length of the head. The caudal is elongated, terminating in a rounded point, ⅘ of the length of the head. The anal, all the rays of

which are divided, commences beneath the posterior part of the inter-opercle, between the two ventrals. The basal half of all three vertical fins are covered with minute scales, and the points of the rays project a little beyond the membrane. They are so closely connected, that the milkwhite outer margin is uninterrupted, and the shape of the fish resembles a broad point of a lance. The length of the pectorals is $\frac{1}{6}$ of the head. The ventrals are situated immediately in front of the anal, but on a little higher level; their length equals the pectorals. On the left side about the lower lip and the throat appear a number of short white filaments. The figure of Russell (LXX). is incorrect. The short arch above the upper eye is not produced by the lateral line, but by a bony ridge, and the caudal fin is too short and rounded, and distinct. His original was probably mutilated. Single individuals are of rather rare occurrence at Pinang.

(3800) *Synaptura zebra*, (Bloch).

Brachirus zebra, Swainson, II. 303.

Right side. Ground colour of head, body, dorsal, and anal ventral fins reddish white minutely dotted with brown; on the head and body upwards of 19 vertical sooty- or blackish-brown bands extending over the dorsal and anal; the bands double or in pairs, frequently confluent towards the tail; a reddish yellow or pale orange band over the root of the caudal and the last dorsal and anal rays; rest of the caudal black with several oval milk white spots; pectoral black; pupil iridescent, circular; iris pale golden, with four radiating blackish bars. *Left side.* Pectoral, ventral and filaments of the mouth and throat reddish white; opercle and abdomen bluish.

D 81 or 83.
C 16,.....*Right* V 5, *Left* V 4, P 7 or 8, Br. VI.
A 67 or 65

164

Inhabits *Sea of Malayan, Peninsula and Islands*, Chusan, Macao, Bay of Bengal, Sumatra. Total length: 7 inch. *Right side.* The length of the head is $\frac{1}{4}$ of the total. The upper orbit is situated above the middle of the upper right lip, at equal distance from the muzzle and the angle of the mouth; the horizontal diameter is $\frac{1}{3}$ of the length of the head. The lower orbit is a little farther backwards, immediately above and behind the angle of the mouth: the horizontal diameter equals that of the upper; the distance between both is somewhat less. A slight downwards arched ridge proceeds from the anterior angle of the upper orbit to the muzzle. The nostrils, mouth and teeth resembles those of *S. commersoniana*, but the lower right lip presents no papillæ. The greatest vertical diameter, at the end of the anterior third of the body, is $3\frac{1}{3}$ in the total length; it contains upwards of 71 series of scales. The latter are all small, nearly rectangular, with 7 to 9 radiating lines at the radical part, and with as many spines at the posterior rounded margin. The lateral line in its course resembles that of *S. commersoniana*; it consists of upwards of 121 small central tubes. The dorsal commences opposite the anterior angle of the upper orbit, at a distance from the upper lip of $\frac{1}{3}$ of the length of the head, but not immediately from the upper lip, as represented by Bloch, and the copies of his incorrect figure. The anterior 26 to 28 rays are undivided; the last rays are the longest as well as the caudal and the last anal rays slightly exceed the length of the head. The caudal is broader and more rounded than in *S. commersoniana*, which in other respects the three united fins resemble. The pectoral is very pointed owing to the second upper ray being much longer than the rest, although it is but $2\frac{1}{3}$ in length of the head. The length of the ventrals is about $\frac{1}{4}$ of the length of head; they are placed as in *S. commersoniana*, but the distance from the first anal ray is a little greater. Single individuals occur at Pinang at all seasons.

Genus ACHIRUS, *Lacepede*, 1802. Resembling *Solea*, but destitute of pectoral fins; dorsal and anal distinct from caudal; eyes and colours on the right side.

(3801) *Achirus pavoninus*, Lacepede.

Syn. Achire provonine, Lacepede, IV. 660.
Pleuronectes pavoninus Shaw, IV. 310.

Right side. Ground colour of head, body and fins yellowish or pink-brown; the fin-membranes dotted with black; scales edged with dark brown; head and body with numerous larger and smaller rounded milkwhite spots, edged and minutely dotted with dark brown, and with a round soot-coloured spot in the centre; a few of the white spots confluent; base of dorsal and caudal with a series of spots like those of the body; the rest of these fins, the right ventral and the caudal with numerous smaller spots destitute of the brown central spot. Iris annular, golden; rest brownish. *Left side.* Head and body brownish white or buff; opercle and abdomen pale bluish; filaments of the head white. D 67, C $12\frac{3}{11}$, A 50, V 5, P 0, Br. *right* VI; *left* V? Inhabits *Sea of Pinang*. Total length: $7\frac{1}{3}$ inch. The length of the head is $6\frac{1}{3}$ in the total. The upper orbit is situated at the upper third of the head, at equal distance from the muzzle and the angle of the mouth; the horizontal diameter is $\frac{1}{4}$ of the length of the head. The lower orbit is situated vertically below the upper, at a distance of $1\frac{1}{2}$ diameter immediately above and behind the angle of the

mouth; it is a little larger than the upper orbit. Between the anterior angles of both appears like a pore the posterior aperture of the nostril; the anterior one is tubular, pierced through a small tubercle which is situated lower down, immediately above the centre of the upper lip. The jaws are equal; the mouth very little distorted to the left; the lips are fleshy. The right side is toothless, but on the left appear numerous, minute, setaceous teeth, so completely hid by the lips, that during life they easily escape observation. On the left side of the head and on the throat appear numerous small filaments. The tongue is minute, smooth, truncated triangular. The body forms a regular elongated oval; its greatest vertical diameter is a little less than $\frac{1}{3}$ of the total length; this diameter contains about 67 series of scales. The latter are small, oval. On the posterior margin appear some spines so excessively minute, that the surface does not appear rough to the touch. The rest of the circumference of the scales is divided by upwards of 55 backwards radiating lines. The lateral line commences from the upper margin of the opercle; at first it slightly descends, and then continues in the middle of the side to the caudal; it contains about 99 central tubes. The dorsal commences very close to the upper lip, opposite the centre of the distance between the eyes; all the rays divided; the anterior and posterior ones are a little shorter than the rest, which are about $2\frac{1}{2}$ in the length of the head. The anal resembles the dorsal, but the rays are a little longer. Both fins have their basal third covered with scales. Immediately above the latter scales, on both sides of the fins, in the centre between each pair of rays, appears a very distinct rounded aperture, the margin of which is a little raised, and the bottom of which is formed by a lamina of the fin membrane. From the upper part of each aperture proceeds a linear fold, which may be traced to the external margin of the fins. Commerson discovered a similar row of pores along the base of the dorsal and anal rays of *Achirus marmoratus*, Lacepede; [Lacepede, IV. 660.—*Pleuronectes marmoratus*, Shaw, IV. 310.] and later, Dr. Ruppell observed similar in *Achirus barbatus*, Geoffroy. [Ann. du Mus, I. Pl. XI.—Ruppell: Atlas, 122. Tab. 31, Fig. 2.] The caudal is scaly, rounded, $\frac{3}{4}$ of the length of the head. The right ventral is broad, rounded; all the rays are divided, $\frac{3}{4}$ of the length of the head; the fifth ray is throughout connected by a membrane to the first anal. The left ventral commences a little more backward; it is narrower and shorter, and not joined to the anal. A single individual was observed at Pinang in August 1843.

Genus PLAGUSIA, *Brown*, 1756. Dorsal, caudal and anal fins united; otherwise resembling *Achirus*. *Eyes and colour on the left side.*

(3802) *Plagusia Bilineata*, (Bloch.)

Ikan ledah of the Malays.

Left side. Pale reddish brown; scales with metallic iridescent reflections, with a pale dark brown longitudinal line, and with a buff or whitish vertical line along the root of the fine spines: opercle bluish or neutral tint; fin-membranes hyaline; rays buff. Iris narrow golden round the circular pupil; rest blackish blue. *Right side.* Brownish white; opercle and abdominal cavity bluish.

D 96 or 97,
C 8 .....*left* V 5, *right* V 4, P 0, Br. VI.
A 70 or 73,

174 or 178.

Inhabits *Sea of Malayan Peninsula and Islands*, Coromandel, Bay of Bengal, Red Sea, Sumatra, Java, Madura. Total length: 9 inch. *Left side.* The form of this as of all the following species is elongated lanceolate. The length of the head is $4\frac{1}{3}$ in the total. The muzzle bluntly pointed; the distance to the anterior angle of the upper orbit is $10\frac{1}{2}$ in the total length; the muzzle terminates downwards in a remarkably long sickle-shaped process, which extends below the lower jaw to opposite the angle of the mouth, or in young individuals a little beyond it. The young are farther distinguished by their excessively minute right ventral fin. The description and plate of Plagusia dipterygia, Ruppell, offer no specific distinguishing character. The distance from the muzzle to the point of the sickleshaped process, its length, varies individually from $5\frac{1}{3}$ to $6\frac{1}{2}$ in the total length; in young individuals it is proportionally longer, slightly exceeding $\frac{1}{5}$. The upper orbit is situated in the centre of the head, above the middle of the upper lip; the horizontal diameter is $\frac{1}{4\frac{1}{3}}$ of the length of the head. The lower orbit is thrown farther back above the angle of the mouth; both are of about equal size, and their vertical distance but slightly exceeds the horizontal diameter. The left side of the jaw is toothless with fleshy pa pillular lips; in the right of both appear crowd-

ed fine setaceous teeth. A single nostril appears in front of the lower eye, close to the lip: the tongue is minute, rounded, smooth. The greatest vertical diameter of the body, at the commencement of the anal fin, equals the length of the head; on it appear about 44 series of scales. The latter are elongated oval; those of the body double the size of those of the head. The anterior margin carries upwards of 17 minute spines, rough to the touch; the radical part upwards of 60 radiating lines. A line between the gill-opening and the caudal contains about 85 scales. The lateral line commences at the muzzle, ascends a little above the upper orbit; from thence it is straight to near the upper margin of the opercle, where it makes a very short ascent, and then continues straight, nearly in the middle of the body to the caudal. Above the preopercle it gives off a short vertical branch, which again is divided in three principal branches: an upper which proceeds backwards to the margin of the opercle, a second obliquely downwards over the opercle, and a third, which following the anterior arch of the preopercle despatches a branch backwards to the lower part of the opercle, and terminates on the throat. Above the opercle the lateral line gives off another short branch which rises vertically, and divides in what is called the second lateral line of which the anterior branch proceeds near the base of the dorsal towards the muzzle, the posterior continues near the dorsal to the caudal. The dorsal commences far in front of the eyes at a short distance from the muzzle. The dorsal, caudal and anal rays are undivided, and nearly of equal length, $\frac{1}{8}$ of the head, with the points slightly projecting beyond their membranes. The left ventral is situated at the gill-opening, on a level a little above the anal; the first ray is very short and closely connected to the second; the rest gradually increase in length; the fifth is the longest, $\frac{1}{5}$ of the head and by a membrane throughout connected to the first anal. The stomach is capacious, broad pyriform; the intestinal canal simple, forming two circumvolutions; its length is less than $\frac{2}{3}$ of the total. Single individuals occur at Pinang at all seasons. They are of excellent flavour.

(3803) *Plagusia cynoglossa*, (Buchan Ham.) Var. A. [Syn. *Achirus cynoglossus*, Buchan. Hamilton, 132, 373. Marked *Achirus kukurjibha* in Buchanan's duplicate series of drawings. Inhabits, Bay of Bengal, mouths of the Ganges.]

Syn. Ikan ledah of the Malays.

Left side. Ground-colour pale reddish brown, posterior half of head and the body largely spotted and marbled with blackish brown; dorsal, caudal and anal rays brownish their membranes pale brownish transparent, minutely dotted with black; ventrals whitish. Iris golden, annular, rest bluish black. *Right side.* Brownish white; opercle and abdominal cavity pale bluish.

Var. B.

Left side. Differs from *Var. A* by having 7 or 8 vertical, blackish brown, distant bands not extending over the dorsal and anal; head and intervals with irregular blackish brown spots.

D 100 or 102,
C 10,.....V 4, P 0, Br. VI.
A 76 or 78,

186 or 190.

Inhabits *Sea of Pinang*. Total length: 6 inch. *Left side.* The length of the head is $5\frac{2}{3}$ in the total. The distance from the very bluntly pointed muzzle to the upper eye is $\frac{1}{7\frac{1}{2}}$ of the total length; the point proceeding downwards from the muzzle barely covers the symphysis of the lower jaw; its length equals the distance from the muzzle to the upper eye. Both eyes are excessively minute, like points. The upper one is situated at the anterior third of the head, opposite the middle of the upper lip. The lower is a little farther back, immediately above the posterior third of the upper lip. The distance between both is apparently two diameters. No nostril is distinguishable. The left side of the lips is not papillular; the right completely hides the minute teeth. The greatest vertical diameter of the body, in front of the anal, is $\frac{1}{3}$ in the total length; on it appear 31 to 33 series of scales. The latter are on the body comparatively large, elongated oblong, with about 17 minute spines at the posterior margin, and about 36 radiating lines on the radical portion. There are about 81 on a straight line between the gill-opening and the caudal. The lateral line with its ramifications, resembles that of *P. bilineata*. The length of the pointed caudal is $\frac{1}{2}$ of the head. The distance from the first anal to the first ventral ray equals that between the muzzle and the upper eye, which is nearly thrice that of these fins in *P. bilineata*. In other respects the fins resemble those of the latter species. At Pinang single individuals occur, but rarely, which in addition to their small size, makes them less valued as an article of food.

(3804) *Plagusia trulla*, Cantor.

Syn. Ikan ledah of the Malays.

Left side. Pale dark reddish brown; opercles much darker than the rest; in some individuals a series of short, distant, vertical bluish lines under the anterior half of the dorsal, and above the anterior third of the anal; scales with a dark longitudinal line; posterior margin buff; fins transparent pale brownish, minutely but faintly dotted with black. Iris annular golden; rest bluish black. *Right side.* Brownish white, opercles and abdominal cavity blackish blue.

D 109 or 111,
C 12,..... *left* V 4, *right* 0; P 0, Br. VI.
A 80 or 86,

201 or 209.

Inhabits *Sea of Pinang, Malayan Peninsula.* Total length: 1 ft. *Left side.* The length of the head is $5\frac{1}{4}$ in the total. The distance from the rounded muzzle to the anterior angle of the upper orbit is from $13\frac{1}{3}$ to $\frac{1}{14}$ of the total length. The point proceeding downwards from the muzzle covers the symphysis of the lower jaw; its length equals the distance between the muzzle and upper orbit. The latter is situated a little behind the anterior third of the length of the head, opposite the middle of the upper lip. The horizontal diameter is $10\frac{1}{3}$ in the head. The lower orbit is placed a little farther back, still considerably in front of the angle of the mouth; it is a little smaller than the upper; the vertical distance between both slightly exceeds the horizontal diameter of the upper. Immediately beneath the latter appears a small, but remarkably developed bony protuberance, or spine. A single aperture of the nostril appears a little in front of the lower eye above the lip. The lips are fleshy, but not papillular, otherwise the mouth, tongue and dentition resemble *P. bilineata.* The greatest vertical diameter of the body, towards the middle, is $4\frac{1}{2}$ to $4\frac{2}{3}$ in the total length. It contains 45 series of scales. For the size of the fish the latter are rather small, elongated oval, with about 21 radiating lines at the radical part, and 13 spines at the posterior margin, which is rough to the touch. A straight line between the opercle and the caudal contains about 117. The lateral line and its ramifications resemble *P. bilineata.* The distance between the muzzle and the first dorsal ray, and that between the first ventral and anal ray equal $\frac{1}{2}$ of that between the muzzle and upper eye. The length of the caudal varies from $2\frac{1}{3}$ to $\frac{1}{2}$ of the length of the head. There is but a single ventral, on the left side, connected by a membrane to the anal. But for the absence of the ventral fin, the figure marked *Plagusia abbreviata* in *Illustrations of Indian Zoology*, II. Pl. 94, Fig. 3, might be supposed to represent the present species. Individuals, although never in great numbers, occur at all seasons at Pinang, and are highly valued for their flavour.

(3805) *Plagusia grandisquamis*, Cantor.

Left side. Pale reddish brown; scales with metallic iridescent reflections, a central, dark longitudinal line, and the posterior margin buff; opercle and abdominal cavity bluish black; from above the opercle closely beneath the base of the dorsal a black band, gradually narrowing towards the caudal; from a little behind the abdominal cavity immediately above the base of the anal a similar black band joining the former at the root of the caudal; dorsal and anal pale brownish transparent, minutely dotted with black; caudal black, ventrals white. Iris annular golden, rest minutely dotted with black. *Right side.* Brownish white; opercle and abdominal cavity bluish black.

D 116,
C 10, V 4, P 0, Br. VI.
A 88,
214

Inhabits *Sea of Pinang.* Total length: $7\frac{1}{2}$ inch. *Left side.* The general form is narrow, elongated lanceolate, resembling *Plagusia lingva*, (Buchanan Hamilton.) The length of the head is $5\frac{1}{3}$ in the total. The distance from the oval muzzle to the anterior angle of the upper orbit is $\frac{1}{14}$ of the total length; the point proceeding downwards from the muzzle is broad, barely covering the symphysis of the lower jaw; its length equals the distance between the muzzle and the upper orbit. Both orbits are nearly equal; the upper one is situated at the second fifth of the head opposite the middle of the upper lip; the horizontal diameter is $\frac{1}{10}$ of the length of the head. The lower orbit is placed very little farther back than the upper. The interval between both is excessively narrow, a short linear septum; between the anterior angles of both appears a small pointed, triangular, bony protuberance. The nostril has a single aperture in front of the lower eye, above the upper lip. The lips are fleshy, not papillular; the excessively minute teeth on the right side are completely hid from view. The tongue is linear, smooth. The greatest vertical diameter, at the anterior third of the body, equals the length of the head. On it appear 17 series of remarkably large scales, of a broad oval form. The length of the largest is $\frac{1}{5}$ of the head, their breadth $\frac{1}{10}$; at the radical part appear upwards of 50 radiating lines; at the posterior margin 36 to 38 fine spines, rough to the touch. A straight line between the opercle and caudal contains 59 scales. The lateral line and its ramifications resemble those of *P. bilineata.* The dorsal commences at a distance from the muzzle of $\frac{1}{2}$ of that from the latter to the upper eye; the longest rays, as well as the pointed caudal, is $\frac{1}{3}$ of the head. The distance between the left ventral and the anal is $\frac{1}{2}$ of that between the muzzle and the upper eye, Both ventrals are nearly equal, $\frac{1}{3}$ of the head; the last ray of the left ventral is throughout united to the first anal. In other respects the fins resemble those of *P. bilineata.* A single individual occurred at Pinang in December 1842. The scales were deciduous, probably from decay. The fishermen were not acquainted with the species.

(3806) *Plagusia lingva*, (Buchanan Hamilton.)

Syn. Cynoglossus lingva, Buchan. Ham. 32, 365. [Marked *dexeiris* [illegible] in Buchanan's duplicate series of drawings.]
'Ikan ledah' of the Malays.

Left side. Reddish brown; the scales with golden iridescent reflections, a dark longitudinal central line, and the posterior margin buff; oper-

cle blackish blue; sides with distant rounded and irregular blackish brown spots; dorsal and anal pale brownish grey, transparent, minutely dotted with black; the dorsal immediately in front of the caudal, and the latter itself, black; ventrals white, Iris golden, annular; rest blackish blue. *Right side.* Brownish white; abdominal cavity blackish blue.

D 137,
C V 10, 4. P 0, Br. VI.
A 107.

254.

Inhabits *Sea of Pinang*, Bay of Bengal, Gangetic estuaries. Total length: 1 ft. *Left side.* The length of the head is $5\frac{1}{3}$ in the total. The distance from the oval muzzle to the anterior angle of the upper orbit is $11\frac{1}{3}$ in the total length; the point proceeding downwards from the muzzle projects a little beyond the symphysis of the lower jaw; its length equals the distance between the muzzle and the upper orbit. The latter is situated in the centre of the length of the head, opposite the middle of the upper lip; the horizontal diameter is $\frac{1}{4}$ of the length of the head. The lower orbit is placed farther back a little in front of the angle of the mouth; it is slightly smaller than the upper one. The vertical distance between the two equals the diameter of the upper. Between both appears a very distinct oval aperture, according to Buchanan Hamilton the posterior aperture of the nostril, which has another above the upper lip in front of the lower eye The mouth, tongue, and dentition agree with *P. grandisquamis*. The greatest vertical diameter, at the anterior third of the body is $6\frac{2}{3}$ in the total length. On it appear 31 series of elongated, irregularly oval scales with upwards of 37 radiating lines at the radical part. Those of the anterior part of the body have the centre of the posterior margin very finely ciliated, not rough to the touch; in the rest of the scales this margin is smooth and bluntly pointed. A straight line between the opercle and caudal contains about 100 scales. The lateral line and its ramifications resemble those of *P. bilineata*. The dorsal commences very close to the point of the muzzle, $\frac{1}{6}$ of the distance from the latter to the upper orbit; the rays slowly increase towards the caudal, the longest being $\frac{1}{3}$ of the head. The caudal terminates in a very sharp point; its length is $\frac{1}{2}$ of the head. The distance between the first, left, ventral and the anal ray is scarcely $\frac{1}{3}$ of that between the point of the muzzle and the upper orbit. The right ventral is smaller and so near the left, which is closely connected with the anal, that Buchanan Hamilton overlooked both. In other respects the fins resemble those of *P. bilineata*. Single individuals occur, but rarely, at Pinang.

(3807) *Plagusia potous*, Cuvier.

Syn. Russell, I. XIII. Jerree Potoo. D.
Plagusia potous, Cuvier, R. A. II. 344 (1).
Ikan ledah of the Malays.

Left side. Lighter or darker copper-red; the scale with strong metallic iridescent reflections; opercle and abdominal cavity pale blackish blue; fins transparent pale brownish, minutely dotted with brown; caudal blackish; ventrals whitish. Iris annular, pale golden; rest blackish blue; superior margin of the upper orbit and lower of the inferior with a buff crescent-shaped membrane *Right side.* Brownish white; opercle and abdominal cavity pale bluish.

D 126 or 127.
C 10,..... V 4, P 0, Br. VI.
A 94 or 95.

230 or 232.

Inhabits *Sea of Malayan Peninsula and Islands*, Coromandel. Total length: 1 ft. 2 inch. *Left side.* The length of the head is $5\frac{1}{4}$ in the total. The distance from the centre of the oval muzzle to the anterior angle of the upper orbit is from $11\frac{1}{3}$ to $\frac{1}{12}$ of the total length. The point proceeding downwards from the muzzle covers the symphysis of the lower jaw, or is a little shorter; its length equals the distance between the muzzle and the upper orbit. The latter is situated a little in front of the centre of the length of the head, opposite the middle of the upper lip; the horizontal diameter is $\frac{1}{11}$ of the length of the head. The lower orbit, in size equals the upper; it is placed little farther back, considerably in front of the angle of the mouth. The vertical distance between both equals the horizontal diameter. In front of the lower orbit, above the lip, appear two small apertures of the nostrils, separated by a narrow membranous septum; the lower is oval, double the size of the circular upper one, which opens under a small bony protuberance. The mouth, tongue, and teeth resemble those of *P. grandisquamis*. The greatest verticle diameter of the body, at the anterior third, is $5\frac{1}{2}$ in the total length. On it appear 23 series of oval scales, of which the largest are $\frac{1}{7}$ of the length of the head; their breadth $\frac{1}{14}$. The radicle part is marked with upwards of 46 radiating lines; the posterior margin with 36 to 38 very minute spines, barely perceptible to the touch. A straight line between the opercle and the caudal contains 69 scales. The lateral line and its ramifications resemble those of *P. bilineata*. The fins resemble those of *P. lingua*. The description of Russell gives 148 dorsal rays which probably is a misprint instead of 128. At all events there is a great discrepancy between the description and the plate which represents 165 dorsal and 155 anal rays. The form of all the fins is incorrect. At Pinang this species occurs, although never in great numbers, at all

seasons. It is of excellent flavour, and like *Plagusia trulla*, passes at European tables under the denomination of "Sole." With the exception of *Plagusia grandisquamis*, which was not observed alive, the other species are all distinguished for their tenacity of life. The fishermen at Pinang assert that some species of *Plagusia* shoal at certain seasons.

ORDER PHARYNGOGNATHI. SUBORDER PHARYNGOGNATHI ACANTHOPTERYGII.

Fam. SCAROIDÆ.
